Maundrel, in his Travels, says there were but 16 large trees remaining when he visited mount Libanus, some of which were of a prodigious bulk, but that there were many more young ones of a smaller size: he measured one of the largest, and found it to be 12 yards six inches in girth, and yet sound, and 37 yards in the spread of its boughs. At about five or six yards from the ground it was divided into five limbs, each of which was equal to a great tree. What Maundrel has related was confirmed by a gentleman who was there in the year 1720, with this difference only, viz. in the dimensions of the branches of the largest tree; which he measured, and found to be 22 yards diameter. Now whether Mr. Maundrel meant 37 yards in circumference of the spreading branches, or the diameter of them, cannot be determined by his words; yet either of them well agrees with this last account.

12. The larix, or larch-tree, with deciduous leaves, and oval obtuse cones. It grows naturally upon the Alps and Apennines, and of late has been very much propagated in Britain. It is of quick growth, and the trunk rises to 50 feet or more; the branches are slender, their ends generally hanging downward. In the month of April the male flowers appear, which are disposed in form of small cones; the female flowers are collected into oval obtuse cones, which in some species have bright purple tops, and in others they are white: these differences are accidental; the cones are about an inch long, obtuse at their points; the scales are smooth, and lie over each other: under each scale there are generally lodged two seeds, which have wings. There are two other varieties of this tree, one of which is a native of America, and the other of Siberia. The cones of the American kind which have been brought to Britain, seem in general to be larger than those of the common sort.

From the larch-tree is extracted what we erroneously call Venice turpentine. This substance, or natural balsam, flows at first without incision; and when it has done dropping, the poor people who wait in the fir woods make incisions at about two or three feet from the ground into the trunks of the trees, into which they fix narrow troughs about 20 inches long. The end of these troughs is hollowed like a ladle; and in the middle is a small hole bored for the turpentine to run into the receiver which is placed below it. As the gummy substance runs from the trees, it passes along the sloping gutter or trough to the ladle, and from thence runs through the holes into the receiver. The people who gather it visit the trees morning and evening from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, Venice turpentine is clear like water, and of a yellowish-white; but, as it grows older, it thickens and becomes of a citron-colour. It is procured in the greatest abundance in the neighbourhood of Lyons; and in the valley of St. Martin, near St. Lucern, in Switzerland.

All the sorts of pines are propagated by seeds produced in hard woody cones. The way to get the seeds out of these cones is, to lay them before a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good for some years; so that the surest way of preserving them is to let them remain in the cones till the time for sowing the seeds. If the cones are kept in a warm place in summer, they will open and emit the seeds; but if they are not exposed to the heat, they will remain close for a long time. The best season for sowing the pines is about the end of March. When the seeds are sown, the place should be covered with nets to keep off the birds; otherwise, when the plants begin to appear with the husk of the seed on the top of them, the birds will peck off the tops, and thus destroy them.

From the first species is extracted the common turpentine, much used by farriers, and from which is drawn the oil of that name. The process of making pitch, tar, resin, and turpentine, from these trees, is this: In the spring time, when the sap is most free in running, they pare off the bark of the pine-tree, to make the sap run down into a hole which they cut at the bottom to receive it. In the way, as it runs down, it leaves a white matter like cream, but a little thicker. This is very different from all the kinds of resin and turpentine in use; and is generally sold to be used in the making of flambeaux, instead of white bees'-wax. The matter that is received in the hole at the bottom is taken up with ladles, and put in a large basket; a great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, adding a large quantity of water. They distil this as long as any oil is seen swimming on the water. This oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine. The remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all they can from the sap of the tree, they cut it down; and, hewing the wood into billets, they fill a pit dug in the earth with these billets; and setting them on fire, there runs from them, while they are burning, a black thick matter. This naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil. If this hole is made too large, it sets the whole quantity of the tar on fire; but if small enough, it runs quietly out.

The tar, being thus made, is put up in barrels; and if it is to be made into pitch, they put it into large boiling-vessels, without adding any thing to it. It is then suffered to boil awhile, and being then let out, is found when cold to be what we call pitch.

A decoction of the nuts or seeds of the first species in milk, or of the extremities of the branches pulled in spring, is said, with a proper regimen, to cure the most inveterate scurvy. The wood of this species is not valued; but that of the Scots pine is superior to any of the rest. It is observable of the Scots pine, that when planted in bogs, or in a moist soil, though the plants make great progress, yet the wood is white, soft, and little esteemed; but when planted in a dry soil, though the growth of the trees is there very slow, yet the wood is proportionably better. Few trees have been applied to more uses than this. The tallest and straightest are formed by nature for masts to our navy. The timber is resinous, durable, and applicable to numberless domestic purposes, such as flooring and wainscoting of rooms, making of beds, chests, tables, boxes, &c. From the trunk and branches of this, as well as most others of the pine tribe, tar and pitch are obtained. By incision, barras, Burgundy pitch, and turpentine, are acquired and prepared. The resinous roots are dug out of the ground in many parts of the Highlands, and, being divided into small splinters, are used by the inhabitants to burn instead of candles. At Loch-Broom, in Ross-shire, the fishermen make ropes of the inner bark; but hard necessity has taught the inhabitants of Sweden, Lapland, and Kamtschatka, to convert the same into bread. To effect this, they, in the spring season, make choice of the tallest and fairest trees; then stripping off carefully the outer bark, they collect the soft, white, succulent, interior bark, and dry it in the shade. When they have occasion to use it, they first toast it at the fire, then grind, and after steeping the flour in warm water to take off the resinous taste, they make it into thin cakes, which are baked for use. On this strange food the poor inhabitants are sometimes constrained to live for a whole year; and we are told, through custom, become at last even fond of it. Linnæus remarks, that this same barkbread will fatten swine; and humanity obliges us to wish, that men might never be reduced to the necessity of robbing them of such a food. The interior bark, of which the abovementioned bread is made, the Swedish boys frequently peel off the trees in the spring, and eat raw with a greedy appetite. From the cones of this tree are prepared a diuretic oil, like the oil of turpentine, and a resinous extract, which has similar virtues with the balsam of Peru. An infusion or tea of the buds is highly commended as an antiscorbutic. The farina, or yellow powder, of the male flowers, is sometimes in the spring carried away by the winds, in such quantities, where the trees abound, as to alarm the ignorant with the notion of its raining brimstone. The tree lives to a great age; Linnæus affirms, to 400 years.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army for mending the ways, for working on intrenchments and fortifications, and for making mines and approaches. The soldiers are likewise employed for all these purposes. Most of the foreign regiments of artillery have half a company of pioneers, well instructed in that important branch of duty. Our regiments of infantry and cavalry have about twenty pioneers each, provided with aprons, hatchets, saws, spades, and pick-axes. Each pioneer must have an ax, a saw, and an apron; a cap with a leather crown, and a black bear-skin front, on which is to be the king's crest in white, on a red ground; and the number of the regiment is to be on the back part of it.

PIP, or Pep, pepia, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding. It usually arises from want of water, or from drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with salt. Hawks are particularly liable to this disease, especially from feeding on stinking flesh.

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other fluids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are commonly made of oak or elder. Those of iron are cast in forges; their usual length is about two feet and a half: several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augurs, of different sizes, beginning with a less, and then proceeding with a larger successively; the first being pointed, the rest formed like spoons, increasing in diameter, from one to six inches or more: they are fitted into the extremities of each other, and are sold by the foot.

Pipe-Boring. AA, Plate Perambulator, &c. fig. 4, are two beams laid on each side of a pit, into which the chips are to fall. Upon the edges of these, the wheels of a frame DE run. This frame has four pieces, *ddaa*, across it; and two windlases, *bb*, which have chains round them, going over the piece of timber F which is to be bored. The two end-pieces *dd* have uprights *ee* in them; between which the tree is laid, and is secured with wedges in different places as the occasion requires. G is a piece lying across the two beams AA: this is connected with the frame DE by two iron bars *ff*, which are fastened to it; and go through holes in the piece *d*, and are held there by pins put through holes in both. The piece G has two uprights in it, between which is a brass pulley to support the weight of the boring-bar H. *ghi* is a wheel, with handles on its circumference to turn it by; on its axis I a rope is coiled; one end of which goes over a pulley (not seen), and is fastened to the carriage DE. At *i* the other end goes over a similar pulley, and is tied to the other end of the carriage DE. The machine is put into some place where there is a crane, by which the tree can be lifted on to the carriage; first withdrawing the carriage from the boring-bar, by turning the wheel from *g* to *i*, and separating it from the piece G by taking out the pins. It is then wedged into its place, and secured by the windlases *bb*. The wheel is next turned back, the carriage drawn up to the borer, and the piece G pinned in. The machine (either horses, water, steam, &c.) which turns the borer is then set to work; and a man constantly attends at the wheel *ghi*, to draw the pipe up to the borer. The use of the wheel in the piece G is, to support the borer just where it enters the pipe, and make it work steady. When the pipe is bored through, it is withdrawn, and another tree is placed on the carriage as before.

Pipes *of an Organ*. See Organ.

Pipes, *tobacco*, are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use pipes three or four feet long, made of rushes, or of wood bored, at the end whereof they fix a kind of pot of baked earth, which serves as a bowl, and which they take off after smoking.

Pipe also denotes a vessel or measure for wine, containing 126 gallons.

Pipe-Office is an office wherein a person called the clerk of the pipe makes out leases of crown lands, by warrant from the lord-treasurer, or commissoners of the treasury, or chancellor of the exchequer. The clerk of the pipe makes out also accounts of sheriffs, &c. and gives the accomptants their quietus est. To this office are brought all accounts which pass the remembrancer's office, and remain there, that if any stated debt is due from any person, the same may be drawn down into the great roll of the pipe; upon which the comptroller issues out a writ, called the summons of the pipe, for recovery thereof; and if there are no goods or chattels, the clerk then draws down the debts to the lord-treasurer's remembrancer, to write estreats against their lands. All tallies which vouch the payment of any sum contained in such accounts, are examined and allowed by the chief secondary of the pipe. Besides the chief clerk in this office, there are eight attorneys, or sworn clerks, and a comptroller.

PIPER, PEPPER; a genus of the trigynia order, in the diandria class of plants. There is no calyx or corolla; the berry is one-seeded. There are 60 species, of which the most remarkable is the siriboa, with oval, heart-shaped, nerved leaves, and reflexed spikes. This is the plant which produces the pepper so much used in food. It is a shrub whose root is small, fibrous, and flexible; it rises into a stem, which requires a tree or prop to support it. Its wood has the same sort of knots as the vine; and when it is dry, it exactly resembles the vine-branch. The leaves, which have a strong smell and a pungent taste, are of an oval shape; but they diminish towards the extremity, and terminate in a point. From the flower-buds, which are white, and are sometimes placed in the middle and sometimes at the extremity of the branches, are produced small berries resembling those of the currant. Each of these contains between 20 and 30 corns of pepper; they are commonly gathered in October, and exposed to the sun seven or eight days. The fruit, which was green at first, and afterwards red, when stripped of its covering assumes the appearance it has when we see it. The largest, heaviest, and least shrivelled, is the best. The pepper-plant flourishes in the islands of Java, Sumatra, and Ceylon, and more particularly on the Malabar coast. It is not sown, but planted; and great nicety is required in the choice of the shoots. It produces no fruit till the end of three years; but bears so plentifully the three succeeding years, that some plants yield between six and seven pounds of pepper. The bark then begins to shrink; and the shrub declines so fast, that in 12 years time it ceases bearing.

Betle, or betel, is a species of this genus. It is a creeping and climbing plant like the ivy; and its leaves a good deal resemble those of the citron, though they are longer and narrower at the extremity. It grows in all parts of India, but thrives best in moist places. The natives cultivate it as we do the vine, placing props for it to run and climb upon; and it is a common practice to plant it against the tree which bears the areca nut. At all times of the day, and even in the night, the Indians chew the leaves of the betel, the bitterness of which is corrected by the areca that is wrapped up in them. There is constantly mixed with it the chinam, a kind of burnt lime made of shells. The rich frequently add perfumes, either to gratify their vanity or their sensuality.

It would be thought a breach of politeness among the Indians to take leave for any long time, without presenting each other with a purse of betel. It is a pledge of friendship that relieves the pain of absence. No one dares to speak to a superior unles his mouth is perfumed with betel; it would even be rude to neglect this precaution with an equal. The women of gallantry are the most lavish in the use of betel. Betel is taken after meals; it is chewed during a visit; it is offered when you meet, and when you separate; in short, nothing is to be done without betel. If it is prejudicial to the teeth, it assists and strengthens the stomach. At least, it is a general fashion that prevails throughout India.

The piper nigrum, or black pepper, and the piper longum, or long pepper, of Jamaica, with some other species, are indigenous, and known by the names of joint wood, or peppery elders. The first bears a small spike, on which are attached a number of small seeds of the size of mustard. The whole of the plant has the exact taste of the East India black pepper. The long-pepper bush grows taller than the nigrum. The leaves are broad, smooth, and shining; the fruit is similar to the long pepper of the shops, but smaller. The common people in Jamaica season their messes with the black pepper. To preserve both, the fruit may be slightly scalded when green, then dried, and wrapped in paper.

PIPRA, the manakin, a genus of birds of the order of passeres. Latham describes 25 different species, and five varieties. The general character of the genus is, that the bill is short, strong, hard, and slightly incurvated, and the nostrils are naked. The middle toe is connected to the outer as far as the third joint; this character, however, is not altogether universal, some of the species differing in this particular. The tail is short. This genus has a considerable resemblance to the genus parus, or titmouse. They are supposed to inhabit South America only; but this is not true, for Mr. Latham assures us that he has seen many of those species which he has described which came from other parts, but which nevertheless certainly belong to this genus.

1. The pipra rupicola, or crested manakin, is about the size of a small pigeon, being about ten or twelve inches long. The bill is about an inch and a quarter long, and of a yellowish colour. The head is furnished with a double round crest; the general colour of the plumage is orange, inclining to saffron; the wing-coverts are loose and fringed. The female is altogether brown, except the under wing-coverts, which are of a rufous orange; the crest is neither so complete nor rounded as that of the male. Both males and females are at first grey, or of a very pale yellow, inclining to brown. The male does not acquire the orange colour till the second year, neither does the female the full brown. See Plate Nat. Hist. fig. 337. This beautiful species inhabits various parts of Surinam, Cayenne, and Guiana, in rocky situations; but is no where so frequent as in the mountain Luca, near the river Oyapoc, and in the mountain Courouayé, near the river Aprouack, where they build in the cavernous hollows and the darkest recesses.

2. The next species Mr. Latham calls the tuneful manakin. Its length is four inches; the bill is dusky, the forehead yellow, and the crown and nape blue; the chin, sides of the head below the eyes, and the throat, are black; the upper part of the back, the wings, and the tail, are dusky black. It is a native of St. Domingo, where it has gained the name of organiste from its note, forming the complete octave in the most agreeable manner, one note successively after another. It is said not to be uncommon, but not easy to be shot, as like the creeper, it perpetually shifts to the opposite part of the branch from the spectator's eye, so as to elude his vigilance.

3. The albifrons inhabits South America. See Plate Nat. Hist. fig. 336. There are about 30 species.

PIRATE. By stat 28 H. VIII. c. 15, all treasons, felonies, robberies, murders, and confederacies committed upon the sea, or in any haven, creek, or place where the admiral has jurisdiction, shall be tried in such shires or places as the king shall appoint by his commission in like forms, as if such offence had been committed upon land, and according to the course of the common law, and the offenders shall suffer death without benefit of clergy. And by stat. 6 Geo. I, made perpetual, it is enacted, that if any of his majesty's natural-born subjects, or denizens of this kingdom, shall commit any piracy or robbery, or any act of hostility, against other his majesty's subjects upon the sea, under colour of any commission from any prince or state, or pretence of authority from any person whatsoever, such offender shall be deemed to be a pirate, felon, and robber; and being duly convicted thereof according to this act, or the aforesaid act of 23 H. VIII, shall have and suffer such pains of death, loss of lands, goods, and chattels, as pirates, felons, and robbers upon the seas, ought to have and suffer. By 18 Geo. II. c. 30. persons committing hostilities, or aiding enemies at sea, may be tried as pirates. Piracies at sea are excepted out of the general pardon, by 20 Geo. II. c. 52.

PIRATE'S GOODS, go to the admiral by grant; but not piratical goods, which go to the king if the owner is not known.

PISCES, in astronomy, the twelfth sign or constellation of the zodiac. The stars in Pisces, in Ptolemy's catalogue, are 38; in Tycho's, 33; and in the Britannic catalogue, 109.

PISCIDIA, a genus of the decandria order, in the diadelphia class of plants. The stigma is acute; the legume winged four ways. There are two species, viz. 1. The erythrina or dog-wood tree. This grows plentifully in Jamaica, where it rises to the height of twenty-five feet or more; the stem is almost as large as a man's body, covered with a light-coloured smooth bark, and sending out several branches at the top without order. The flowers are of a dirty-white colour; they are succeeded by oblong pods which contain the seeds. 2. The Carthaginiensis, with oblong oval leaves, is also a native of the West Indies. It differs from the former only in the shape and consistence of the leaves, which are more oblong and stiffer; but in other respects they are very similar. Both species are easily propagated by seeds; but require artificial heat to preserve them in this country. The negroes in the West Indies make use of the bark of the first species to intoxicate fish. When any number of gentlemen have an inclination to divert themselves with fishing, or, more properly speaking, with fish-hunting, they send each of them a negro-slave to the woods, in order to fetch some of the bark of the dog-wood tree. This bark is next morning pounded very small with stones, put into old sacks, carried into rocky parts of the sea, steeped till thoroughly soaked with salt water, and then well squeezed by the negroes to express the juice. This juice immediately colours the sea with a reddish hue; and, being of a poisonous nature, will in an hour's time make the fishes, such as groopers, rock-fish, old-wives, Welshmen, &c. so intoxicated, as to swim on the surface of the water, quite heedless of the danger; the gentlemen then send in their negroes, who pursue, both swimming and diving, the inebriated fishes, till they catch them with their hands; their masters in the mean time standing by, on high rocks, to see the pastime. It is remarkable, that though this poison kills millions of the small fry, it has never been known to impart any bad quality to the fish which have been caught in consequence of the intoxication. The wood of this tree, although pretty hard, is only fit for fuel.

PISCIS VOLANS, a small constellation of the southern hemisphere, unknown to the antients, and invisible to us in these northern regions.

PISOLITE, a mineral found at Carlsbad in Bohemia. It has the form of round masses composed of concentric layers, and containing a grain of sand in their centre. Colour white, often greyish, reddish, or yellowish. The round bodies are collected together like a bunch of grapes.

PISONIA, a genus of the polygamia diœcia class of plants, the corolla whereof is of an infundibuliform shape; the tube is short; the limb is semiquinquefid, acute, and patulous; the fruit is an oval quinquangular capsule, formed of five valves, and containing only one cell; the seed is single, smooth, and ovato-oblong. There are five species, trees of the West Indies.

PISTACHIA, *turpentine-tree, pistachia-nut, mastich-tree*; a genus of the pentandria order, in the diœcia class of plants. The male is an ament.; cal. five-cleft; cor. none; fem. distinct; cal. trifid; cor. none; styles two; drupe one-seeded. There are six species; of which the most remarkable are: 1. The terebinthus, or pistachia-tree. This grows naturally in Arabia, Persia, and Syria, whence the nuts are annually brought to Europe. In those countries it grows to the height of 25 or 30 feet; the bark of the stem and old branches is of a dark russet colour, but that of the young branches is of a light brown. Some of these trees produce male and others female flowers, and some have both male and female on the same tree. The male flowers come out from the sides of the branches in loose bunches or catkins. They have no petals, but five small stamina. The female flowers come out in clusters from the sides of the branches; they have no petals; but a large oval germen supporting three reflexed styles, and are succeeded by oval nuts. 2. The lentiscus, or common mastich-tree, grows naturally in Portugal, Spain, and Italy. Being an evergreen, it has been preserved in this country in order to adorn the green-houses. In the countries where it is a native, it rises to the height of eighteen or twenty feet. 3. The orientalis, or true mastich-tree of the Levant, from which the mastich is gathered, has been confounded by most botanical writers with the lentiscus, or common mastich-tree, above described, though there are considerable differences between them.

The first species is propagated by its nuts; which should be planted in pots filled with light kitchen-garden earth, and plunged into a moderate hotbed to bring up the plants. The second sort is commonly propagated by laying down the branches, though it may also be raised from the seed in the manner already directed for the pistachia-nut tree; and in this manner also may the true mastich-tree be raised. But this, being more tender than any of the other sorts, requires to be constantly sheltered in winter, and to have a warm situation in summer.

Pistachia-nuts have a pleasant, sweet, unctuous taste, resembling that of almonds; and they abound with a sweet and well-tasted oil, which they yield in great abundance on being pressed after bruising them; they are reckoned amongst the analeptics, and are wholesome and nutritive, and are by some esteemed very proper to be prescribed by way of restoratives, eaten in small quantity, to people emaciated by long illness.

PISTIA, a genus of the monadelphia octandria class and order. There is no calyx; the corolla is one-petalled, tongue-shaped, entire; anthers six or eight; style one; capsule one-celled. There is one species, an aquatic of Senegal.

PISTIL. See Botany.

PISTON. See Pump.

PISUM, pea; a genus of the decandria order, in the diadelphia class of plants. The style is triangular, above one-celled, pubescent; calyx has the two upper segments shorter. The species are, 1. The sativum, or garden-pea. 2. The maritimum, or sea-pea, with footstalks which are plain on their upper side, an angular stalk, arrow-pointed stipulæ, and footstalks bearing many flowers. 3. The ochrus, with membranaceous running footstalks, having two leaves and one flower upon a footstalk.

There is a great variety of garden-peas now cultivated in Britain, which are distinguished by the gardeners and seedsmen, and have their different titles; but as great part of these have been seminal variations, so, if they are not very carefully managed, by taking away all those plants which have a tendency to alter before the seeds are formed, they will degenerate into their original state; therefore all those persons who are curious in the choice of seeds, look carefully over those which they design for seeds at the time when they begin to flower, and draw out all the plants which they dislike from the other. This is what they call roguing their peas; meaning the taking out all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which, they always do it before the flowers open. By thus diligently drawing out the bad, reserving those which come earliest to flower, they have greatly improved their peas of late years, and are constantly endeavouring to get forwarder varieties; so that it would be to little purpose in this place to attempt giving a particular account of all the varieties now cultivated; we shall therefore only mention the names by which they are commonly known, placing them according to their time of coming to the table, or gathering for use.

The golden hotspur.	Nonpareil.
The charlton.	Sugar dwarf.
The Reading hotspur.	Sickle pea.
Master's hotspur.	Marrowfat.
Essex hotspur.	Rose or crown pea.
The dwarf pea.	Rounceval pea.
The sugar pea.	Grey pea.
Spanish Morotto	Pig pea.

Among the new varieties we may specify an uncommonly fine species of marrowfat, raised by that truly philosophical gardener, R. P. Knight, esq. and to be had at Mr. Mason's, Fleet-street.

The English sea-pea is found wild upon the shore in Sussex and several other counties in England, and is undoubtedly a different species from the common pea.

The third sort is annual, and grows naturally among the corn in Sicily and some parts of Italy, but is here preserved in botanic gardens for the sake of variety. It has an angular stalk, rising near three feet high; the leaves stand upon winged footstalks, each sustaining two oblong lobes. The flowers are of a pale yellow colour, shaped like those of the other sort of pea, but are small, each footstalk sustaining one flower; these are succeeded by pods about two inches long, containing five or six roundish seeds, which are a little compressed on their sides. These are by some persons eaten green; but unless they are gathered very young, they are coarse, and at best not so good as the common pea. It may be sown and managed in the same way as the garden pea.

PITCAIRNIA, a genus of the hexandria monogynia class and order. The calyx is three-leaved, half-superior; corolla three-petalled, with a scale at the base of each; stigmas three, contorted; capsules three, opening inwards; seeds winged. There are three species, herbs of the West Indies.

PITCH, a tenacious oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various other arts; or it is more properly tar, inspissated by boiling it over a slow fire. See Pinus.

Pitch, *mineral*, has a strong resemblance to common pitch. Colour black, dark-brown, or reddish. Specific gravity from 1.45 to 2. Does not stain the fingers. On a white iron it flames with a strong smell, and leaves a quantity of grey ashes. See Bitumen.

PITCHSTONE. This stone, which occurs in different parts of Germany, France, and other countries, has obtained its name from some resemblance which it has been supposed to have to pitch. It is most usually in amorphous pieces of different sizes.

Its fracture is conchoidal and uneven, and sometimes approaches the splintery. Exceedingly brittle; it yields even to the nail of the finger. Specific gravity 2.3 to 1.6. Its colours are numerous; greyish black, bluish grey, green, red, yellow of different shades. Sometimes several of these colours appear together in the same stone. A specimen of pitchstone, analysed by Mr. Klaproth, contained

73.00	silica
14.50	alumina
1.00	lime
1.00	oxide of iron
0.10	oxide of manganese
1.75	soda
8.50	water.
99.85	

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees. See Plants, *physiology of.*

PITTOSPORUM, in botany, a genus of the monogynia order, in the pentandria class of plants. The calyx is pentaphyllous, inferior, and deciduous. The petals are five in number; the style thread-shaped; the capsule somewhat angular, trilocular, and containing three or four angulated seeds, adhering to the capsule by means of a liquid resin in the loculaments. Of this there are three species, viz. 1. Tenuifolium. 2. Umbellatum. 3. Coriaceum. The first and second are natives of the Cape of Good Hope; the third grows in Madeira, and flowers in May and June.

PITUITARY Gland. See Anatomy.

PLACENTA. See Anatomy and Midwifery.

PLAGIANTHUS, a genus of the class and order monadelphia dodecandria. The calyx is five-cleft; petals five; berry. There is one species, a native of New Zealand.

PLAGUE, Pestilence, or Pestilential fever. See Medicine.

Plague-water, one of the compound waters of the shops, distilled from mint, rosemary, angelica-roots, &c.

PLAIN, in general, an appellation given to whatever is smooth and even, or simple, obvious, and easy to be understood; and, consequently, stands opposed to rough, enriched, or laboured.

A plain figure, in geometry, is an uniform surface; from every point of whose perimeter, right lines may be drawn to every other point in the same.

A plain angle is one contained under the two lines or surfaces, in contradistinction to a solid angle. The doctrine of plain triangles, as those included under three right lines, is termed plain trigonometry. See Trigonometry.

Plain chart. See Chart.

Plain sailing. See Navigation.

Plain scale. See Scale.

Plain table, in surveying, a very simple instrument, whereby the draught of a field is taken on the spot, without any future protraction. It is generally of an oblong rectangular figure, and supported by a fulcrum, so as to turn every way by means of a ball and socket. It has a moveable frame which serves to hold fast a clean paper; and the sides of this frame, facing the paper, are divided into equal parts every way. It has also a box with a magnetical needle, and a large index with two sights; and, lastly, on the edge of the frame, are marked degrees and minutes. See Surveying.

Plain number, is a number that may be produced by the multiplication of two numbers into one another; thus 20 is a plain number produced by the multiplication of 5 into 4.

Plain place, locus planus, or locus ad planum, among the antient geometricians, denoted a geometrical locus, when it was a right line or a circle, in opposition to a solid place, which was an ellipsis, parabola, or hyperbola. These the moderns distinguished into loci ad rectum, and loci ad circulum.

Plain problem, in mathematics, is such a problem as cannot be solved geometrically, but by the intersection either of a right line and a circle, or of the circumferences of two circles; as, given the greatest side, and the sum of the other two sides of a right-angled triangle, to find the triangle, as also to describe a trapezium that shall make a given area of four given lines. Such problems can only have two solutions, in regard a right line can only cut a circle, or one circle cut another, in two points.

PLAISTER *of Paris*. See Sulphat of lime.

PLAN, in general, denotes the representation of something drawn on a plane; such are maps, charts, ichnographies, &c. See Map, Chart, &c.

The term plan, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot, into apartments, rooms, passages, &c. See Architecture.

PLANARIA, a genus of vermes intestina; the generic character is, body gelatinous, flattish, with a double ventral pore, mouth terminal; this genus contains many species, and is divided into sections.

The section A is without eyes; planaria gulo, body long, pellucid, and truncate before; inhabits stagnant water, under duck-weed; body grey; the margin all round is tesselate with very fine striæ: it swallows the cyclidia which inhabit the same waters, and after a time discharges them again. Planaria operculata inhabits the sandy shores, and among fuci in the bays of Norway; something resembles a coffee berry; and moves by bending its margin, and by means of its marginal folds fixes itself to and ascends other bodies. The section B, with a single eye: C with two eyes; D with three eyes, and E with four eyes.

PLANE. See Geometry.

Plane, in joinery, an edged tool, or instrument for paring and shaving of wood smooth. It consists of a piece of wood, very smooth at bottom, as a stock or shaft; in the middle of which is an aperture, through which a steel-edge, or chisel, placed obliquely, passes, which being very sharp, takes off the inequalities of the wood it is slid along. Planes have various names, according to their various forms, sizes, and uses; as 1. The fore-plane, which is a very long one, and is usually that which is first used; the edge of its iron or chisel is not ground straight, but rises with a convex arch in the middle; its use is to take off the greater irregularities of the stuff, and to prepare it for the smoothing-plane. 2. The smoothing-plane is short and small, its chisel being finer; its use is to take off the greater irregularities left by the fore-plane, and to prepare the wood for the jointer. 3. The jointer is the longest of all; its edge is very fine, and does not stand out above a hair's breadth; it is chiefly used for shooting the edge of a board perfectly straight, for jointing tables, &c. 4. The strike-block, which is like the jointer, but shorter; its use is to shoot short joints. 5. The rabbit-plane, which is used in cutting the upper edge of a board, straight or square, down into the stuff, so that the edge of another cut after the same manner, may join in with it, on the square; it is also used in striking facias on mouldings; the iron or chisel of this plane is as broad as its stock, that the angle may cut straight, and it delivers its shavings at the sides, and not at the top, like the others. 6. The plough, which is a narrow rabbit-plane, with the addition of two staves, on which are shoulders; its use is to plow a narrow square groove on the edge of a board. 7. Moulding-planes, which are of various kinds, accommodated to the various forms and profiles of the moulding; as the round-plane, the hollow-plane, the ogee, the snipe's bill, &c. which are all of several sizes, from half an inch to an inch and a half.

PLANET. See Astronomy.

PLANETARIUM, an astronomical machine, made to represent the motions of the planets, and their satellites, as they really are in nature. We have in some degree explained the theory of the planetarium, under the article Orrery; we shall now describe a perspective view of the machine itself, and shew the nature and structure of the wheels by which the motion of the whole is produced. See Plate Planetarium.

In the planetarium exhibited in the plate, A represents the Sun, which is fixed firmly to a wire *a*, and has no motion; B is the planet Mercury, revolving round the Sun; D is the planet Venus; E represents the Earth, and *e* the Moon revolving round it; *f* is a segment of brass called the Earth's terminator, which shews that all the parts of the Earth behind it are not illuminated by the Sun; F is the planet Mars; G, Jupiter and his four satellites; H, Saturn, with his Ring and seven satellites; K the Herschel, and six satellites. L is a small winch, which when turned gives motion to Mercury and Venus, and shews the Earth's annual motion round the Sun, its diurnal motion, and the Moon's motion round the Earth. The projection in the middle of the circular board M, consists of the following parts: a steel wire *a*, whose lower end is screwed to a bridge under the board, and which carries the Sun; over this is put a tube, on whose lower end a worm-wheel, worked by a worm on the arbor of the winch L above-mentioned, is fixed; and to the upper end the frame of wheels N, with the Earth and Moon. Over these is a conical tube, which has a flaunch at its lower end, and is fastened to the board M by three screws; the arms carrying the planets Mars F, Jupiter G, Saturn H, and the Herschel K, are fitted stiffly upon this tube, so as not to turn unless they are moved. These planets do not move by turning the winch, but are to be set by hand; as also their satellites. In the frame of wheels N (figs. 1 and 2) *g* is the first wheel; which is fixed to the wire *a* (fig. 1), and is without any motion: this works into another wheel *h* of the same size, fixed to the spindle *i*. The wheel *h* works another wheel *k* of the same size, on whose spindle *y* (fig. 1) the Earth is fixed. Besides the wheel *h*, the spindle *i* has three other wheels *l m n*, fixed on it. The wheel *l* turns *o*, which works a pinion beneath the wheel *g*, carrying the planet Mercury B (fig. 1): this pinion has a hollow spindle, and goes over the wire *a*. The wheel *m* on the spindle *i* works into *p*; which gives motion to the pinion *g* (whose spindle goes over the spindle of the pinion which carries Mercury), and has the planet Venus (D fig. 1) fixed to it. The large wheel *n* on the spindle *i* turns, by intermediate wheels, the pinion S, whose arbor goes over the spindle carrying the Earth: this has an arm for the Moon fixed to it. The wire *t*, to which the Moon is fixed, slides up and down through a hole in the end of the arm; and the lower end of the wire rests on a circular ring *v*, whose plane is parallel to the plane of the Moon's orbit; so that as the arm turns round, the wire is pushed up by the inclination of the ring, and falls by its own weight. Beneath this is a ring with divisions on it, shewing the Moon's age. When the winch L is turned, it works the worm-wheel beneath the board M, and moves the frame N (fig. 1) with the Earth round the Sun; and as the wheel *g* is fixed, the wheel *h* is turned by rolling round it; and as *k* (which it works) is of the same size with the other two, it turns the Earth so that its axis always points to the pole. The wheel *l*, by means of the wheel *o*, turns the pinion which carries Mercury B (fig. 1). The wheel *m* with the wheel *p* turns *g*, and the planet Venus D (fig. 1); and the wheel *n* turns the pinion *s*, and the Moon as before described. The number of teeth in the wheels and pinions respectively, must be so proportioned, that each planet may revolve in the same periods as we have described under ASTRONOMY.

PLANIMETRY, that part of geometry which considers lines and plane figures, without any regard to heights or depths. Planimetry is particularly restricted to the mensuration of planes and other surfaces; as contradistinguished from stereometry, or the mensuration of solids, or capacities of length, breadth, and depth. Planimetry is formed by means of the squares of long measures, as square inches, square feet, square yards, &c. that is, by squares whose side is an inch, a foot, a yard, &c. So that the area or content of any surface is said to be found, when it is known how many such square inches, feet, yards, &c. it contains.

PLANISPHERE, signifies a projection of the sphere, and its various circles on a plane; in which sense maps, wherein are exhibited the meridians, and other circles of the sphere, are planispheres. See MAP, PROJECTION, &c.

PLANISPHERE, is more particularly used for an astronomical instrument used in observing the motions of the heavenly bodies. It consists of a projection of the celestial sphere upon a plane, representing the stars, constellations, &c. in their proper order; some being projected on the meridian, and others on the equator.

PLANTAGO, PLANTAIN; a genus of the monogynia order, in the tetrandria class of plants. The calyx is four-cleft; corolla four-cleft; border reflex; stamina very long; capsules two-celled, cut transversely. There are 38 species, of which the most noted are: 1. The common broad-leaved plantain, called weybread; 2. the great hoary plantain, or lamb's tongue; 3. the narrow-leaved plantain, or ribwort; and the following varieties have also been found in England, which are accidental; the besom-plantain and rose-plantain. The plantains grow naturally in pastures in most parts of England, and are frequently very troublesome weeds. The common plantain and ribwort-plantain are both used in medicine, and are so well known as to need no description. They are said to be slightly astringent; and the green leaves are commonly applied to fresh wounds by the common people.

Of the coronopus, or buck's-horn plantain,

2

there are two varieties growing in England, viz. the common buck's-horn, which grows plentifully on heaths every where; and the narrow-leaved Welsh sort, which is found upon many of the Welsh mountains. The first of these was formerly cultivated as a salad herb in gardens, but has been long banished for its rank disagreeable flavour; it is sometimes used in medicine.

PLANTING, in agriculture and gardening. The first thing in planting is to prepare the ground before the trees or plants are taken out of the earth, that they may remain out of the ground as short a time as possible, and the next is to take up the trees or plants in order to their being transplanted. In taking up the trees, carefully dig away the earth round the roots, so as to come at their several parts to cut them off; for if they are torn out of the ground without care, the roots will be broken and bruised to the great injury of the trees. When you have taken them up, the next thing is to prepare them for planting by pruning the roots and heads. And first, prune off all the bruised or broken roots, all such as are irregular, and cross each other, and all downright roots, especially in fruit-trees; shorten the larger roots in proportion to the age, the strength, and nature of the tree: observing that the walnut, mulberry, and some other tender-rooted kinds, should not be pruned so close as the more hardy sorts of fruit and forest-trees; in young fruit-trees, such as pears, apples, plumbs, peaches, &c. that are one year old from the time of their budding or grafting, the roots may be left only about eight or nine inches long; but in older trees they must be left of a much greater length: but this is only to be understood of the larger roots; for the small ones must be chiefly cut quite out, or pruned very short. The next thing is the pruning of their heads, which must be differently performed in different trees; and the design of the trees must also be considered: thus, if they are designed for walls or espaliers, it is best to plant them with the greatest part of their heads, which should remain on till they begin to shoot in the spring, when they must be cut down to five or six eyes, at the same time taking care not to disturb the roots. But if the trees are designed for standards, you should prune off all the small branches close to the place where they are produced, as also the irregular ones which cross each other; and after having displaced these branches, you should also cut off all such parts of branches, as have by any accident been broken or wounded; but by no means cut off the main leading shoots which are necessary to attract from the root, and thus promote the growth of the tree. Having thus prepared the trees for planting, you must now proceed to place them in the earth; but if the first trees have been long out of the ground, so that the fibres of the roots are dried, place them eight or ten hours in water before they are planted, with their heads erect, and the roots only immersed in it; which will swell the dried vessels of the roots, and prepare them to imbibe nourishment from the earth. In planting them, great regard should be had to the nature of the soil; for if that is cold and moist, the trees should be planted very shallow; and if it is a hard rock or gravel, it will be better to raise a hill of earth where each tree is to be planted, than to dig into the rock or gravel, and fill it up with earth, as is too often practised, by which means the trees are planted as in a tub, and have but little room to extend their roots. The next thing to be observed is, to place the trees in the hole in such a manner, that the roots may be about the same depth in the ground, as before they were taken up; then break the earth fine with a spade, and scatter it into the hole, so that it may fall in between every root, that there may be no hollowness in the earth. Having filled up the whole, gently tread down the earth with your feet, but do not make it too hard; which is a great fault, especially if the ground is strong or wet. Having thus planted the trees, they should be fastened to stakes driven into the ground, to prevent their being displaced by the wind, and some mulch laid about the surface of the ground about their roots: as to such as are planted against walls, their roots should be placed about a foot from the wall, to which their heads should be nailed to prevent their being blown up by the wind. The seasons for planting are various, according to the different sorts of trees, or the soil in which they are planted; for the trees whose leaves fall off in winter, the best time is the beginning of October, provided the soil is dry; but if it is a very wet soil, it is better to defer it till the latter end of February, or the beginning of March; and for many kinds of evergreens, the beginning of April is by far the best season; though they may be safely removed at Midsummer, provided they are not to be carried very far; but you should always make choice of a cloudy wet season.

PLANTS, *physiology of*. The constituent or elementary principles of vegetables in general, are hydrogen, oxygen, and charcoal. These, as far as our observations have hitherto extended, are common to all vegetables. There are some other substances, such as lime, potass, iron, and azote, which are occasionally found in vegetables; but as they are not common to all plants, they cannot be considered as essential to the constitution of vegetable matter.

The parts of vegetables which naturalists are accustomed to consider as distinct in their nature and functions, are six: the stem or trunk, the root, the leaf, the flower, the fruit, and the seed. In many vegetables the root appears nearly similar, in all its constituent parts and principles, to the stem or trunk, and indeed the one seems a continuation of the other; which must be our apology for reversing in some degree the order of nature, and treating first of that part; which, though it seems to proceed or spring immediately from the other, is yet the most perfect in its organization, and is in general of the greatest use and importance to man.

I. The stem or trunk, which includes also the branches, we might say all the more solid and substantial parts of a tree or plant, consists of three parts, the bark, the wood, and the pith.

1st. The bark is protected on the outside by a cuticle, epidermis, or scarf-skin, which consists sometimes of numerous layers, and differs in thickness in different plants. This skin or cuticle is an organized body, composed of very minute bladders, interspersed with longitudinal fibres, as in the nettle, thistle, and the generality of herbs. It contains also longitudinal vessels, and is visibly porous in some plants, and particularly the cane.

2. On removing the cuticle, the true bark appears, and may be considered as a congeries of pulp or cellular substance, in which are placed a number of vessels, as well as longitudinal fibres. The vessels of the bark are differently situated, and destined for various uses, in different plants. In the bark of the pine, for instance, the inmost are lymph-ducts, exceedingly minute; those nearest the surface are gum or resiniferous vessels, for the secretion of the turpentine, and these are so large as to be visible to the naked eye.

3d. The wood lies between the bark and the pith. Its substance is denser than that of the bark, and its structure more difficult to be understood. It is however generally supposed to consist of two substances, the parenchymatous or cellular, and the ligneous. The ligneous parts are no more than a congeries of old dried lymph-ducts. Between the bark and the wood a new ring of these ducts is formed every year, which gradually loses its softness as the cold season approaches, and towards the middle of winter is condensed into a solid ring of wood. These annual rings, which are visible in most trees when cut transversely, serve as marks to determine their age. They seem to decrease in breadth, as the tree advances in age; and as they are found to be very unequal in size throughout, their breadth probably varies according as the season is favourable or otherwise.

Dr. Darwin distinguishes the wood into two parts, the sap-wood or alburnum, and the heart. The former is much less durable, and is most abundant in thriving trees. In an oak-tree the division between these parts is very distinguishable. The alburnum is gradually converted into heart; but we do not recollect to have met with any observations which determine the number of years in which this conversion takes place.

Dr. Darwin attributes to the sap-wood the office of nourishing the embryon buds.

"We may conclude," says this author, "that the umbilical vessels of the new bud are formed along with a reservoir of nutritious aliment about midsummer in the bark, which constitutes the long caudex of the parent bud, in the same manner as a reservoir of nutritious matter is formed in the root or broad caudex of the turnip or onion, for the nourishment of the rising stem; and that these umbilical vessels of the embryon bud, and the reservoir of nutriment laid up for it, which is secreted by the glands of the parent bud, and now intermixed with the present bark of the tree, become gradually changed into alburnum, or sap-wood, as the season advances, in part even before the end of the summer, and entirely during the winter months.

"That the alburnum of trees, which exists beneath the bark both of the trunk and roots of them, contains the nutritious matter deposited by the mature leaves, or parent buds, for the use of the embryon buds, appears not only from the saccharine liquor which oozes from the wounds made in the vernal months through the bark into the alburnum of the birch and maple, betula et acer; but also from the following experiment, which was conducted in the winter, before the vernal sap-juice rises.

"Part of a branch of an oak tree in January was cut off, and divided carefully into three parts; the bark, the alburnum, and the heart. These were shaved or rasped, and separately boiled for a time in water, and then set in a warm room to ferment; and it was seen that the decoction of the alburnum or sap-wood passed into rapid fermentation, and became at length acetous, but not either of the other, which evinces the existence both of sugar and mucilage in the alburnum during the winter months; since a modern French chemist has shewn by experiments, that sugar alone will not pass into the vinous fermentation, but that a mixture of mucilage is also required; and from this experiment it may be concluded, that in years of scarcity the sap-wood of those trees which are not acrid to the taste, might afford nutriment by the preparation of being rasped to powder, and made into bread by a mixture of flour, or by extracting their sugar and mucilage by boiling water. These observations have been since confirmed by the very accurate experiments of Mr. Knight, who has shewn that all the saccharine matter of fruit trees is elaborated in the leaves of the preceding year, and deposited in the alburnum, whence it is drawn in the following spring for the perfecting of the flower and the fruit. An essential caution (by the way) to unskilful pruners (such as the bulk of common gardeners are), who in cutting off the new wood, or alburnum, in the spring, just cut off so much of the fruit (see PRUNING); and when gardeners (falsely so called) pull off the leaves of vines, and other fruit-trees, they destroy the crop of the succeeding year.

One striking difference between the wood and the bark is, that the former is possessed of spiral vessels which run from one end of the tree to the other. From the great resemblance of these vessels to the air-vessels of insects, they are supposed to be subservient to the same function. The stem of some plants is entirely hollow; partly, it is supposed, from these plants, which are generally of a quick growth, requiring a more than ordinary supply of air.

Dr. Darwin considers the spiral vessels above alluded to as lymphatics. He admits that air is observed to issue both from green and dry wood cut transversely, which is distinctly seen by plunging the wood in water, and removing the pressure of the atmosphere by the air-pump. This circumstance, however, he attributes to the rigidity of the fibres of wood, which, when divided, suffer the sap to escape, when, as the vessels cannot collapse, the air consequently enters in its place. He illustrates and confirms his opinion with his accustomed ingenuity, and among other observations relates the following experiment; "I placed, in the summer of 1781, some twigs of a fig-tree with leaves on them, about an inch deep in a decoction of madder, and others in a decoction of log-wood, along with some sprigs cut off from a plant of picris. These plants were chosen because their blood is white. After some hours, on the next day, on taking out either of these, and cutting off from its bottom about an eighth of an inch of the stalk, an internal circle of red points appeared, which I believed to be the ends of absorbent vessels coloured red with the decoction, and which probably existed in the newly-formed alburnum, or sap-wood; while an external ring of arteries was seen to bleed out hastily a milky juice, and at once evinced both the absorbent and arterial system.

Dr. Darwin admits the existence of air-vessels which pass through the bark to the sap-wood; but these run transversely, and not in the direction of the trunk or arms. Du Hamel likewise observed large vessels, some round and some oval, which in the birch-tree stand prominent, and pierce the outer bark.

4th. The pith is situated in the centre of the stem, and in young plants it is very abundant. It is said by some authors to consist of exactly the same substance as the parenchyma or cellular substance of the bark; and to be composed of small cells or bladders, generally of a circular figure, though in some plants, as the borage and thistle, they are angular. In most plants the pith gradually dies away as they approach to maturity; and in old trees it is almost entirely obliterated. The pith appears to be essential to the life of the other parts in young shoots. In those plants which have hollow stems, this central cavity, though not filled with the pith or medulla, appears to be lined with it.

Such are the solid parts of plants; but to render their organization more clearly understood, in Plate Miscel. fig. 186, is the section of a branch of ash cut transversely, as it appears to the eye. Fig. 187, is the same section magnified: AA the bark; BB an arched ring of sap-vessels next the cuticle; CCC the cellular substance of the bark, with another arched row of sap-vessels; DD a circular line of lymph-ducts next the wood; EE the wood; F the first year's growth; G the second; H the third; HI the true wood; KK the great air-vessels; LL the lesser air-vessels; N the pith.

There is reason to believe that the proper entrance of the air to plants, is through the cuticle; which is proved to be a vascular substance, since, when under an exhausted receiver, it issues directly through the cuticle. That the air is necessary to the sustenance of plants, appears from the experiments of Dr. Bell. In the winter season he covered several young trees with varnish, leaving the tops of the branches only exposed to the air. They remained in this situation during the following summer, when some of them lived, though in a languid state; but those from which the air had been more accurately excluded, died without a single exception. To this proof the same author adds, that trees overgrown with moss have few leaves, weak shoots, and scarcely any fruit; and that it is the common practice of all judicious gardeners to strip the moss from the bark of aged trees, which by admitting the air generally restores them to vigour and fruitfulness.

II. The root, which fixes the plant to the earth, and is the chief source of its nourishment, differs much in different species of vegetables. All roots agree in being fibrous at their extremities, and it is by their fibres chiefly that they are fitted to draw nourishment from the earth. The internal structure of the root, or rather of its fibres, differs not very materially in general from that of the stem. It consists of a cuticle, bark, wood, and commonly of a small portion of pith; though there are some roots which have no pith at all; while there are others which have little or none at the extremities, but a considerable quantity near the trunk. The cuticle, in all roots, at a certain age, is double; the cortical substance, or bark, differs greatly in its quantity and disposition in different plants. The roots, as well as the trunk of plants, are furnished with a variety of vessels for the purpose of conveying and circulating air and the juices necessary to their nourishment.

In fig. 188. is a section of the root of wormwood, as it appears to the eye; and fig. 189. is the same magnified. AA, the skin with its vessels; BB, the bark; CCC, the lymph-ducts of the bark; the other holes are small cells or sap-vessels. DDD, parenchymatous insertions from the bark; EEE, the rays of the wood, with the air-vessels. This root has no pith.

III. The leaves are organs essential to the existence of plants. Trees perish when totally divested of them; and in general, when stript of any considerable proportion of their leaves, they do not shoot vigorously. The leaves exhibit a beautiful appearance when the intermediate parenchymatous matter is consumed by putrefaction. Both surfaces of the leaf are covered with a membrane, which is a thin bark, continued from the scarf-skin of the stalk.

IV. The flower consists of four parts, the calyx, the corolla, the stamina, and the pistillum. The calyx or flower-cup is almost always of a green colour, and is that which surrounds and supports all the other parts of the flower. The corolla is of various colours, is variously shaped in different vegetables, and is that which constitutes the most conspicuous part of the flower. It sometimes consists of one continued substance, but more frequently of several portions, which are called petals. The stamina are supposed to be the male part of the flower. Linnæus defines them to be an entrail of the plant, designed for the preparation of the pollen. Each stamen consists of two parts; the filamentum or fine thread which supports the anthera, and the anthera itself, which contains within it the pollen, and when come to maturity bursts and discharges it for the impregnation of the germen. From the supposed function of the stamina, they afford the chief foundation of the distribution of the vegetable system into classes. Such flowers as want this part are called female; such as have it, but want the pistillum, are male; such as have them both, hermaphrodite; and such as have neither, neuter.

The pistillum or pointal is supposed to be the female pa.t of the flower; it is defined by Linnæus to be an entrail of the plant, designed for the reception of the pollen. It consists of three parts, the germen, the style, and the stigma. The germen is the rudiment of the fruit accompanying the flower, but not yet arrived at maturity. The style is the part which serves to elevate the stigma from the germen. The stigma is the summit of the pistillum, and is covered with a moisture for the breaking of the pollen. See BOTANY.

The pericarpium or seed-vessel is the germen grown to maturity. Such are the constituent parts of the flower; they are however infinitely varied, and serve both to diversify the face of nature, and to interest and delight the curiosity of man. One curious fact it is necessary to notice, before we dismiss this branch of the subject, and that is, that in the perennial plants especially, every flower is perfectly formed many months before it makes its appearance. Thus the flowers which appear in this year are not properly the productions of this year; the mezereon flowers in January, but the flowers are completely formed in the bud in the preceding autumn: the same is obvious in the kalmir and rhododendron. If the coats of the tulip-root also are carefully separated about the beginning of September, the nascent flower, which is to appear in the following spring, will be found in a small cell, formed by the innermost coats, as represented in plate fig. 190, where the young flower A appears towards the bottom of the root.

V. The fruit consists of nearly the same parts as are found in the stem; of a skin or cuticle, which is a production or continuation of the skin of the bark; and of an outer parenchyma, which is the same substance continued from the bark, only that its vesicles are larger and more succulent or juicy. Next the core there is commonly an inner pulp or parenchyma; and the core is no more than a hard woody membrane, which incloses the seed. It is to be observed, however, that the organization of fruit is very various; in some the seeds are dispersed through the parenchymatous or pulpy substance; in some, instead of a core, we find a strong woody substance, inclosing the seed or kernel, which from its great hardness is termed the stone; in some, there are a number of seeds; and in others, only a single seed, inclosed in a large mass of parenchymatous matter.

VI. The seed is a deciduous part of a vegetable, containing the rudiment of a new one. The essence of the seed consists in the corculum or little heart, which is fastened to the cotyledones or lobes, and involved in them, and closely covered by its proper tunic. The corculum consists in the plumula, which is the vital speck of the future plant, extremely small in its dimensions, but increasing like a bud to infinity. The rostellum, however, must be included, which is the base of the plumula; it descends and strikes root, and is the part of the seed originally contiguous to the mother-plant. It is commonly supposed, and with some reason, that the perfect plant, or at least all the organization which is requisite to a perfect plant, exists in the seed surrounded by a quantity of farinaceous matter, which serves to absorb moisture, and to furnish nourishment to the corculum till its parts are sufficiently unfolded to draw support from the soil. A kidney-bean, or lupin, when it has been soaked for some time in water, and begun to swell, is easily separated into its two lobes; and between these is displayed the nascent plant. The naked eye can easily discern the stem, and its connection with the lobes. Through the lobes are diffused innumerable vessels, which immediately communicate with the embryo plant. On the external surface of the seed are absorbent vessels, which attract the moisture; by this moisture a degree of fermentation is produced; and thus a juice is prepared by a natural process, in every respect proper for the nourishment of the plant in its first efforts to extend its tender frame. The plant in its infancy is almost a gelatinous substance, and increases and indurates by degrees: and in general the hardness of wood bears a pretty exact proportion to the slowness with which a plant increases. That part of the stem which is next the root is the first which assumes the woody texture.

M. Bonnet, in order to ascertain how far the lobes of the seed were necessary to the growth and health of the corculum, detached them with great dexterity without a vital injury to the infant plant. Some French beans treated in this manner, and sowed in a light soil, grew; but the consequence was, that not only the first leaves were much smaller, but the plants were uniformly weaker in every part of their growth than others, which for the sake of comparison were sown at the same time without being mutilated. The plants from the seeds which were deprived of the lobes put forth fewer blossoms, and produced less seed. The seeds of mosses are naturally devoid of lobes. The first leaves which make their apppearance, and which are called seminal, appear not less necessary to the perfection of the plant than the farinaceous lobes. If they happen to be broken off, the plant experiences a proportional loss of vigour.

It is matter of curious observation, that seed, thrown into the ground at random, should always come up in the proper direction. M. Dodart has offered an ingenious explanation of this fact, which consists in suppoing that the rostellum contracts by humidity, and that the plumula on the contrary contracts by dryness. According to this idea, when a seed is put into the ground the wrong way, the rostellum, which then points upwards, contracts itself towards the part where there is most humidity, and therefore turns downwards. The plumula on the contrary pointing downwards, turns itself towards the part of the soil which is driest, and therefore rises towards the surface. This explanation, however, evidently rests on no better basis than conjecture; the experiments in which the truly philosophical Mr. Knight is now engaged, will probably decide the question.

Independant of the seed, there are two other methods by which plants are propagated, by slips and suckers; and many plants naturally make an effort to propagate themselves in this manner. The bulbous-rooted plants in general increase by offsets. When a tulip is first planted in the spring, the stem issues from the inner part of the bulbous root; but when the tulip is taken up in the autumn, the stem no longer proceeds from that part of the root, but seems attached to one side. The fact is, that the root which is taken up is only a part of that which was planted. Some of the outer layers of the original root have decayed, by having the substance absorbed for the nourishment of the blossom, and from the remainder what may be termed a new root has been provided for the future year.

Besides the parts above-mentioned, some writers have treated of the nerves and muscles of vegetables. These, it is confessed, have never been demonstrated, but their existence has been inferred from the motions of peculiar parts of vegetables, and more particularly those of the flower. The greater number of plants close, either partly or entirely, their petals towards night, or on the approach of cold or wet weather. The hedysarum gyrans whirls its leaves in various directions, when the air is still, by an apparently voluntary effort. The dionæa muscipula, Venus's fly-trap, closes its leaves from the stimulus of insects which crawl upon them, and pierces them with its prickles. The phenomena of the common sensitive plant, the most distant branches of which close their leaves on any violence being offered to any part of it, are commonly known and admired. Whether these appearances are the consequences of sensation in the vegetable, it is impossible to determine; but they are so similar to what we observe in animated beings, that the term sensitive plant is very appropriate. If the distant parts of the plant are affected through the medium of nerves, their action seems to be much less quick than those of animals, as the half or the whole of a minute generally elapses in this climate before the whole of the plant droops, but it is said to be otherwise in their native climate.

Fluids of plants. As the true course of the fluids in animals, and the power by which the circulation is performed, are modern discoveries, so we have still to learn a satisfactory explanation of the corresponding circumstances in vegetable life. That the juices of plants pass from one part to another, admits of no doubt; but the observations of naturalists have been so various and inconsistent, that no theory can be framed sufficiently comprehensive to embrace their several conclusions. It may indeed be concluded, that as the life of a vegetable is more obscure, so we cannot expect the same energy of action which is manifested in the circulating organs of animals.

It is manifest to common observation, that there does not exist the same intimate union between the different parts of a vegetable as we find between those of animals: different parts of the same plant will put forth leaves and ripen fruit at very different seasons of the year, according to the particular temperature in which each branch is placed. A branch of a vine introduced into a hot-house will vegetate in the midst of winter; while the rest of the plant, which remains exposed to the vicissitudes of the climate, will evince little or no sympathy. We know of nothing like this in the animal kingdom, and therefore it seems reasonable to conclude that there is not in a vegetable any thing analogous to a heart, from and to which, as a common centre, its fluids are directed.

It has been assumed by many botanists, that there is a succus communis, or universal sap, differing little from water, and the same in all plants. It seems more consonant, however, to observation, to conclude that the fluids differ in different genera of vegetables. There is an infinite variety in the obvious properties of the juices of plants, some of which, in tead of resembling water, are more of the consistency of milk. Grafts only grow on kindred stocks, which may reasonably be attributed to an unfitness of the juices of other genera of plants.

With respect to what has been called the succus proprius of plants, which alone has been said to differ in different plants, it seems to be nothing more than the product of a process analogous to that of secretion in animals; thus a plant of mint nourished by water alone, will still elaborate, by its vegetative power, an essential oil peculiar in odour to its own species.

The juices of many plants abound so much in a mucilaginous and saccharine principle as to be fermentable. The sap of the birch-tree drawn in spring by tapping has been long employed to make wine. A species of the maple affords sugar; but no plant abounds so much in this vegetable product as the sugar-cane. The mucilaginous or gummy principle prevails more particularly in the different sorts of plum. By the experiment on the sap-wood of the oak, related above, it appears that there are both sugar and mucilage in the juices of a tree remarkable for its bitterness.

Mucilage and sugar seem to exist diffused in the general mass of fluids in vegetables; on the other hand, turpentine, resin, expressed and essential oil, and what is called the extractive principle, seem to be the product of secretion; but the fluids deposited in cists are so often necessarily mixed with the other juices, by the processes of extraction, that there must remain considerable doubt as to the accuracy of this particular distribution. It may generally be remarked, that the products of secretion in plants are of an inflammable nature. The seeds of plants generally abound in a heavy oil which may be obtained by pressure, such as oil of almonds, linseed, and palma christi or castor oil. The essential oils, or those obtained by distillation, are in general extremely acrid; so much so, that they produce a wound when inadvertently applied to the tongue in an undiluted state. Oil of cloves is employed to destroy the exposed nerve in decaying teeth, in order to cure the tooth-ache; but its use requires considerable caution, as it is liable to injure the teeth adjoining to that which is diseased. The bitter, narcotic, and acid principles, are also to be considered as the products of secretion.

Few questions have excited greater attention than those respecting the course of the fluids in vegetables. When wounds have been made in trees, it is found that the sap flows more copiously from the upper side, or that part of the wound which is nearest the branches. From whatever cause this may proceed, it seems to be intimately united with another fact. If a wound is made through the bark of a growing tree, the effort which takes place to heal the wound is made from above. The lower lip of the wound remains shrivelled and inactive; and if the wound has been extensive, seems from year to year rather to suffer decay; the upper lip, on the contrary, becomes turgid, and extends itself downwards to repair the breach. This effort is particularly remarkable in wood which has suffered compression from the embraces of the honeysuckle. Dr. Darwin, in his Phytologia, attempts to explain this and many other phenomena by the ingenious idea, that a tree is a complex being composed of many individuals; for he considers every bud of a tree as having an independant vegetative power. The effort above-mentioned he considers as caused by the buds of the tree sending down their vessels, and propelling their fluids towards the root. Yet it seems generally to have been concluded, that the sap rises upwards in the spring from the root towards the branches. Early in the season Dr. Hope made incisions of different altitudes into the root and stem of a birch. As the sap rose, it first flowed from the superior margin of the lowest incision, and then irregular succession, from the upper margins of the other incisions, till at last it reached the highest. It does not appear, however, to be satisfactorily ascertained whether the sap in this experiment proceeded from the root, or whether it was successively put in motion higher and higher as the process of vegetation took place; for the upper parts of a tree are more exposed to cold, and vegetation may on that account be retarded. Dr. Hales cut off the stems of vines in the spring, and then by fixing tubes on the stumps, was able to ascertain with what force the sap was propelled. In some trials the sap rose to the height of 35 feet. Tubes have been fixed to the large arteries of animals, as near as possible to the heart, in which the blood did not rise higher than nine feet.

Such being the force with which the juices of vegetables are propelled, it can scarcely be doubted that their sap is contained in vessels. Yet differences of opinion have arisen even as to this particular; and as the vessels of vegetables have not been satisfactorily traced, it has been advanced that there exists no other circulation than a transmission of fluids through cellular substance. A circulation, however, so vigorous as that of a thriving vegetable, cannot be conceived to be conducted, except through a limited and well defined channel. It must be confessed, that considerable difficulties attend this inquiry; but the existence of vessels, at least in the leaves of plants, is proved by the following simple experiment, which may be satisfactorily tried on plants having coloured sap: Tear asunder a fig-leaf, for instance, and the white fluid will be observed to flow from certain points which are doubtless the extremities of broken vessels.

From the experiments of Dr. Hales abovementioned it appears, that the sap of the vine rose in a tube to 35 feet, or about the same height as a column of water equal in weight to the atmosphere. The pressure of the atmosphere is known to assist animals in sucking; and whether some modification of the same power may not assist vegetable absorption, may be the subject of future inquiry.

Dr. Hales, in his statical experiments, mentions several, in which he tried to change the natural flavour of fruits, and to communicate those of several spirituous liquors, and of different odoriferous infusions. With this intention he plunged in different liquors branches loaded with fruit, and left them there for some time, without being able to perceive that the taste of the fruits was in the least altered, whether the experiment was made upon them ripe or unripe. But he almost always perceived the smell of the liquors or infusions in the stalks of the leaves, and in the wood. He conjectures, with much probability, that the vessels near the fruit become so fine as not to admit the odoriferous particles.

M. Bonnet made experiments on flowers similar to those which Dr. Hales made on fruits. He chose such flowers as have naturally little perfume, as the different species of French beans. Stems with these flowers were immersed in tubes, some of which were filled with spirit of wine, others with Hungary water, &c. In about 24 hours the flowers were faded, and they had already acquired in a very sensible degree the odours of the liquors which they had imbibed. The odour became much more remarkable a few days afterwards. M. Bonnet also found that the leaves of the apricot-tree acquired a sensible odour from the liquors into which branches of that tree were plunged.

Functions of plants. The leaves of plants have been not improperly compared with the lungs of animals. "Plants, as well as animals," says an author whom we have already quoted with approbation, "perspire, and in both cases this function is essential to health. By the experiments of Dr. Hales and M. Guettard, it appears that the perspirable matter of vegetables differs in no respect from pure water, excepting that it becomes rather sooner putrid. The quantity perspired varies, according to the extent of the surface from which it is emitted, the temperature of the air, the time of the day, and the humidity of the atmosphere. As the leaves form the greatest part of the surface, it is natural to suppose, that the quantity of these will very materially affect the quantity of the perspiration. Accordingly, the experiments of Dr. Hales have ascertained, that the perspiration of vegetables is increased or diminished, chiefly in proportion to the increase or diminution of their foliage. The degree of heat in which the plant was kept, according to the same author, varied the quantity of matter perspired; this being greater, in proportion to the greater heat of the surrounding atmosphere. The degree of light has likewise considerable influence in this respect; for Mr. Philip Miller's experiments prove, that plants uniformly perspire most in the forenoon, though the temperature of the air in which they are placed should be unvaried. M. Guettard likewise informs us, that a plant exposed to the rays of the sun has its perspiration increased to a much greater degree, than if it had been exposed to the same heat under the shade. Finally, the perspiration of vegetables is increased in proportion as the atmosphere is dry, or in other words, diminished in proportion as the atmosphere is humid."

Dr. Hales found that a sun-flower, weighing three pounds, perspired 22 ounces during 24 hours. Dr. Keil perspired 31 ounces in 24 hours. The quantity therefore perspired by the sun-flower was much greater, in proportion to its weight, than that perspired from the human body. Dr. Keil ate and drank four pounds ten ounces in 24 hours. Seventeen times more nourishment was taken in by the root of the sun-flower, than was taken in by the man. If the perspiration of vegetables is checked, they speedily fade. It is checked from glutinous substances adhering to their surface: hence the advantage of washing them. The more healthy and vigorous the plant, the more copious the perspiration; though an excess, as well as a defect of it, seems prejudicial and even destructive to vegetables. It bears also a proportion to the quantity of leaves, these being the principal organs of perspiration.

The odoriferous exhalation of leaves and flowers forms an atmosphere round vegetables, which strikes our senses, and which the contact of a body on fire is sometimes capable of inflaming, as has been observed with regard to the fraxinella.

The experiments of Dr. Priestley have sufficiently shewn that vegetables have the power of correcting bad air; and Dr. Ingenhouz has proved that they have the faculty of producing oxygen gas, only when acted on by the rays of light. If a vegetable is immersed in water, and the rays of the sun directed on it, air-bubbles will be observed to collect on the leaves, and at length rise to the surface of the water. This appearance is most remarkable in the morning, as the leaves have not then been previously exhausted by the action of light. Oxygen air of a great degree of purity may be obtained in the summer time, by inverting a jar filled with water in such a manner as to receive the air-bubbles as they arise. All plants, however, do not emit this air with the same facility; there are some which emit it the moment the rays of the sun act upon them, and this is the case with lavender. Some aquatic plants afford oxygen air with great facility, some more slowly, but none later than eight or ten minutes, provided the sun's light is strong. The air is almost entirely furnished by the inferior surface of the leaves of trees; herbaceous plants afford it from almost the whole of their surface. The leaves afford more air when attached to the plant, than when gathered; and the quantity is greater, the fresher and sounder they are. Young leaves afford but a small quantity of oxygen air; those which are full grown afford more, and the more the greener they are. The epidermis, the bark, and petals, do not afford it, and in general oxygen proceeds only from those parts of plants which are of a green colour. Thus green corn and green fruits afford this air, but it is not produced by those which are ripe; and flowers in general render the air noxious. These facts may serve to explain the manner in which the light of the sun operates in maturing fruits, viz. by expelling the superfluous oxygen, and thus changing them from a harsh and sour, into a mild and sweet substance. Aquatic plants, and such as grow in moist places, are remarkable not only for affording a large quantity of oxygen gas, but also for absorbing hydrogen gas, and are therefore in all respects calculated for purifying the air of marshy situations. A very extraordinary power of absorbing hydrogen air was observed in the willow by Dr. Priestley; and this fact seems connected with the rapid growth of that plant in marshy situations, where much of this air is produced. M. Sennabier found that plants yield much more oxygen air in distilled water impregnated with carbonic acid gas, than in simple distilled water.

It appears further, from the experiments of Dr. Priestley, that plants will bear a greater proportion of hydrogen than of carbonic acid air, and that oxygen gas appeared generally injurious to plants. A sprig of mint growing in water, placed over a fermenting liquor, and of course exposed to carbonic acid air, became quite dead in one day; a red rose became of a purple colour in 24 hours. Plants die very soon both in nitrous air, and in common air when saturated with it. Air appears uniformly to have been purified by healthy plants vegetating in it; but these experiments require great nicety, as the least degree of putrefaction will injure the air. The air contained in the bladders of marine plants was found considerably purer than common air.

Atmospheric air is restored, after being injured by respiration or combustion, by a plant vegetating in it. This restoration of air depends upon the vegetating state of the plant; for a number of mint-leaves fresh-gathered being kept in air in which candles had burnt out, did not restore the air. Any plant will effect this purpose, but those of the quickest growth in the most expeditious manner.

That plants have a property of producing pure air from water, is evident from an experiment of Dr. Priestley's. The green matter which is to be observed in water is doubtless a vegetable production. Water containing this green matter always afforded oxygen air in a large quantity; but water which had it not afforded none. It has been frequently observed that vegetables do not thrive in the dark. A receiver was therefore filled with water, and kept till it was in a state of giving air copiously; after this it was removed into a dark room, and from that time the production of air entirely ceased. When placed again in the sun, it afforded no air till about ten days after, when it had more green matter; the former plants being probably all dead, and no air could be produced till new ones were formed.

From various experiments it appeared that different animal and vegetable putrescent substances afforded a very copious pabulum for this green vegetable matter, which produced so freely the oxygen air; whence the philosophic author of this discovery is led to the following conclusions: "It is impossible," says he, "not to observe from these experiments the admirable provision in nature, to prevent or lessen the fatal effects of putrefaction; especially in hot countries, where the rays of the sun are most direct, and the heat most intense. Animal and vegetable substances, by simply putrefying, would necessarily taint great masses of air, and render it unfit for respiration, did not the same substances, putrefying in water, supply a most abundant pabulum for this wonderful vegetable substance, the seeds of which seem to exist throughout the atmosphere. By these means, instead of the atmosphere being corrupted, a large quantity of the purest air is continually thrown into it. By the same means also, stagnant waters are rendered much less offensive and unwholesome than they would otherwise be. That froth which we observe on the surface of such waters, and which is apt to excite disgust, generally consists of the purest air, supplied by aquatic plants. When the sun shines, this air may be observed to issue from them. Even when animal and vegetable substances putrefy in air, as they have generally some moisture in them, various other vegetable productions, in the form of mold, &c. find a proper nutriment in them, and by converting a considerable part of the noxious effluvia into their own substance, arrest it in its progress to corrupt the atmosphere."

The same vegetables which afford oxygen

air very plentifully in the light of the sun, afford in the shade air less pure than that of the atmosphere. This striking effect of light on vegetables is a strong argument in favour of the opinion, that the motion of the juices of vegetables is performed by vessels, which, like those of animals, possess irritability, and are excited to action by stimulating substances.

The effect of vegetation in producing the oxygen air which was afforded in the preceding experiments, seemed in some measure dubious to count Rumford, who extracted vital air by immersing in water a variety of substances, as raw silk, cotton, wool, eiderdown, hare's fur, sheep's wool, ravellings of linen, and human hair. He was led, from the result of these trials, to suspect that the pure air was merely separated from the water; and that any substance which would act by a capillary attraction, so as to separate the component parts of the water, would effect the production of pure air. He therefore procured a quantity of spun glass, which consists of minute tubes, and immersed it in water, but the quantity of pure air produced was very trifling. Hence he concludes, that there is something in those substances which operates in producing pure air, and that it is not merely a mechanical separation of the component parts of water.

The light of lamps produced the same effect as the sun's light; air in great quantities was produced, and perfectly pure. Vegetables will also, with any strong light, produce oxygen air as well as with the light of the sun. The air from silk was much superior to that from vegetables.

Plants have a remarkable sensibility to light; they unfold their flowers to the sun, they follow his course by turning on their stems, and are closed as soon as he disappears. Vegetables placed in rooms where they receive light only in one direction, always extend themselves that way. If they receive light in two directions, they direct their course towards the strongest. Trees growing in thick forests, where they only receive light from above, direct their shoots almost invariably upwards, and therefore become much taller and less spreading than such as stand single. This affection for light seems to explain the upright growth of vegetables, a curious phenomenon, too common to be much attended to. It has been ascertained by repeated experiments, that the green colour of plants is entirely owing to light; for plants reared in the dark are well known to be perfectly white.

If we take a succulent plant, and express its juice, the liquor appears at first uniformly green; but allow it to stand, and the green colour separates from the watery fluid, and falls to the bottom in a sediment. If we collect this sediment it will be found to be of an oily nature, for it does not dissolve in water; but it will in spirit of wine, or oil, to which it imparts a green colour. As the sun produces the green colour in plants, and as this resides in an oily matter, it was formerly concluded that light produces the oily matter of vegetables, and that it effects this by furnishing the principle of inflammability. The new chemical doctrines, however, afford a much more satisfactory explanation of the effect of the sun's rays in producing the oily matter in vegetables. Vegetable matter consists in general of carbon, hydrogen, and oxygen; the sun's ray produce a disengagement of the latter principle in the form of vital air, and the two former are the constituent principles of oil.

M. Bonnet made a series of experiments in order to ascertain whether the superior or the inferior surfaces of leaves have a greater share in performing perspiration. From the trials which he made, he concludes that the inferior surface of the leaf is in general by far the most active in this respect, though in one or two species of vegetables this difference was much less remarkable. The mallow was the only vegetable the leaves of which perspired more by the upper than the inferior surface. The method which he employed to ascertain the comparative effect of the two surfaces was, to cover first one and then the other surface with oil. The leaves were then immersed in tubes filled with water, and the quantity of perspired matter was measured by the length of the tube emptied in a given time. The oil, by stopping up the pores, prevented perspiration from the surface to which it was applied. Some large leaves of the white mulberry-tree being kept suspended on water with their upper surfaces in contact with the fluid, faded in five days; some leaves of the same tree, being placed in a similar situation, but with the inferior surface touching the water, were preserved green for nearly six months.

The sexual system has been the prevalent system of botany for many years. It is well known that the palm is of that class of vegetables which has flowers of different sexes on different trees. The peasants in the Levant, whether acquainted with this fact, or whether directed to the practice by accident alone, have been accustomed to break branches from the male palm while in flower, and attach them to the female plant, which they find to be constantly productive of an abundant crop. This fact has also been proved by a most decisive experiment of M. Gleditsch. There was in the royal garden at Berlin a beautiful palm-tree, a female plant, which, however, though 25 years old, had been always barren. There was another palm at Leipsic of the male kind, which blossomed every year. The ingenious botanist undertook to fecundate the palm at Berlin from that at Leipsic, and had some of the blossoms conveyed by the post. The consequence was, that he produced that season excellent dates; and the experiment, prosecuted with some variation for several succeeding years, was attended with the same success.

It has been said, that the pollen was destined for the impregnation of the germen. This is performed in the following manner: The antheræ, which at the first opening of the flower are whole, burst soon after, and discharge the pollen. Being dispersed about the flower, part of the pollen lodges on the surface of the stigma, where it is detained by the moisture with which that part is covered. Each single grain or atom of the pollen has been observed by the microscrope to burst in this fluid, and is supposed to discharge something which impregnates the germen below. What the substance is which is so discharged, and whether it actually passes through the style into the germen, seem yet undetermined, from the great difficulty of observing such minute parts and operations. In some vegetables, the stamina move towards the pistillum; and a very evident motion of them is observed in the flowers of the common berberry, on touching them with the point of a pin.

As vegetables, like animals, are liable to decline, and ultimately to perish by age, the offices of the parts of fructification are of the most important nature. If trees had been capable of increase only by grafts, layers, or cuttings, it seems probable that they would long ago have been lost. An ingenious and philosophical botanist, Mr. Knight, has particularized several sorts of apples, which a century ago were extremely thriving and in high repute, some of which are at this time wholly lost, and others are in such a state of decline and imperfection as to be little esteemed. By the fertility of seeds, however, new varieties of this as well as of all other fruits and trees are continually produced. A tree produced from a cutting exactly resembles the parent plant; not so one raised from a seed, which generally derives its origin from more than one parent, and in dioecious plants must always do so. Hence the endless variety which interests the florist. When this cause is considered as having operated for ages, we cease to wonder at the diversified appearances which we observe in a bed of seedling plants. Mr. Knight strongly advises to take grafts from individuals lately raised from seeds, which he assures us possess a vigour of growth never met with in old varieties. Strawberries and potatoes also become unproductive, unless the old varieties are replaced by others raised from seed.

The nourishment of vegetables, as it is so intimately connected with the important science of agriculture, has deservedly attracted considerable attention. Mr. Boyle dried in an oven a quantity of earth proper for vegetation, and after carefully weighing it, planted in it the seed of a gourd; he watered it with pure rain-water, and it produced a plant which weighed fourteen pounds, though the earth had suffered no sensible diminution.

A willow-tree was planted by Van Helmont in a pot containing 100 pounds of earth. This was in general watered with distilled water, or sometimes with rain-water which appeared perfectly pure. The vessel containing the plant was covered in such a manner as totally to exclude the entrance of all solid matter. At the end of five years, upon taking out the plant, he found it to have increased in weight not less than 119 pounds, though the earth had lost only two ounces of its original weight.

These experiments would admit of some doubt, and must have remained in a great measure inexplicable, but for the experiments of Mr. Cavendish, and the facts related by Dr. Priestley, which place it beyond a doubt, that vegetables have a power of decomposing water, and converting it, with what they derive from the atmosphere, into almost all the different matters found to exist in their substance.

All the proper juices of vegetables depend on the organization, as it is evident from the operation of grafting. From the materials of simple water and air, are produced those wonderful diversities of peculiar juices and fruits, which the vegetable world affords; and the immense variety of tastes, smells, &c. In the same vegetable what a variety is found! The bark is different in taste from the wood, the peculiar juices have something different from them both, and the pith of some plants affords a matter which could not have been expected from their exterior qualities. The root is often different from the stem, and the fruit from both, in all their sensible qualities.

In whatever way the nourishment of vegetables is received, it may fairly be said to consist principally of water. We are inclined to believe, however, that calcareous earth, in small portions, may enter into the composition of at least many vegetables; since animals which exist entirely on vegetable food are found to have in their solid parts, the bones for instance, a considerable portion of this substance; though it must be confessed that chemical analysis, as far as it has hitherto gone, does not warrant us in supposing calcareous earth to be an essential constituent of all vegetable matter. It may be said further, that on some occasions the addition of other matters, as of different kinds of manure, adds greatly to the growth of vegetables; but in whatever degree a rich soil or dung may add to the luxuriance of growth, other facts seem to prove that it is not essential to vegetation. It is well known that many herbs flourish in pure water; and that pear, plum, and cherry-trees, planted in pure moss, have arrived at such perfection as to produce good fruit.

Different theories have been advanced to account for the operation of manures in promoting the growth of vegetables, none of which seem altogether satisfactory. The common opinion is, that the substances employed as manures contain those principles which constitute the food of plants, and which are absorbed by their roots. This hypothesis is doubtless true to a certain extent, especially when it is considered that carbon forms a great part of many manures. Another opinion is, that manures act by bringing soils to such a consistence as is favourable to the growth of the roots of vegetables, and to the affording of them water in a proper quantity. A third opinion is, that manures act as stimuli on the roots of vegetables, and thus excite them to more vigorous action. Some authors think that manures act as solvents on matters previously contained in the soil, and thus fit them for entering the roots of plants; and others, that they act chemically, by forming combinations which are favourable to vegetation. Which of these hypotheses is best founded, it is difficult to determine; but it does not seem unlikely that they may all have some foundation in fact.

When we attempt to discover the component principles of the objects around us, and the sources whence they were supported, we are lost in the greatness and diversity of the scenes presented to us. We see animals nourished by vegetables, vegetables apparently by the remains of animals, and fossils composed of the relics of both of these kingdoms. It seems certain, however, that vegetables preceded animals. A seed of moss lodging in a crevice of a bare rock is nourished by the atmosphere, and the moisture afforded by the rains and dews. It comes to perfection, and sheds its seeds in the mouldering remains of its own substance. Its offspring do the same, till a crust of vegetable mould is formed sufficiently thick for the support of grass and other vegetables of the same growth. The same process going forward, shrubs, and lastly the largest trees, may find a firm support on the once barren rock, and brave the efforts of the tempest.

From the advantages derived from a change of crops in agriculture, it has been supposed that different vegetables derive different kinds of nourishment from the same soil, selecting what is best adapted to their own support, and leaving a supply of nourishment of another kind for vegetables of another genus. Was this, however, the case, vegetables would not so much impede each other's growth when placed near together. And in the operation of grafting, we have a clear proof that the juices received by the root of one species of tree may, by the organization of the inserted twig, be subservient to the growth of leaves, flowers, and fruit, of a different kind. The advantage derived from a change of crops may be better explained on other principles: some plants extend their roots horizontally on the surface of the soil, others strike them downwards to a considerable depth. Some plants are found to bind or harden the soil, others to loosen it. Thus, for example, wheat and rye-grass render a soil stiff; while pulse, clover, and turnips, pulverize it. By varying the crops, therefore, the soil is preserved in a middle state, between too much stiffness and too much friability. Nor is this the only good effect arising from this difference of roots. From this circumstance some vegetables draw their nourishment from the surface of the earth, while others derive it partly from a greater depth; so that by a change of crops, a larger portion of the soil is made to contribute to the nourishment of plants than could have been effected by the cultivation of any single species. One other advantage to be derived from a change of crops is this: Some plants extract almost the whole of their nourishment from the soil; and this is particularly the case with those which are most valuable, and which contain the greatest quantity of solid matter. By the repetition of such crops, however, the soil is found to become too much exhausted. There are other plants which derive a large proportion of their nourishment from the air; by such therefore the soil will be much less exhausted, and under a crop of them will be in some measure at rest. The good effects of a change of crops may therefore be sufficiently explained, without supposing that each particular species of vegetables is nourished by a different kind of food. This opinion is also necessarily attended with two great difficulties; one is, that there exists in every soil as many distinct kinds of nourishment as there are species of plants capable of growing in that soil; the other, that plants are endued with the faculty of selecting, from all these kinds, their own proper nourishment. The former of these suppositions is too absurd to merit the least attention; and the latter has been disproved by actual experiment; since plants are not able to prevent their roots from absorbing such matters as prove poisonous to them. Other writers, however, have been more moderate; and though they have rejected the idea of specific nourishment in general, have nevertheless imagined that the hypothesis might be well founded with respect to particular species of vegetables. This they infer from the existence of specific manures, as soot for saintfoin, ashes for white clover, and some others. It does not seem possible, however, to draw a line of distinction; and if we reject the idea of a specific nourishment in general, we cannot admit it in particular instances.

In order to discover whether plants have an actual power of distinguishing matters presented to their roots, a gentleman of science made, among others, the following experiment:

A vigorous plant of mint was placed in a two-ounce phial, filled with filtrated well-water, to which were added four drops of a moderately strong solution of sulphate of iron. On examining the plant the following day, no other effect was observed, than that the very tips of the radicles were withered and black. Four more drops of the solution were now added. On the third day the appearances were the same; and no new change taking place on the fourth, twelve more drops of the solution were added. On the fifth day the roots appeared of a yellowish-green colour, and the top drooped very much. The larger leaves were pretty much withered and blackened. The absorption of the water appeared to be in some measure impeded, but not entirely prevented. On the sixth day the whole plant was withering very fast; the roots became of a dark olive-green colour, and the larger leaves were become very black, especially the footstalks and the projecting fibres. On the seventh day the blackness had made still further progress, and the plant was dead. A sufficient proof that some of the iron was absorbed by the plant, may be drawn from the following circumstance: Its leaves, when macerated in distilled water, produced a black colour with galls. The leaves of a plant of mint, which had been nourished by water alone, when tried by the same test, produced no colour whatever. This experiment proves two points; that plants have not the power of rejecting even injurious matters when presented to their roots, and that other matters besides water and air are capable of being absorbed by them.

The benefit produced by the common custom of letting lands lie fallow, has not yet been satisfactorily explained. Something may no doubt be attributed to the destruction of weeds, but more probably to some change produced in the soil by its being exposed to the action of the sun and air. The management of nitre-beds may tend to throw some light on this subject. These are composed of calcareous earth and dung cemented together. After being exposed for some months to the air, they are found to contain a quantity of nitric acid, which, uniting to the calcareous earth, forms a kind of salt, which is extracted by lixiviation. Now calcareous earth and dung are two of the most powerful kinds of manure, and it does not seem improbable that their fertilizing powers may be in some manner connected with their property of affording nitrous acid.

Vegetable substances. Plants contain various saline matters; such as the vegetable acids, and the three alkalies, ammonia, potass, and soda; also gum, sugar, fat oils, essential oils, balsams, camphor, resin, tar, farina, narcotic, and colouring matters; all which the reader will find treated of under their respective heads. But different kinds of plants contain matters peculiar to themselves, which an ingenious and profound modern chemist (Dr. Thomson) has classed under the general term extractive principle, and to which he ascribes the following general properties: 1st. Soluble in water, and the solution is always coloured. When the water is slowly evaporated, the extractive matter is obtained in a solid state, and transparent; but when the evaporation is rapid the matter is opaque. 2. The taste of extractive is always strong; but it is very different, according to the plant from which it is obtained. 3. Soluble in alcohol, but insoluble in ether. 4. By repeated solutions and evaporations, the extractive matter acquires a deeper colour, and becomes insoluble in water. This change is considered as the consequence of the absorption of the oxygen of the atmosphere, for which the extractive principle has a strong affinity: but if the solution is left to itself, exposed to the atmosphere, the extract is totally destroyed in consequence of a kind of putrefaction which speedily commences. 5. When oxymuriatic acid is poured into a solution containing extractive, a very copious dark-yellow precipitate is thrown down, and the liquid retains but a light lemon-colour. These flakes are the oxygenized extractive. It is now insoluble in water; but hot alcohol still dissolves it. 6. The extractive principle unites with alumina, and forms with it an insoluble compound. Accordingly, if sulphat or muriat of alumina is mixed with a solution of extractive, a flaky insoluble precipitate appears, at least when the liquid is boiled; but if an excess of acid is present, the precipitate does not always appear. 7. It is precipitated from water by concentrated sulphuric acid, muriatic acid, and probably by several other acids. When the experiment is made with sulphuric acid, the fumes of vinegar generally become sensible. 8. Alkalies readily unite with extractive, and form compounds which are soluble in water. 9. The greater number of metallic oxides form insoluble compounds with extractive. Hence many of them, when thrown into its solution, are capable of separating it from water. Hence also the metallic salts mostly precipitate extractive. Muriat of tin possesses this property in an eminent degeee. It throws down a brown powder, perfectly insoluble, composed of the oxide of tin and vegetable matter. 10. If wool, cotton, or thread, is impregnated with alum, and then plunged into a solution of extractive, they are dyed of a fawn-brown colour, and the liquid loses much of its extractive matter. This colour is permanent. The same effect is produced if muriat of tin is employed instead of alum. This effect is still more complete if the cloth is soaked in oxymuriatic acid, and then dipt into the infusion of extractive. Hence we see that the extractive matter requires no other mordant than oxygen to fix it on cloth. 11. When distilled, extractive yields an acid liquid impregnated with ammonia.

It cannot be doubted that there are many different species of extractive matter; though the difficulty of obtaining each separately has prevented chemists from ascertaining its nature with precision. Extracts in pharmacy are usually obtained by treating the vegetable substance from which they are to be procured with water, and then evaporating the watery solution slowly to dryness. All extracts obtained by this method have an acid taste, and redden the infusion of litmus. They all yield a precipitate while liquid, if they are mixed with ammonia. This precipitate is a compound of lime and insoluble extractive. Lime always causes them to exhale the odour of ammonia. It has been ascertained that the extractive principle is more abundant in plants that have grown to maturity than in young plants.

As the extracts of vegetables prepared by apothecaries for medical purposes, besides the extractive principle, always contain other bodies, frequently to the number of eight or more, and as the greater number of them are still but imperfectly examined, we shall satisfy ourselves at present with pointing out some of those vegetable substances which have been ascertained to contain extractive principle, and stating the constituents of such as have been analysed.

1. Extractive principle is not an uncommon ingredient in the sap of trees. Indeed, Deyeux and Vauquelin found it in almost all those which they examined. It is usually thrown down when the sap is mixed with oxymuriatic acid, and it precipitates in brown flakes while the sap is evaporating on a sand-bath.

2. It forms a constituent of the bark of all trees hitherto examined. This was evidently the case with all the barks which Mr. Davy subjected to experiment, namely, those of the oak, Leicester willow, Spanish chesnut, elm, common willow, and undoubtedly all barks which have an astringent taste; for tan and extractive seem scarcely ever to be found separate.

3. The infusion of catechu contains an extractive principle, united chiefly to tan. It may be obtained in a state of purity by washing the catechu in powder repeatedly with water till the fluids obtained cease to precipitate gelatine. What remains is extractive. It is of a pale reddish-brown colour, and a slightly astringent taste, leaving in the mouth a sensation of sweetness. It has no smell. Its solution in water is at first yellow-brown; but it acquires a tint of red when left exposed to the air. The solution in alcohol is of a dirty brown. It does not affect vegetable blues. Alkalies brighten its colour; but neither these bodies nor the alkaline earths precipitate it from water. Nitrat of alumina and muriat of tin render the solution slightly turbid. Nitrat of lead throws down a dense light-brown precipitate. It renders the oxysulphat of iron green, and throws down a green precipitate, becoming black by exposure to the air. Linen, when boiled in the solution, takes away almost the whole of the extractive, and acquires a light red-brown colour. When this extractive is exposed to heat, it softens, and its colour becomes darker, but it does not melt. When distilled, it yields carbonic and carbureted hydrogen gas, weak acetic acid, and a little unaltered extractive. A porous charcoal remains.

4. The infusion of senna contains a matter of a very peculiar nature, but which may be considered as a species of extractive. The senna of commerce consists of the dried leaves of the cassia senna, a shrublike annual, cultivated in Egypt. Water, at the ordinary temperature of the atmosphere, dissolves nearly one-half of the substance of these leaves. The infusion obtained has a brown colour, a bitter taste, and a peculiar aromatic odour. It contains a considerable proportion of carbonat of lime, sulphat of potass, and carbonat of magnesia, besides a little silica. But the most curious of its constituents is the extractive. When common air is made to pass for some hours through the infusion, a yellow-coloured precipitate appears: the same substance is thrown down immediately by muriatic acid and oxymuriatic acid. It appears also when a current of oxygen gas is made to traverse the infusion. This substance is the extractive altered by its combination with oxygen. It has a slight bitter taste. It is no longer soluble in water. Alcohol dissolves it, but lets it fall when diluted. The alkalies dissolve it, and form a deep-brown solution. On burning coals, it emits a thick smoke, exhales an aromatic odour, and leaves a spongy charcoal. These properties indicate a very decided approach to the resinous state.

5. The infusion of Peruvian bark likewise yields an extractive matter of a peculiar nature, which assumes a fine red colour when united to oxygen; and like the extractive of senna, acquires nearly the properties of a resin. It was obtained by Fourcroy from the cinchona of St. Domingo. Water, boiled on it till it refused to dissolve any thing more, was slowly evaporated, and the extract obtained was dissolved in alcohol. The alcohol, by evaporation, deposited the peculiar extractive. Its colour was brown, its taste bitter, insoluble in cold, but very soluble in hot, water. It was soluble in alcohol. When dry it was black, brittle, and broke with a polished fracture. Lime-water precipitated it in the state of a red powder; oxymuriatic acid threw it down in the state of a fine red powder, neither soluble in water nor alcohol, but capable of uniting with alkalies. A stronger dose of oxymuriatic acid renders it yellow.

6. Saffron yields extractive matter in great abundance. This substance consists of the summits of the pistils of the crocus sativus. Almost the whole of it is soluble in water.

The resemblance between extractive bodies and the colouring matter of plants is sufficiently striking. It is more than probable, that when this last set of bodies have been examined with more precision by chemists, they will be found to belong to the same class.

PLASHING *of quickset hedges*, an operation very necessary to promote the growth and continuance of old hedges.

It is performed in this manner: The old stubs must be cut off, &c. within two or three inches of the ground, and the best and longest of the middle-sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten feet distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all those shoots which are intended to be used either as stakes or the other work of the plashing: the ditch is to be cleaned out with the spade; and it must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch: all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this is done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone; whereas, what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

PLASTER. See PHARMACY.

Plasters are combinations of oils and metallic oxides destined to be spread upon leather or cloth, and in that state to be applied as a covering of ulcers, &c. They ought to be solid bodies, not so hard as to refuse to spread easily and equally, nor so soft as to run into oil when heated by the skin. They ought to admit of being easily kneaded when heated with the hand, to adhere firmly to the skin, but to be capable of being removed without leaving behind them any stain. Without these properties they do not answer the purpose for which they are destined, which is chiefly adhesion.

The only chemist who has hitherto examined plasters with attention is Deyeux, to whom we are indebted for some excellent observations on the method of preparing them.

The oxides hitherto employed for making plasters are those of lead; and litharge is usually considered as the best adapted for that purpose, of any of these oxides. But the oxides of several of the other metals, as bismuth and mercury, are also capable of forming plasters, and might perhaps in some cases be employed with advantage. Some metallic oxides, however, as those of iron, are not susceptible of that kind of combination with oils which constitutes plasters.

All the fixed oils are capable of forming plasters; but they do not all form plasters with the same properties. The drying oils, linseed-oil for instance, form plasters of a much softer consistency than the fat oils; but these last acquire the same properties as the drying oils, if they are combined with mucilage. Thus olive-oil, boiled for some time with linseed or fenugrec, forms with litharge plasters as soft as those composed of linseed-oil and litharge. According to Deyeux, olive-oil answers better for plasters than any other.

There are three different ways of forming plasters. The first consists in simply mixing together oil and litharge in proper proportions, and allowing the mixture to remain a considerable time in the common temperature of the atmosphere, agitating it occasionally. The oxide gradually loses its colour, and combines with the oil, and the mixture acquires consistence. This process is tedious, and does not furnish plasters sufficiently solid to answer the purposes for which they are intended. It is not therefore employed.

The second method consists in throwing the oxide into the oil while boiling. Plasters formed by this process have always a deep colour, and a peculiar odour, occasioned by the decomposition of a portion of the oil. When this process is followed, it is necessary that the oxide should be in the state of a fine powder; and that by agitation it should be made to combine with the oil as fast as possible, otherwise the metal will be revived altogether, in consequence of the strong tendency which oil has to combine with oxygen when raised to a high temperature.

The third method is most frequently practised, because it is not liable to the same inconveniences as the other two. This method consists in boiling the oil and the oxide together in a sufficient quantity of water. By this liquid the heat is moderated at first till the oil and oxide combine, which prevents the revival of the metal; and afterwards when the water is dissipated, the temperature is sufficiently high to give the plaster the requisite consistency.

Plasters, when long kept, become often too hard to be fit for use, especially if the requisite proportion of oil has not been employed at first. This defect is easily remedied, by melting them with a small portion of new oil. Plasters, when long kept, likewise change their colour, and most of their sensible properties; owing either to the absorption of oxygen, or to some change produced in their component parts by the action of the air.

PLASTICE, the *plastic art*, a branch of sculpture, being the art of forming figures of men, birds, beasts, fishes, &c. in plaister, clay, stucco, or the like. See SCULPTURE.

Plastice differs from carving in this, that the figures are made by the addition of what is wanting; but in carving always by subtracting what is superfluous. The plastic art is now chiefly used among us in fret-work ceilings; but the Italians apply it also to the mantlings of chimneys with great figures.

PLATALEA, the *spoonbill*, in ornithology, a genus belonging to the order of grallæ. The beak is plain, and dilates towards the point into an orbicular form; the feet have three toes, and are half-palmated. There are three species, distinguished by their colour: and of these species there are three varieties; two of which are called the white species, and one of the roseate.

1. The white species, which Linnæus calls platalea leucorodia, is about the size of a heron, but somewhat shorter in the neck and legs. The bill is more than half a foot long, and, like that of the rest of the genus, is shaped like a spoon: the colour of the bill is very various, being in some birds black, in others brown; the plumage is entirely white, though there have been specimens where the quills were tipped with black; the legs are generally either black or of a greyish-brown colour; between the toes there is a membrane connected to the outer one as far as the second joint, and to the inner as far as the first.

This bird is found in various parts of the Old Continent, and from the Ferro isles near Iceland to the Cape of Good Hope. It frequents the neighbourhood of the sea, and has been met with on the coasts of France; at Sevenhuys, near Leyden, once in great plenty, annually breeding in a wood there. The nest is placed on high trees near the sea-side. The female lays three or four white eggs, powdered with a few pale-red spots, and of the size of those of a hen. They are very noisy during breeding-time, like our rooks; are seldom found high up the rivers, chiefly frequenting the mouths of them. Their food is fish, which they are said not unfrequently to take from other birds, in the manner of the bald eagle; also mussels and other shell-fish, being found in greatest numbers where these are plenty; and they will also devour frogs and snakes, and even grass and weeds, which grow in the water, as well as the roots of reeds. They are migratory, retiring to the warmer parts as the winter approaches, and are rarely seen in England. Their flesh is said to have the flavour of a goose, and is eaten by some; and the young birds have been thought good food.

2. The roseate species, or platalea ajaja, is less than the white. The bill is marked all round with a furrow parallel to the edge, and is of a greyish-white colour, so transparent as to show the ramification of the blood-vessels belonging to it: the forehead is of a whitish colour between the bill, and eyes, and throat; the plumage is a fine rose-colour, deepest on the wings. A variety of this species is entirely of a beautiful red colour, having a collar of black at the lower part of the neck; the irides are red. It is said to be of a blackish chesnut the first year, becomes rose-coloured the second, and of a deep scarlet the third. It lives on small fish.

3. The dwarf species, or platalea pigmea, is about the size of a sparrow. The bill is black, longer than the head, flat at the end, and nearly of a rhomboidal form; the body is brown above and white beneath. It inhabits Surinam and Guiana.

PLATANUS, the *plane-tree*, a genus of the polyandria order, in the monœcia class of plants. The male calyx is an ament, globular; corolla scarcely apparent; anthers growing round the filament. Female calyx ament, globular; corolla many-petalled; stigma removed; seeds roundish, marcomate with the style, pappose at the base. The species are:

1. The orientalis, oriental or Eastern plane-tree, rises with a very straight smooth branching stem to a great height. It has palmated leaves, six or eight inches long and as much broad, divided into five large segments; having the side ones cut into two smaller, green above, and pale underneath; and long pendulous pedunculi, each sustaining several round heads of close-sitting very small flowers; succeeded by numerous downy seeds, collected into round, rough, hard balls. It is a native of Asia and many parts of the East, and grows in great plenty in the Levant.

2. The occidentalis, occidental or Western plane-tree, rises with a straight smooth stem to a great height, branching widely round; it has lobated leaves, seven or eight inches long, and from nine or ten to twelve or fourteen broad, divided into three large lobes; and very small flowers, collected into round heads, succeeded by round rough balls of seed. It is a native of Virginia and other parts of North America, where it attains an enormous size, and is remarkable for having

its stem all of an equal girt for a considerable length: we have an account of some trees being eight or nine yards in circumference, and which, when felled, afforded twenty loads of wood.

The varieties of these two species are the Spanish or middle plane-tree, having remarkably large leaves of three or five narrower segments; and the maple-leaved plane-tree, having smaller leaves, somewhat lobated into five segments, resembling the maple-tree leaf.

All these elegant trees are of hardy temperature, so as to prosper here in any common soil and exposure in our open plantations, &c. and are some of the most desirable trees of the deciduous tribe. Their propagation is by seed, layers, and cuttings. All the sorts will take tolerably by cutting off the strong young shoots; but the platanus occidentalis more freely than the oriental kind. Autumn is the best season: as soon as the leaf falls, choose strong young shoots, and plant them in a moist soil; many of them will grow, and make tolerable plants by next autumn.

PLATBAND *of a door or window*, is used for the lintel, where that is made square, or not much arched: these platbands are usually crossed with bars of iron when they have a great bearing, but it is much better to ease them by arches of discharge built over them.

PLATFORM, in the military art, an elevation of earth, on which cannon is placed to fire on the enemy: such are the mounts in the middle of curtins. On the ramparts there is always a platform, where the cannon are mounted. It is made by the heaping up of earth on the rampart; or by an arrangement of madriers, rising insensibly, for the cannon to roll on, either in a casement or on attack in the outworks. All practitioners are agreed that no shot can be depended on, unless the piece can be placed on a solid platform; for if the platform shakes with the first impulse of the powder, the piece must likewise shake, which will alter its direction, and render the shot uncertain.

Platform, or Orlop, in a ship of war, a place on the lower deck, abaft the main-mast, between it and the cockpit, and round about the main capstan, where provision is made for the wounded men in time of action.

PLATINA. See Platinum.

PLATING, is the art of covering baser metals with a thin plate of silver either for use or for ornament. It is said to have been invented by a spur-maker, not for show but for real utility. Till then the more elegant spurs in common use were made of solid silver; and from the flexibility of that metal, they were liable to be bent into inconvenient forms by the slightest accident. To remedy this defect, a workman at Birmingham contrived to make the branches of a pair of spurs hollow, and to fill that hollow with a slender rod of steel or iron. Finding this a great improvement, and being desirous to add cheapness to utility, he continued to make the hollow larger, and of course the iron thicker and thicker, till at last he discovered the means of coating an iron spur with silver in such a manner as to make it equally elegant with those which were made wholly of that metal. The invention was quickly applied to other purposes; and to numberless utensils which were formerly made of brass or iron are now given the strength of these metals, and the elegance of silver, for a small additional expence.

The silver plate was formerly made to adhere to the baser metal by means of solder; which is of two kinds, the soft and the hard, or the tin and silver solders. The former of these consists of tin alone, the latter generally of three parts of silver and one of brass. When a buckle, for instance, is to be plated by means of the soft solder, the ring, before it is bent, is first tinned, and then the silver-plate is gently hammered upon it, the hammer employed being always covered with a piece of cloth. The silver now forms, as it were, a mould to the ring, and whatever of it is not intended to be used is cut off. This mould is fastened to the ring of the buckle by two or three cramps of iron wire; after which the buckle, with the plated side undermost, is laid upon a plate of iron sufficiently hot to melt the tin, but not the silver. The buckle is then covered with powdered resin, or anointed with turpentine; and lest there should be a deficiency of tin, a small portion of rolled tin is likewise melted on it. The buckle is now taken off with tongs, and commonly laid on a bed of sand; where the plate and the ring, while the solder is yet in a state of fusion, are more closely compressed by a smart stroke with a block of wood. The buckle is afterwards bent and finished.

The mode of plating at present is, to fasten plates of silver upon thicker plates of copper, and then rolling them together into thin plates. The copper is twelve times thicker than the silver, and one ounce of silver is rolled to a surface of three feet or more. The plates being thus made, they are then stamped by a single stroke into the size and form of buckles, buttons, spoons, &c.

PLATINUM, one of the perfect metals, has hitherto been found only in Peru, and in the mine Santa Fe, near Carthagena. The workmen of these mines must no doubt have been early acquainted with it; but they seem to have paid very little attention to it. It was unknown in Europe till Mr. Wood brought some of it from Jamaica in 1741. In 1748 it was noticed by don Antonio de Ulloa, a Spanish mathematician, who had accompanied the French academicians to Peru, in their voyage to measure a degree of the meridian. Several papers on it were published by Dr. Watson in the 46th volume of the Philosophical Transactions. These immediately attracted the attention of the most eminent chemists. In 1752, Mr. Scheffer of Sweden published the first accurate examination of its properties. He proved it to be a new metal, approaching very much to the nature of gold, and therefore gave it the name of aurum album, white gold.

I. 1. Platinum, when pure, is of a white colour like silver, but not so bright. It has no taste nor smell.

2. Its hardness is 8. Its specific gravity, after being hammered, is 23.000; so that it is by far the heaviest body known

3. It is exceedingly ductile and malleable: it may be hammered out into very thin plates, and drawn into wires not exceeding $\frac{1}{1940}$ inch in diameter. In these properties it is probably inferior to gold, but it seems to surpass all the other metals.

4. Its tenacity is such, that a wire of platinum 0.078 inch in diameter, is capable of supporting a weight of 274.31 lbs. avoirdupois without breaking.

5. It is the most infusible of all metals, and cannot be melted, in any quantity at least, by the strongest artificial heat which can be produced. Macquer and Baumé melted small particles of it by means of a blow pipe, and Lavoisier by exposing them on red-hot charcoal to a stream of oxygen gas. It may indeed be melted without difficulty when combined or mixed with other bodies; but then it is not in a state of purity. Pieces of platinum, when heated to whiteness, may be welded together by hammering in the same manner as hot iron.

6. This metal is not in the smallest degree altered by the action of air or water.

II. It cannot be combined with oxygen and converted into an oxide by the strongest artificial heat of our furnaces. Platinum, indeed, in the state in which it is brought from America, may be partially oxidated by exposure to a violent heat, as numerous experiments have proved; but in that state it is not pure, but combined with a quantity of iron. It cannot be doubted, however, that if we could subject it to a sufficient heat, platinum would burn and be oxidated like other metals: for when Van Marum exposed a wire of platinum to the action of his powerful electrical machine, it burnt with a faint white flame, and was dissipated into a species of dust, which proved to be the oxide of platinum. By putting a platinum wire into the flame produced by the combustion of hydrogen gas mixed with oxygen, it was made to burn with all the brilliancy of iron wire, and to emit sparks in abundance. This metal may be oxidated in any quantity by boiling it in 16 times its weight of nitro-muriatic acid (aqua regia). The acid dissolves it, and assumes first a yellow, and afterwards a deep red or rather brown colour. On the addition of lime to the solution, a yellow powder falls to the bottom. This powder is the oxide of platinum. Its properties have not been examined with sufficient accuracy. It seems to contain but a small proportion of oxygen; probably not more than 0.07: yet it is in all probability a peroxide.

This oxide may be decomposed, and the oxygen driven off, by exposing it to violent heat.

III. Neither carbon nor hydrogen can be combined with platinum; but M. Proust has found it combined with sulphur in native platinum, and it unites without difficulty to phosphorus. By mixing together an ounce of platinum, an ounce of phosphoric glass, and a dram of powdered charcoal, and applying a heat of about 32° Wedgeworth, M. Pelletier formed a phosphuret of platinum weighing more than an ounce. It was partly in the form of a button, and partly in cubic crystals. It was covered above by a blackish glass. It was of a silver-white colour, very brittle, and hard enough to strike fire with steel. When exposed to a fire strong enough to melt it, the phosphorus was disengaged, and burnt on the surface.

He found also, that when phosphorus was projected on red-hot platinum, the metal instantly fused, and formed a phosphuret. As heat expels the phosphorus, Mr. Pelletier has proposed this as an easy method of purifying platinum.

IV. Platinum, as far as is known, does not combine with the simple incombustibles.

V. It combines with most of the metals, and forms alloys.

When gold and platinum are exposed to a strong heat, they combine, and form an alloy of gold and platinum. If the platinum exceeds $\frac{1}{17}$ of the gold, the colour of the alloy is much paler than gold; but if it is under $\frac{1}{17}$, the colour of the gold is not sensibly altered. Neither is there any alteration in the ductility of the gold. Platinum may be alloyed with a considerable proportion of gold, without sensibly altering its colour.

VI. The affinities of platinum are at present unknown. If this metal could be obtained at a cheap rate, it would furnish very useful vessels, that might be exposed to the greatest heat without alteration.

PLATONIC YEAR, or the GREAT YEAR, is a period of time determined by the revolution of the equinoxes, or the space wherein the stars and constellations return to their former places in respect of the equinoxes. The Platonic year, according to Tycho Brahe, is 25816, according to Ricciolus 25920, and according to Cassini 24800 years.

PLATOON, in the military art, a small square body of forty or fifty men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions or regiments. Platoons are also used when they form the hollow square, to strengthen the angles. The grenadiers are generally posted in platoons.

PLATYLOBIUM, a genus of the diadelphia decandria class and order. The calyx is bell-shaped, five-cleft; the two upper segments very large; legume pedicelled, compressed, winged at the back. There is one species, a shrub of South Wales.

PLATYPUS, a quadruped of the order of bruta. The generic character is, mouth shaped like the bill of a duck; feet webbed. Of this extraordinary genus two specimens have been sent from New Holland to sir Joseph Banks by governor Hunter.

Of all the mammalia yet known, this seems the most extraordinary in its conformation; exhibiting the perfect resemblance of the beak of a duck engrafted on the head of a quadruped. So accurate is the similitude, that, at first view, it naturally excites the idea of some deceptive preparation by artificial means; the very epidermis, proportion, serratures, manner of opening, and other particulars of the beak of a shoveler, or other broad-billed species of duck, presenting themselves to the view: nor is it without the most minute and rigid examination that we can persuade ourselves of its being the real beak or snout of a quadruped.

The body is depressed, and has some resemblance to that of an otter in miniature. It is covered with a very thick, soft, and beaver-like fur, and is of a moderately dark brown above, and of a subferruginous white beneath. The head is flattish, and rather small than large; the mouth or snout, as before observed, so exactly resembles that of some broad-billed species of duck, that it might be mistaken for such: round the base is a flat circular membrane, somewhat deeper or wider below than above, viz. below nearly the fifth of an inch, and above about an eighth. The tail is flat, furry like the body, rather short and obtuse, with an almost bifid termination; it is broader at the base, and gradually lessens to the tip, and is about three inches in length; its colour is similar to that of the body. The length of the whole animal from the tip of the beak to that of the tail is 13 inches; of the beak an inch and a half. The legs are very short, terminating in a broad web, which on the fore feet extends to a considerable distance beyond the claws; but on the hind-feet reaches no farther than the roots of the claws. On the fore-feet are five claws, straight, strong, and sharp-pointed; the two exterior ones somewhat shorter than the three middle ones. On the hind-feet are six claws, longer and more inclining to a curved form than those on the fore-feet; the exterior toe and claw are considerably shorter than the four middle ones; the interior or sixth is seated much higher up than the rest, and resembles a strong sharp spur. All the legs are hairy above; the fore-feet are naked both above and below; but the hind-feet are hairy above, and naked below. The internal edges of the under mandible (which is narrower than the upper) are serrated or channeled with numerous striæ, as in a duck's bill. The nostrils are small and round, and are situated about a quarter of an inch from the tip of the bill, and are about the eighth of an inch distant from each other. There is no appearance of teeth; the palate is removed, but seems to have resembled that of a duck; the tongue also is wanting in the specimen. The ears, or auditory foramina, are placed about an inch beyond the eyes; they appear like a pair of oval holes, of the eighth of an inch in diameter, there being no external ear. On the upper part of the head, on each side, a little beyond the beak, are situated two smallish oval white spots; in the lower part of each of which are imbedded the eyes, or at least the parts allotted to the animal for some kind of vision; for from the thickness of the fur, and the smallness of the organs, they seem to have been but obscurely calculated for distinct vision, and are probably like those of moles, and some other animals of that tribe; or perhaps even subcutaneous; the whole apparent diameter of the cavity in which they were placed not exceeding the tenth of an inch.

When we consider the general form of this animal, and particularly its bill and webbed feet, we shall readily perceive that it must be a resident in watery situations; that it has the habits of digging or burrowing in the banks of rivers or under ground; and that its food consists of aquatic plants and animals. This is all that can at present be reasonably guessed at: future observations, made in its native regions, will, it is hoped, afford us more ample information, and will make us fully acquainted with the natural history of an animal which differs so widely from all other quadrupeds, and which verifies, in a most striking manner, the observation of Buffon, viz. that whatever was possible for nature to produce, has actually been produced.

The platypus is a native of Australasia or New Holland.

PLEA, that which either party alleges for himself in court. These are divided into pleas of the crown and common pleas.

Pleas of the crown are all suits in the king's name, against offences committed against his crown and dignity, or against his crown and peace. Common pleas are those that are held between common persons.

Common pleas are either dilatory, or pleas to the action.

Pleas dilatory are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy rather than by denying the injury.

Pleas to the action are such as dispute the very cause of suit. 3 Black. 301. See Tidd's K. B. Practice.

PLEADINGS, in general, signify the allegations of parties to suits when they are put into a proper and legal form; and are distinguished in respect to the parties who plead them, by the names of bars, replications, rejoinders, sur-rejoinders, rebutters, sur-rebutters, &c. and though the matter in the declaration of court does not properly come under the name of pleading, yet, being often comprehended in the extended sense of the word, it is generally considered under this head. See Tidd's K. B. Practice.

PLEBISCITUM, in Roman antiquity, a law enacted by the common people, at the request of the tribune, or other plebeian magistrate, without the intervention of the senate.

PLECTRANTHUS, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The calyx is monophyllous, short, and bilabiated; the upper lip of which is large, oval, and bent upwards; the inferior lip is quadrifid, and divided into two laciniæ: the corolla is monopetalous, ringent, and turned back; the labiæ look different ways, and from the base of the tube there is a nectarium like a spur: the filaments are in a declining situation, with simple antheræ: the stylus filiform; the stigma bifid. It has four seeds, covered only by the calyx. There are five species: the fruticosus is a native of the Cape of Good Hope; the punctatus is a native of Africa. The first flowers from June to September, the latter from January to May.

PLECTROMIA, a genus of the class and order pentandria monogynia. The petals are five; berry two-seeded, inferior. There is one species, a tree of the Cape.

PLEIADES, in astronomy, an assemblage of stars in the neck of the constellation Taurus. See ASTRONOMY.

PLENE ADMINISTRAVIT, a plea pleaded by an executor or administrator, where they have administered the deceased's estate faithfully and justly before the action brought against them.

PLENUM, in physics, denotes, according to the Cartesians, that state of things wherein every part of space is supposed to be full of matter; in opposition to a vacuum.

PLENUS FLOS. See BOTANY, Vol. I. p. 251.

PLETHORA. See MEDICINE.

PLEURA. See ANATOMY.

PLEURISY. See MEDICINE.

PLEURONECTES, *flounder*, a genus of fishes of the order thoracici, of which there are 17 species. The generic character is, eyes both on the same side of the head; body compressed, one side representing the back, and the other the abdomen.

The singular structure of this genus is justly considered as one of the most curious deviations from the general uniformity or regularity observed by nature in the external figure of animals, in which (except in a very few instances) both sides of the body are perfectly similar: but in the genus pleuronectes the animal is so constituted, that one side appears to represent the back, and the opposite side the abdomen. They swim laterally, and the eyes are always placed on one side. It is from this circumstance that the division of the species is conducted, viz. into those which have the eyes dextrous, or towards the right, when the fish is laid with its coloured side upwards with its abdomen towards the spectator; and sinistrous when the eyes are towards the left in the above situation of the fish. It is said, however, that instances have sometimes occurred in which this natural situation has been reversed; but such instances must be considered as extremely rare.

1. Pleuronectes hippoglossus, holibut, with eyes towards the right. This species not only exceeds in size all the rest of the present genus, but may even be considered as one of the largest of fishes; having been sometimes found of the weight of three, and even, according to some accounts, four hundred pounds. It is a native of the Mediterranean and northern seas, and appears to arrive at its greatest size in the latter. It is considered as the most voracious of its tribe; preying on a variety of other fishes, as well as on different kinds of crabs, shell-fish, &c. The holibut is, however, of a longer or more slender form than most other flat fish: its colour is deep-brown above, and white beneath; the body being quite smooth, and covered with moderately small scales. As a food it is considered as very coarse in comparison with many others of this genus. In the London markets this fish is usually cut into large pieces when exposed to sale. The Greenlanders are said to cut it into thin slips, which they dry in the sun, and thus preserve for winter use.

2. Pleuronectes platessa, plaise. This species is, in general, easily distinguished at first sight from others of the genus by its shape and colours; being very broad and flat, and of a fine palish brown above, marked both on the body and fins by pretty numerous, but rather distant, round, and moderately large, orange-coloured spots: the under side is white; behind the left eye is a row of six tubercles, reaching as far as the commencement of the lateral line; the mouth is rather small, the lower jaw longer than the upper, and both furnished with a row of small and rather blunt teeth.

The plaise is an inhabitant of the Mediterranean, Baltic, and northern seas, and is found in considerable plenty about our own coasts. Mr. Pennant observes, that it is sometimes taken of the weight of 15 pounds; but its more general weight is far short of this, one of eight or nine pounds being reckoned a large fish. The best are said to be taken off Rye on the coast of Sussex, and about the Dutch coasts. They spawn in the beginning of May. Their general food consists of small fishes, sea-insects, and the smaller kinds of shell-fish.

The plaise is in considerable esteem as a food, though far inferior to the sole and turbot. Those are most esteemed which are of moderate size, the smaller ones being less firm than those of more advanced growth.

3. Pleuronectes limanda, dab. The dab is of a very broad ovate shape, of a yellowish brown colour above, and white beneath. It is covered with moderately large rough scales. The head is small, and the eyes large; the mouth small, and the teeth are more numerous in the upper jaw than in the lower; the dorsal and anal fins are of moderate width, and the tail nearly even at the end; the lateral line curves downwards over the pectoral fins, and from thence runs straight to the tail.

This species is an inhabitant of the Mediterranean, the Baltic, and the northern seas, but is less common than either the plaise or flounder, to both of which it is superior as a food, though inferior in its general size. It is in its highest season in the months of February, March, and April, after which it is observed to grow less firm. It spawns in May, or, if the spring proves cold, in June.

4. Pleuronectes flesus. The flounder is allied to the plaise in shape, but is generally of smaller size and of more obscure colours; the upper side being of a dull brown, marbled with paler and darker variegations, and the under side of a dull white, sometimes obscurely varied with brown; the body is covered with very small scales; and along the back, at the base of the dorsal fin, runs a row of small sharp spines; a similar row runs along the base of the anal fin: the lateral line is marked by a third row, continued almost to the base of the tail, which is slightly rounded at the end: at the commencement of the anal fin is a pretty strong spine.

The flounder is an inhabitant of the Northern, Baltic, and Mediterranean seas. About our own coasts it is extremely common, and even frequents our rivers at a great distance from the salt waters. It is in considerable esteem as a food, though much inferior to some others of the genus.

The pleuronectes passer of Linnæus, considered by Mr. Pennant and some others as a variety of the flounder, having the eyes on the left side, is at present allowed to constitute a distinct species.

5. Pleuronectes solea. The sole is an inhabitant of the Northern, Baltic, and American seas, and grows to the length of more than two feet, and to the weight of eight pounds. Its general size, however, is much smaller. Its shape is that of a very long oval; its colour obscure brown above, and white beneath. It is covered with small rough scales of an oblong form, each terminated by numerous spines, and very strongly fastened to the skin. These scales, from the elegance of their structure, form a favourite microscopic object; and an erroneous idea sometimes prevails, that the spiny end of the scale is that by which it was inserted into the skin. The pectoral fins, especially that on the upper side, are commonly tipped with black.

Next to the turbot, this fish is considered as the most delicate of the genus, and is by many even preferred to the former; the flesh being remarkably firm, white, and well-flavoured: those of moderate size are in general most esteemed. The sole delights in lying at the bottom of the coasts which it frequents, preying on small shell-fish, spawn, sea-insects, &c. and is generally taken by the trawl-net. The chief fishery, according to Mr. Pennant, is at Brixham in Torbay.

6. Pleuronectes tuberculatus, with eyes towards the left. The turbot, generally considered as superior to every other species as an article of food, is an inhabitant of the Mediterranean and Northern seas, where it often arrives at a very large size. It is, however, far inferior in this respect to the holibut, and is therefore not very happily distinguished by Linnæus under the name of pleuronectes maximus. It is of a broader and squarer form than any other of the genus, except the pearl; and is of a dark brown above, marbled with blackish spots of different sizes, and white beneath; the scales are so small as to be scarcely observable, but the skin is of a wrinkled appearance, and covered with pretty numerous and moderately large pointed tubercles or abrupt spines, those on the upper or coloured side being far larger than those on the under side: the lateral line forms an arch over the pectoral fins, and thence runs straight to the tail.

Like the rest of this genus, the turbot generally lies in deep water, preying on worms, shell-fish, and marine insects, as well as on various kinds of small fishes. It is taken in great quantities about the northern coasts of England, as well as on those of France, Holland, &c. and is baited for with pieces of herring, haddock, &c. but more particularly with the smaller or river lamprey, vast quantities of which are said to be purchased of our fishermen by the Dutch, to the annual amount of not less than 700 pounds. They are chiefly taken about Mortlake, and sold to the Dutch as bait for the cod-fishery; but that people are said to have the art of preserving them till the commencement of the turbot-fishery.

The general manner in which the turbot-fishery is practised at Scarborough, is thus detailed by Mr. Pennant, in the British Zoology, from the communications of Mr. Travis of that place:

"When they go out to fish, each man is provided with three lines. Each man's lines are fairly coiled upon a flat oblong piece of wicker-work; the hooks being baited, and placed very regularly in the centre of the coil. Each line is furnished with fourteen score of hooks, at the distance of six feet two inches from each other. The hooks are fastened to the lines upon sneads of twisted horse hair 17 inches in length. When fishing there are always three men in each coble; and consequently nine of these lines are fastened together, and used as one line, extending in length nearly three miles, and furnished with 2520 hooks. An anchor and a buoy are fixed at the first end of the line, and one more at each end of each man's lines, in all four anchors, which are commonly perforated stones, and four buoys, made of leather and cork. The line is always laid across the current. The tides of flood and ebb continue an equal time upon our coast; and when undisturbed by winds, run each way about six hours: they are so rapid, that the fishermen can only shoot and haul their lines at each turn of the tide; and therefore the lines always remain on the ground about six hours. The same rapidity of the tide prevents their using hand-lines; and therefore two of the people commonly wrap themselves in the sail and sleep, while the other keeps a strict look-out, for fear of being run down by ships, and to observe the weather; for storms often rise so suddenly, that it is with extreme difficulty they can escape to shore, leaving their lines behind. The coble is twenty feet six inches long, and five feet in extreme breadth: it is about one ton burthen, rowed with three pair of oars, and admirably constructed for the purposes of encountering a mountainous sea. They hoist sail when the wind suits."

PLICA POLONICA. See MEDICINE.

PLINIA, a genus of plants of the polyandria monogynia class. The empalement is divided into five segments; the flower consists of five petals; the stamina are numerous filaments, slender, and as long as the flower; the antheræ are small, and so is the germen of the pistil; the style is subulated, and of the length of the stamina; the stigma is simple; the fruit is a large globose berry, of a striated or sulcated surface, containing only one cell, in which is a very large, smooth, and globose seed. There are two species, trees of America.

PLINTH. See ARCHITECTURE.

PLOCAMA, a genus of the monogynia order, in the pentandria class of plants. The calyx is quinquedentate; the fruit a berry and trilocular, with solitary seeds. Of this there is only one species, viz. the pendula, a native of the Canaries.

PLOTTING, among surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain. See SURVEYING.

PLOTUS, or DARTER, a genus of birds of the order anseres. The generic character is, bill straight, pointed, toothed; nostrils a slit near the base; face and chin naked; legs short, all the toes connected. Of this genus there are three species.

P. anhinga: head smooth; belly white: inhabits Brasil; two feet ten inches long; builds on trees, and is hardly ever seen on the ground: when at rest, sits with the neck drawn in between the shoulders; flesh oily and rancid.

P. melanogaster, inhabits Ceylon and Java; about three feet long: and the P. surinamensis, has its head crested, and belly white; it inhabits Surinam; is 13 inches long; is domesticated, and feeds on fish, insects, especially flies, which it catches with great dexterity, and is very active.

PLOVER. See CHARADRIUS.

PLOUGH. See HUSBANDRY.

PLOUGHING. See HUSBANDRY.

PLUKENETIA, a genus of the monœcia monadelphia class and order. The male and female flowers are produced separately on the same plant; the corolla is composed of four oval and patent petals, and the stamina form a short pyramidal body: the fruit is a depressed quadrangular capsule, containing a single roundish and compressed seed. There is one species.

PLUM-TREE. See PRUNUS.

PLUMBAGO, *lead-wort*, a genus of the monogynia order, in the pentandria class of plants. The corolla is funnel-form; stamina inserted in scales, inclosing the base of the corolla; stigma five-cleft; seed one. There are seven species, the most remarkable of which are the Europæa and Zeylonica. The first grows naturally in the southern parts of Europe, and has a perennial root striking deep in the ground. There are many slender enamelled stalks, about three feet high, terminated by tufts of small funnel-shaped flowers, of a blue or white colour. The second grows naturally in both the Indies. The upper part of the stalk and empalement are covered with a glutinous juice, which catches the small flies that light upon it. The former species is propagated by parting the roots, and by seeds; but the latter is too tender to thrive in the open air in this country.

PLUMBAGO, carburet of iron. This mineral is found in various parts of Europe and America. It occurs in kidney-form lumps of various sizes. Its colour is dark iron-grey, or brownish-black; when cut, blueish-grey. Opaque and slaty; texture fine-grained; brittle; specific gravity from 1.98 to 2.09; feels somewhat greasy; stains the fingers, and marks strongly. The use of this mineral, when manufactured into pencils, is known to every person. It consists of

90 of carbon
10 of iron
———
100.

PLUMBERY, the art of casting and working lead, and using it in buildings.

As this metal melts very easily, it is easy to cast it into figures of any kind, by running it into moulds of brass, clay, plaister, &c. But the chief article in plumbery is sheets and pipes of lead; and as these make the basis of the plumber's work, we shall here give the process of making them.

In casting sheet-lead, a table or mould is made use of, which consists of large pieces of wood well jointed, and bound with bars of iron at the ends; on the sides of which runs a frame consisting of a ledge or border of wood, two or three inches thick, and two or three inches high from the mould, called the sharps: the ordinary width of the mould, within these sharps, is from three to four feet, and its length is 16, 17, or 18 feet. This should be something longer than the sheets are intended to be, in order that the end where the metal runs off from the mould may be cut off; because it is commonly thin, or uneven, or ragged at the end. It must stand very even or level in breadth, and something falling from the end in which the metal is poured in, viz. about an inch or an inch and a half, in the length of 16 or 17 inches. At the upper end of the mould stands the pan, which is a concave triangular prism, composed of two planks nailed together at right angles, and two triangular pieces fitted in between them at the ends. The length of this pan is the whole breadth of the mould in which the sheets are cast; it stands with its bottom, which is a sharp edge, on a form at the end of the mould, leaning with one side against it; and on the opposite side is a handle to lift it up by, to pour out the melted lead; and on that side of the pan next the mould, are two iron hooks to take hold of the mould, and prevent the pan from slipping, while the melted lead is pouring out of it into the mould. This pan is lined on the inside with moistened sand, to prevent it from being fired by the hot metal. The mould is also spread over, about two-thirds of an inch thick, with sand sifted and moistened, which is rendered perfectly level by moving over it a piece of wood called a strike, by trampling upon it with the feet, and smoothing it over with a smoothing-plane; which is a thick plate of polished brass, about nine inches square, turned up on all the four edges, and with a handle fitted on to the upper or concave side. The sand being thus smoothed, it is fit for casting sheets of lead; but if they would cast a cistern, they measure out the size of the four sides, and having taken the dimensions of the front or fore-part, make mouldings by pressing long slips of wood, which contain the same mouldings into the level sand; and form the figures of birds, beasts, &c. by pressing in the same manner leaden figures upon it, and then taking them off, and at the same time smoothing the surface where any of the sand is raised up by making these impressions upon it. The rest of the operation is the same in casting either cisterns or plain sheets of lead. But before we proceed to mention the manner in which that is performed, it will be necessary to give a more particular description of the strike.

The strike then is a piece of board about five inches broad, and something longer than the breath of the mould on the inside; and at each end is cut a notch, about two inches deep, so that when it is used, it rides upon the sharps with those notches. Before they begin to cast, the strike is made ready by tacking two pieces of an old hat on the notches, or by slipping a case of leather over each end, in order to raise the under side about one-eighth of an inch, or something more, above the sand, according as they would have the sheet to be in thickness; then they tallow the under edge of the strike, and lay it across the mould. The lead being melted, it is laded into the pan, in which, when there is a sufficient quantity for the present purpose, the scum of the metal is swept off with a piece of board to the edge of the pan, letting it settle on the sand, which is by this means prevented from falling into the mould at the pouring out of the metal. When the lead is cool enough, which is known by its beginning to stand with a shell or wall on the sand round the pan, two men take the pan by the handle, or else one of them lifts it up by a bar and chain fixed to a beam in the ceiling, and pour it into the mould, while another man stands ready with the strike, and, as soon as they have done pouring in the metal, puts on the mould, sweeps the lead forward, and draws the overplus into a trough prepared to receive it. The sheets being thus cast, nothing remains but to planish the edges, in order to render them smooth and straight; but if it is a cistern, it is bent into four sides, so that the two ends may join the back, where they are soldered together, after which the bottom is soldered up.

The method of casting pipes without soldering. To make these pipes, they have a kind of little mill, with arms or levers to turn it with. The moulds are of brass, and consist of two pieces, which open and shut by means of hooks and hinges, their inward caliber or diameter being according to the size of the pipe to be made, and their length is usually two feet and a half. In the middle is placed a core, or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inward diameter of the pipe. This core is passed through two copper-rundles, one at each end of the mould, which they serve to close; and to these is joined a little copper tube about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, they take it up in a ladle and pour it into the mould by a little aperture at one end, made in the form of a funnel. When the mould is full, they pass a hook into the end of the core, and turning the mill, draw it out; and then opening the mould, take out the pipe. If they desire to have the pipe lengthened, they put one end of it in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before, the pipe just cast serving for rundle, &c. at the other end. Things being thus replaced, they pour in fresh metal, and repeat the operation till they have got a pipe of the length required.

For making pipes of sheet-lead, the plumbers have wooden cylinders of the length and thickness required, and on these they form their pipes by wrapping the sheet around them, and soldering up the edges all along them. See Pipe.

PLUMERIA, a genus of the pentandria monogynia class of plants, the corolla of which consists of a single funnel-like petal, with a long tube, and divided into five oblong segments at the limb: the fruit is composed of two jointed and ventricose follicles, formed of a single valve each, and containing numerous oblong seeds. There are four species.

PLUMMET, plumb-rule or plumb-line, an instrument used by carpenters, masons, &c. in order to judge whether walls. &c. are upright planes, horizontal, or the like. It is thus called from a piece of lead, plumbum, fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, &c. raised perpendicularly on another, in which case it becomes a level. See Level.

PLUMMING, among miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: A skilful person, with an assistant, and with pen, ink, and paper, and a long line, and a sun-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the incited needle is let to rest, and the exact point where it rests is marked with a pen; he then goes on farther in the line still fastened, and at the next flexure on the adit he makes a mark on the line by a knot or otherwise; and then letting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds, from turning to turning, marking down the points, and marking the line, till he comes to the intended place; this done, he ascends and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he comes to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUNGER, in mechanics, the same with the forcer of a pump. See Pump.

PLURALITY. If any person having one benefice with cure of souls of eight pounds a year in the king's books, shall accept another of whatsoever value, and be instituted and inducted into the same, the former benefice shall be void; unless he has a dispensation from the archbishop of Canterbury, who has power to grant dispensations to chaplains of noblemen and others under proper qualifications, to hold two livings, provided they are not more than thirty miles distant from each other, and provided that he resides in each for a reasonable time every year, and that he keeps a sufficient curate in that in which he does not ordinarily reside.

PLUS, in algebra, a character marked thus +, used for the sign of addition. See Character.

PLUSH, in commerce, &c. a kind of stuff leaving a sort of velvet knap, or shag, on one side, composed regularly of a woof of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goats or camel's hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

Plush is manufactured, like velvet, on a loom with three treadles; two of these separate and depress the woollen warp, and the third raises the hair warp, upon which the workman throwing the shuttle, passes the woof between the woollen and hair warp; and afterwards laying a brass broach, or needle, under that of the hair, he cuts it with a knife destined for that use; conducting the knife on the broach, which is made a little hollow all its length, and thus gives the surface of the plush an appearance of velvet. See Velvet.

There are other kinds of plush, all of silk; some of which have a pretty long knap on one side, and some on both.

PLUVIAMETER, a machine for measuring the quantity of rain that falls. Fig. 16, Plate I. Pneumatics, shews the section of a very good pluviameter. It consists of a hollow cylinder, having within it a cork ball attached to a wooden stem, which passes through a small opening at top, on which is placed a large funnel. When this instrument is placed in the open air in a free place, the rain that falls within the circumference of the funnel will run down into the tube, and cause the cork to float, and the quantity of water in the tube may be seen by the height to which the stem of the float is raised. The stem of the float is so graduated, as to shew by its divisions the number of perpendicular inches of water which fell on the surface of the earth since the last observation.

A very simple pluviameter, and which will answer all practical purposes, consists simply of a copper funnel, the area of whose opening is exactly ten inches; this funnel is fixed in a bottle, and the quantity of rain caught is ascertained by multiplying the weight in ounces by .173, which gives the depth in inches and parts of an inch.

PNEUMATICS. Though the word pneumatics means, strictly, the science which treats of the properties of air in general, yet it is commonly used to express the mechanical properties of elastic or aeriform fluids; such as their weight, density, compressibility, and elasticity. The other properties of elastic fluids are treated of under Chemistry and Air.

The air is a fluid in which we live and breathe: it entirely envelopes our globe, and extends to a considerable height around it. Together with the clouds and vapours that float in it, it is called the atmosphere. As it is possessed of gravity in common with all other fluids, it must press upon bodies in proportion to the depth at which they are immersed in it; and it also presses in every direction, in common with all other fluids.

It differs from all other fluids in the four following particulars: 1. It can be compressed into a much less space than it naturally possesses; 2. It cannot be congealed or fixed as other fluids may; 3. It is of a different density in every part upward from the earth's surface; decreasing in its weight, bulk for bulk, the higher it rises; 4. It is of an elastic or springy nature, and the force of its spring is equal to its weight.

Few people who are unacquainted with the principles of natural philosophy, suppose that the air by which we are surrounded is a material substance, like water, or any other visible matter. Being perfectly invisible, and affording no resistance to the touch, it must seem to them extraordinary, to consider it as a solid and material substance; and yet a few simple experiments will convince any one that it is really matter, and possesses weight, and the power of resisting other bodies that press against it.

Take a bladder that has not the neck tied, and you may press the sides together, and squeeze it into any shape. Fill this bladder with air, by blowing into it, and tie a string fast round the neck: you then find that you cannot, without breaking the bladder, press the sides together, and that you can scarcely alter its figure by any pressure. Whence then arise these effects? When the bladder was empty, you could press it into any form; but the air with which it is filled, prevents this: the resistance you experience when it is filled with air, proves that that is real matter as well as any other substance that we are acquainted with.

We are accustomed to say, that a vessel is empty, when we have poured out of it the water which it contained. Throw a bit of cork upon a bason of water, and having put an empty tumbler over it with the mouth downwards, force it down through the water; the cork will shew the surface of the water within the tumbler, and you will see that it will not rise so high within as without the glass; nor, if you press ever so hard, will it rise to the same level. The water is, therefore, prevented from rising within the tumbler, by some other substance which already occupies the inside; which substance is the air that filled the tumbler when it was inverted, and which could not escape, on account of the superior pressure of the water.

In like manner, having opened a pair of common bellows, stop up the nozzle securely, and you will find that you cannot shut the bellows, which seems to be filled with something that yields a little, like wool; but if you unstop the nozzle, the air will be expelled, and may be felt against the hand.

When the air is at rest, we can move in it with the utmost facility; nor does it offer to us a sensible resistance, except the motion is quick, or the surface opposed to it considerable; but when that is the case, its resistance is very sensible, as may be easily perceived by the motion of a fan.

When air is in motion, it constitutes wind; which is nothing more than a current or stream of air, varying in its force, according to the velocity with which it flows.

The invisibility of air, therefore, is only the consequence of its transparency; but it is possessed of all the common properties of matter. When a vessel is empty, in the usual way of speaking, it is in fact still filled with air.

But it is possible to empty a vessel even of the air which it contains, by which means we shall be able to discover several properties of this fluid. The instrument, or machine, by which this operation is performed, is called an air-pump. As it is by means of this useful instrument that all the mechanical properties of air are demonstrated, it will be necessary to describe its construction, and the manner of using it, before we proceed to the experiments that are made with it.

Plate I. Pneumatics, fig. 1. is the air-pump that is now most in use. AA are two brass barrels, each containing a piston, with a valve opening upwards. They are worked by means of the winch B, which has a pinion that fits into the teeth of the racks CC, which are made upon the ends of the pistons, and by this means moves them up and down alternately.

On the square wooden frame DE, there are placed a brass plate G, ground perfectly flat, and also a brass tube, let into the wood, communicating with the two barrels and the cock I, and opening into the centre of the brass plate at *a*. The glass vessel K, to be emptied or exhausted of air, has its rim ground quite flat, and rubbed with a little pomatum, or hog's-lard, to make it fit more closely upon the brass plate of the pump. These vessels are called receivers. Having shut the cock I, the pistons are worked by the winch; and the air being suffered to escape when the piston is forced down, because the valve opens upwards, but prevented from returning into the vessel for the same reason, the receiver is gradually exhausted, and will then be fixed fast upon the pump-plate. By opening the cock I, the air rushes again into the receiver.

"As light as air," is a common saying; yet air can be shewn to have more weight than is generally supposed. Take a hollow copper ball, or other vessel, which holds a wine quart, having a neck to screw on the plate of the air-pump; and after weighing it when full of air, exhaust it, and weigh it when empty; it will be found to have lost sixteen grains, which shews that this is the weight of a quart of air. But a quart of water weighs 14621 grains: this divided by 16, quotes 914 in round numbers; so that water is 914 times as heavy as air near the surface of the earth. This supposes air at a medium temperature and density; for these, as will be seen afterwards, are variable.

When the receiver is placed upon the plate of the air-pump without exhausting it, it may be removed again with the utmost facility, because there is a mass of air under it, that resists by its elasticity the pressure on the outside; but exhaust the receiver, thus removing the counter-pressure, and it will be held down to the plate by the weight of the air upon it.

What the pressure of the air amounts to, is exactly determined in the following manner:

When the surface of a fluid is exposed to the air, it is pressed by the weight of the atmosphere equally on every part, and consequently remains at rest. But if the pressure is removed from any particular part, the fluid must yield in that part, and be forced out of its situation.

Into the receiver A (fig. 2.) put a small vessel with quicksilver, or any other fluid, and through the collar of leathers at B, suspend a glass tube, closed, or hermetically sealed, as it is called, over the small vessel. Having exhausted the receiver, let down the tube into the quicksilver, which will not rise into the tube as long as the receiver continues empty. But re-admit the air, and the quicksilver will immediately ascend. The reason of this is, that upon exhausting the receiver, the tube is likewise emptied of air; and therefore, when it is immersed in the quicksilver, and the air re-admitted into the receiver, all the surface of the quicksilver is pressed upon by the air, except that portion which lies above the orifice of the tube; consequently, it must rise in the tube, and continue so to do, until the weight of the elevated quicksilver presses as forcibly on that portion which lies beneath the tube, as the weight of the air does on every other equal portion without the tube.

Take a common syringe of any kind, and having pushed the piston to the farthest end, immerse it into water; then draw up the piston, and the water will follow it. This is owing to the same cause as the last: when the piston is pulled up, the air is drawn out of the syringe with it, and the pressure of the atmosphere is removed from the part of the water immediately under it; consequently the water is obliged to yield in that part to the pressure on the surface.

It is upon this principle that all those pumps called sucking-pumps act: the piston fitting tightly the inside of the barrel, by being raised up, removes the pressure of the atmosphere from that part, and consequently the water is drawn up by the pressure upon the surface.

In the beginning of the last century, philosophers were of opinion that the ascent of water in pumps, was owing to what they called "Nature's abhorrence of a vacuum;" and that, by means of suction, fluids might be raised to any height whatever.

Galileo was the first who discovered that it was impossible to raise water higher than thirty-three feet by suction only; and thence concluded, that not the power of suction, but the pressure of the atmosphere, was the cause of the ascent of water in pumps; that a column of water thirty-three feet high was a counterpoise to one as high as the atmosphere; and that, for this reason, the water would not follow the sucker any farther.

His pupil Torricelli, considered that as mercury was fourteen times as heavy as water, a column of that fluid need only be one-fourteenth of the length of one of water, to form an equal counterpoise to the pressure of the air; and accordingly, having filled with mercury a glass tube about three feet long, hermetically sealed at one end, he inverted it into a small bason of mercury, and found, as he expected, that the mercury subsided to the height of about twenty-nine inches and a half, and there remained suspended, leaving a space at the top of the tube a perfect vacuum; which has been called, from the inventor, the Torricellian vacuum.

It was, however, some time after this experiment had been made, and even after it had been universally agreed that the suspension of the mercury was owing to the weight of the atmosphere, before it was discovered that the column of mercury varied in height, and consequently that the pressure of the air was different at different times.

This phenomenon was, however, too remarkable to be long unobserved. It was impossible to avoid observing also, that the changes in the height of the mercury were accompanied, or very quickly succeeded, by alterations in the weather. Hence the instrument obtained the name of weather-glass; and from its also measuring the weight of the atmosphere, it is called the barometer. It is merely a tube filled with mercury, and inverted into a bason of the same, having a scale fixed at the top to ascertain the rising and falling of the mercury, by the changes in the weight of the atmosphere. A more particular account of the construction and use of this instrument is given under BAROMETER.

These effects arising from the weight and pressure of the atmosphere, have been absurdly attributed to suction; a word which ought to be exploded, as it conveys a false notion of the cause of these and similar phenomena. To prove that an exhausted receiver is held down by the pressure of the atmosphere, take one open at top, and ground quite flat, as A fig. 3, and covered with a brass plate B, which has a brass rod passing through it, working in a collar of leather, so as to be air-tight; to this rod suspend a small receiver within the large one, a little way from the bottom; place the receiver A upon the pump-plate, and exhaust it: it will now be fixed fast down; but the small receiver may be pulled up or down with perfect ease, as it is itself exhausted, and all the air which surrounded it removed, consequently it cannot be exposed to any pressure; then let the small one down upon the plate, but not over the hole by which the air is extracted, and re-admit the air into the large receiver, which may then be removed; it will be found that the small one, being itself exhausted, it held down fast by the air, which is now admitted round the outside. If the large receiver is again put over it and exhausted, the small one will be at liberty; and so on, as often as the experiment is repeated.

A square column of quicksilver twenty-nine and a half inches high, and an inch thick, weighs just fifteen pounds, consequently, the air presses with a weight equal to fifteen pounds upon every square inch of the earth's surface: and 144 times as much, or 2160 pounds, upon every square foot.

The earth's surface contains in round numbers, 200,000,000 square miles; and as every square mile contains 27,876,400 square feet, there must be 5,575,080,000,000,000 square feet on the earth's surface; which number multiplied by 2160 pounds (the pressure on each square foot), gives 12,043,468,800,000,000,000 pounds for the pressure, or whole weight, of the atmosphere.

Reckoning the surface of a middle-sized man to be about 14 square feet, he sustains a pressure from the air equal to 30,240 pounds Troy, or 11 tons 2 cwt. and 18½ lbs. It may be asked, how it happens that we are not sensible of so great a pressure? The reason is, that such pressures only are perceived by us, as move our fibres, and put them out of their natural situations. Now the pressure of the air being equal on all parts of the body, it cannot possibly displace any of the fibres, but on the contrary, braces, and keeps them all in their relative situations. But if the pressure is removed from any particular part, the pressure on the neighbouring parts immediately becomes sensible. Thus, if you take a receiver open at the top, and cover it with your hand, upon exhausting the receiver, and so taking off the pressure from the palm of the hand, you will feel it pressed down by an immense weight, so as to give pain that would be insupportable, and endanger the breaking of your hand.

If the top of the receiver is covered by a piece of flat glass, upon exhausting it, the glass will be broken to pieces by the incumbent weight; and this would happen to the receiver itself, but for the arched top, that resists the weight much more than a flat surface.

This experiment may be varied, by tying a piece of wet bladder over the open mouth of the receiver, and leaving it to dry till it becomes as tight as a drum. Upon exhausting the receiver, you will perceive the bladder rendered concave, and it will yield more and more, until it breaks with a loud report, which is occasioned by the air striking forcibly against the inside of the receiver, upon being re-admitted.

Air is one of the most elastic bodies in nature; that is, it is easily compressed into less compass, and when the pressure is removed, it immediately regains its former bulk.

Let mercury be poured into a bent tube ABCD (fig. 4,) open at both ends, to a small height as BC; then stopping the end D with a cork, or otherwise, air-tight, measure the length of confined air DC, and pour mercury into the other leg AB, till the height above the surface of that in CD is equal to the height at which it stands in the barometer at the time. Then it is plain, that the air in the shorter leg will be compressed with a force twice as great as at first, when it possessed the whole space CD; for then it was compressed only with the weight of the atmosphere, but now it is compressed by that weight, and the additional equal weight of the column of mercury. The surface of the mercury will now be at E; and it will be found, upon measuring it, that the space DE, into which the air is compressed, is just half the former CD. If another column of mercury was added, equal to the former, it would be reduced into one-third of the space it formerly occupied.

Hence the density of the air is proportional to the force that compresses it.

As all the parts of the atmosphere gravitate, or press upon each other, it is easy to conceive, that the air next the surface of the earth is more compressed and denser than what it is at some height above it; in the same manner as if wool was thrown into a deep pit until it reached the top. The wool at the bottom having all the weight of what was above it, would be squeezed into a less compass; the layer, or stratum above it, would not be pressed quite so much, the one above that still less, and so on; till the upper one, having no weight over it, would be in its natural state. This is the case with the air, or atmosphere, that surrounds our earth, and accompanies it in its motion round the sun. On the tops of lofty buildings, but still more on those of mountains, the air is found to be considerably less dense than at the level of the sea.

The height of the atmosphere has never yet been exactly ascertained; indeed, on account of its great elasticity, it may extend to an immense distance, becoming, however, rarer, in proportion to its distance from the earth.

It is observed, that at a greater height than forty-five miles, it does not refract the rays of light from the sun; and this is usually considered as the limit of the atmosphere. In a rarer state, however, it may extend much farther. And this is by some thought to be the case, from the appearance of certain meteors which have been reckoned to be 70 or 80 miles distant.

Dr. Cotes has demonstrated, that if altitudes in the air are taken in arithmetical proportion, the rarity of the air will be in geometrical proportion. For instance,

At the altitude of	miles above the surface of the earth, the air is	times thinner and lighter than at earth's surface.

And hence it is easy to prove by calculation, that a cubic inch of such air as we breathe, would be so much rarefied at the altitude of 500 miles, that it would fill a sphere equal in diameter to the orbit of Saturn.

The elastic power of the air is always equivalent to the force which compresses it: for if it was less, it would yield to the pressure, and be more compressed; was it greater, it would not be so much reduced; for action and re-action are always equal; so that the elastic force of any small portion of the air we breathe, is equal to the weight of the incumbent part of the atmosphere; that weight being the force which confines it to the dimensions it possesses.

To prove this by an experiment, pour some quicksilver into the small bottle A (fig. 5.) and screw the brass collar *c* of the tube BC into the brass neck of the bottle, and the lower end of the tube will be immersed into the quicksilver, so that the air above the quicksilver in the bottle will be confined there. This tube is open at top, and is covered by the receiver G, and large tube EF; which tube is fixed by brass collars to the receiver, and is closed at top. This preparation being made, exhaust the air out of the receiver G, and its tube, by putting it upon the plate of the air-pump, and the air will, by the same means, be exhausted out of the inner tube BC, through its open top at C. As the receiver and tubes are exhausting, the air that is confined in the glass bottle A, will press so by its spring, as to raise the quicksilver in the inner tube to the same height as it stands at in the barometer.

Miscellaneous experiments.

There is a little machine, consisting of two mills, *a* and *b*, which are of equal weights, independant of each other, and turn equally free on their axles in the frame. Each mill has four thin arms or sails, (fig. 6.) fixed into the axis: those of the mill *a*, have their planes at right angles to its axis, and those of *b* have their planes parallel to it. As the mill *a* therefore turns round in common air, it is but little resisted by it, because its sails cut the air with their thin edges; but the mill *b* is much resisted, because the broad side of its sails moves against the air when it turns round. In each axle is a fine pin near the middle of the frame, which goes quite through the axle, and stands out a little on each side of it: under these pins a slider may be made to bear, and so hinder the mills from going, when a strong spring is set or bent against the opposite ends of the pins.

Having set this machine upon the pump-plate, fig. 1. draw up the slider to the pins on one side, and set the spring at bend on the opposite ends of the pins; then push down the slider, and the spring acting equally strong upon each mill, will set them both going with equal forces and velocities; but the mill *a* will run much longer than the mill *b*, because the air makes much less resistance against the edges of its sails than against the sides of the sails of *b*.

Draw up the slider again, and set the spring upon the pins as before; then cover the machine with the receiver upon the pump-plate: and having exhausted the receiver of air, push down the wire (through the collar of leathers in the neck) upon the slider, which will disengage it from the pins, and allow the mills to turn round by the impulse of the spring; and as there is no air in the receiver to make any sensible resistance against them, they will both move a considerable time longer than they did in the open air, and the moment that one stops the other will do so too. This shews that air resists bodies in motion; and that equal bodies meet with different degrees of resistance, according as they present greater or less surfaces to the air.

Take a tall receiver A, covered at top by a brass plate, through which works a rod in a collar of leathers, (fig. 7.) and to the bottom of which there is a particular contrivance for supporting a guinea and a feather, and for letting them drop at the same instant. If they are let fall while the receiver is full of air, the guinea will fall much quicker than the feather; but if the receiver is first exhausted, it will be found that they both arrive at the bottom at the same instant: which proves that all bodies would fall to the ground with the same velocity, if it was not for the resistance of the air, which impedes most of the motion of those bodies that have the least momentum. In this experiment the observers ought not to look at the top, but at the bottom of the receiver; otherwise, on account of the quickness of their motion, they will not be able to see whether the guinea and feather fall at the same instant.

3. Take a receiver, having a brass cap fitted to the top with a hole in it; fit one end of a dry hazel-branch about an inch long, tight into the hole, and the other end tight into a hole quite through the bottom of a small wooden cup; then pour some quicksilver into the cup, and exhaust the receiver of air; and the pressure of the outward air on the surface of the quicksilver, will force it through the pores of the hazel, whence it will descend in a beautiful shower, into a glass cup placed under the receiver to catch it.

Put a wire through the collar of leathers on the top of the receiver, and fix a bit of dry wood on the end of the wire within the receiver; then exhaust the air, and push the wire down, so as to immerse the wood into a jar of quicksilver on the pump-plate; this done, let in the air; and upon taking the wood out of the jar, and splitting it, its pores will be found full of quicksilver, which the force of the air, upon being let into the quicksilver, drove into the wood.

Join the two brass hemispherical cups A and B together (fig. 8,) with a wet leather between them, having a hole in the middle of it; then having screwed off the handle at C, put both the hemispheres together and screw them into the pump-plate, and turn the cock E, so that the pipe may be open all the way into the cavity of the hemispheres; then exhaust the air out of them, and turn the cock; unscrew the hemispheres from the pump, and having put on the handle C, let two strong men try to pull the hemispheres asunder by the rings, which they will find hard to do; for if the diameter of the hemispheres is four inches, they will be pressed together by the external air with a force equal to 190 pounds; and to shew that it is the pressure of the air that keeps them together, hang them by either of the rings upon the hook of the wire in the receiver A (fig. 3.) and, upon exhausting the air out of the receiver, they will fall asunder of themselves.

Screw the end A of the brass pipe AB (fig. 9.) into the pump-plate, and turn the cock *e* until the pipe is open; then put a wet leather on the plate *c a*, fixed on the pipe, and cover it with the tall receiver GH, which is close at top; then exhaust the air out of the receiver, and turn the cock *e* to keep it out; which done, unscrew the pipe from the pump, and set its end A into a bason of water, and turn the cock *e* to open the pipe; on which, as there is no air in the receiver, the pressure of the atmosphere on the water in the bason will drive the water forcibly through the pipe, and make it play up in a jet to the top of the receiver.

Set a square phial upon the pump-plate, and having covered it with a wire cage, put a close receiver over it, and exhaust the air out of the receiver; in doing which, the air will also make its way out of the phial, through a small valve in its neck. When the air is exhausted, turn the cock below the plate to re-admit the air into the receiver; and as it cannot get into the phial again, because of the valve, the phial will be broken into some thousands of pieces by the pressure of the air upon it. Had the phial been of a round form, it would have sustained this pressure like an arch, without breaking; but as its sides are flat it cannot.

To shew the elasticity or spring of the air: tie up a very small quantity of air in a bladder, and put it under the receiver; then exhaust the air out of the receiver, and the air which is confined in the bladder (having nothing to act against it) will expand by the force of its spring, so as to fill the bladder completely. But upon letting the air into the receiver again, it will overpower that in the bladder, and press its sides close together.

If the bladder so tied up is put into a wooden box, and has twenty or thirty pounds weight of lead placed upon it, and the box is covered with a close receiver; upon exhausting the air out of the receiver, that which is confined in the bladder will expand itself so as to raise up all the lead by the force of its spring.

Screw the pipe AB (fig. 9,) into the pump-plate; place the tall receiver GH upon the plate *c a*, as before, and exhaust the air out of the receiver; then turn the cock *e* to keep out the air, unscrew the pipe from the pump, and screw it into the mouth of the copper vessel C (fig. 10.), the vessel having been first about half filled with water. Then open the cock *e*; and the spring of the air which is confined in the copper vessel will force the water up through the pipe AB in a jet into the exhausted receiver, as strongly as it did by its pressure on the surface of the water.

If a rat, mouse, or bird, is put under a receiver, and the air is exhausted, the animal will be at first oppressed as with a great weight, then grow convulsed, and at last expire in all the agonies of a most bitter and cruel death. But as this experiment is too shocking to most spectators, it is common to substitute a machine called the lungs-glass in place of the animal.

If a butterfly is suspended in a receiver, by a fine thread tied to one of its horns, it will fly about in the receiver as long as it continues full of air; but if the air is exhausted, though the animal will not die, and will continue to flutter its wings, it cannot remove itself from the place where it hangs, in the middle of the receiver, until the air is let in again, and then the animal will fly about as before.

Put a cork into a square phial, and fix it in with wax or cement; and put the phial on the pump-plate with the wire cage, and cover it with a close receiver; then exhaust the air out of the receiver, and the air that was corked up in the phial will break it outwards by the force of its spring, because there is no air left on the outside of the phial to act against that within it.

Put a shrivelled apple under a close receiver, and exhaust the air; the spring of air within the apple will plump it out, so as to cause all the wrinkles to disappear; but upon letting the air into the receiver again, to press upon the apple, it will instantly return to its former decayed and shrivelled state.

Take a fresh egg, and cut off a little of the shell and film from its smallest end, then put the egg under a receiver, and pump out the air; upon which all the contents of the egg will be forced out into the receiver, by the expansion of a small bubble of air contained in the great end, between the shell and film.

Put some warm beer into a glass, and having set it on the pump, cover it with a close receiver, and then exhaust the air. Whilst this is doing, and the pressure more and more taken off from the beer in the glass, the air in it will expand itself, and rise up in innummerable bubbles to the surface of the beer; and thence it will be taken away with the other air in the receiver. When the receiver is nearly exhausted, the air in the beer, which could not disentangle itself quick enough to get off with the rest, will now expand itself so, as to cause the beer to have all the appearance of boiling; and the greatest part of it will go over the glass.

Put some water into a glass, and a bit of dry wainscot or other wood into the water; then cover the glass with a close receiver, and exhaust the air; upon which the air in the wood, having liberty to expand itself, will come out plentifully, and make all the water to bubble about the wood, especially about the ends, because the pores lie lengthwise. A cubic inch of dry wainscot has so much air in it that it will continue bubbling for near half an hour.

Let a large piece of cork be suspended by a thread at one end of a balance, and counterpoised by a leaden weight, suspended in the same manner, at the other. Let this balance be hung to the inside of the top of a large receiver; which being set on the pump, and the air exhausted, the cork will preponderate, and shew itself to be heavier than the lead; but upon letting in the air again the equilibrium will be restored. The reason of this is, that since the air is a fluid, and all bodies lose as much of their absolute weight in it as is equal to the weight of their bulk of the fluid, the cork being the larger body, loses more of its real weight than the lead does; and therefore must in fact be heavier, to balance it under the disadvantage of losing some of its weight; which disadvantage being taken off by removing the air, the bodies then gravitate according to their real quantities of matter, and the cork which balanced the lead in air, shews itself to be heavier when in vacuo.

Set a lighted candle upon the pump, and cover it with a tall receiver. If the receiver holds a gallon, the candle will burn a minute; and then, after having gradually decayed from the first instant, it will go out, which shews that a constant supply of fresh air is as necessary to feed flame, as animal life.

The moment when the candle goes out, the smoke will be seen to ascend to the top of the receiver, and there it will form a sort of cloud; but upon exhausting the air, the smoke will fall down to the bottom of the receiver, and leave it as clear at the top as it was before it was set upon the pump. This shews that smoke does not ascend on account of its being positively light, but because it is lighter than air; and its falling to the bottom when the air is taken away, shews that it is not destitute of weight. So most sorts of wood ascend or swim in water; and yet there are none who doubt of the wood's having gravity or weight.

Set a bell on the pump-plate, having a contrivance so as to ring it at pleasure, and cover it with a receiver; then make the clapper strike against the bell, and the sound will be very well heard; but exhaust the receiver of air, and then, if the clapper is made to strike ever so hard against the bell, it will make no sound; which shews that air is absolutely necessary for the propagation of sound.

Of condensed air. It has been shewn, that air can be rarefied, or made to expand: we now proceed to shew that it can also be condensed, or pressed into less space than it generally occupies. The instrument used for this purpose is called a condenser.

Fig. 12, represents a machine of this kind; it consists of a brass barrel containing a piston, which has a valve opening downwards; so that as the piston is raised, the air passes through the valve; but as the piston is pushed down, the air cannot return, and is therefore forced through a valve at the bottom of the barrel, that allows it to pass through into the receiver B, but prevents it from returning. Thus, at every stroke of the piston, more air is thrown into the receiver, which is of very thick and strong glass. The receiver is held down upon the plate C by the cross piece D, and the screws EF. The air is let out of the receiver by the cock G, which communicates with it.

A great variety of experiments may be performed by means of condensed air, a few of which we shall here enumerate.

The sound of a bell is much louder in condensed than in common air.

A phial that would bear the pressure of the common atmosphere, when the air is exhausted from the inside, will be broken by condensing the air round it.

A very beautiful fountain may be made by condensed air. Procure a strong copper vessel, fig. 13, having a tube that screws into the neck of it so as to be air-tight, and long enough to reach to near the bottom. Having poured a quantity of water into the vessel, but not enough to fill it, and screwed in the tube, adapt to it a condensing syringe, and condense the air in the vessel; shut the stop-cock, and unscrew the syringe; then, on opening the stop-cock, the air acting upon the water in the vessel, will force it out into a jet of very great height. A number of different kinds of jets may be screwed on the tube, such as stars, wheels, &c. forming a very pleasing appearance.

Dr. Hook invented the gage, or instrument for measuring the degree of rarefaction, or exhaustion, produced in the receiver, and which is a necessary appendage to the air-pump. If a barometer is included beneath the receiver, the mercury will stand at the same height as in the open air; but when the receiver begins to be exhausted, the mercury will descend, and rest at a height which is, in proportion to its former height, as the spring of the air remaining in the receiver, to its spring before exhaustion. Thus, if the height of the mercury, after exhaustion, is the thousandth part of what it was before, we say that the air in the receiver is rarefied 1000 times. On account of the inconvenience of including a barometer in a receiver, a tube, of six or eight inches in length, is filled with mercury, and inverted in the same manner as the barometer. This being included, answers the same purpose, with no other difference, than that the mercury does not begin to descend till about three-fourths of the air is exhausted; it is called the short barometer-gage. This is generally placed detached, but communicating with the receiver by a tube concealed in the frame, as is represented at fig. 1. Others place a tube of a greater length than the barometer, with its lower end in a vessel of mercury, exposed to the pressure of the air, while its upper end communicates with the receiver. Here the mercury rises as the exhaustion proceeds, and the pressure of its remaining air is shewn by the difference between the height and that of a barometer in the room: this is called the long barometer-gage.

These gages are not often constructed so as to answer the purpose of shewing great degrees of exhaustion; for the mercury, though at first boiled to clear it of the air and moisture that adhere to it, and render it sensibly lighter, gradually becomes again contaminated by exposure to the air in the bason of either gage. They cannot, therefore, in strictness, be compared to a good barometer, in which this does not happen. If the tubes of the gages are less than half an inch in diameter, the mercury will be sensibly repelled downwards, so as to require a correction for the long gage when compared with a barometer whose tube is of a different bore, and to render the short gage useless in great exhaustions.

Thus, for example, if the short gage has a tube of one-tenth of an inch in diameter, the mercury will fall to the level of the bason, when the exhaustion is 150 times, and will stand below the level for all greater degrees of rarefaction. These difficulties may be all removed, by making the short gage in the form of an inverted syphon, with one leg open, and the other hermetically sealed. It must be confessed, however, that it is difficult to boil the mercury in these.

In using the air-pump, every substance containing moisture should be removed from the pump-plate, as water assumes the form of an elastic vapour when the pressure of the atmosphere is taken away. The receivers used formerly to be placed upon the pump-plate, on leathers soaked in water or oil; but Mr. Nairne discovered that an elastic vapour arose from this, that considerably affected the gage, and prevented it from shewing the real degree of rarefaction of the air. Instead of the leathers to place under the receiver, the best way is, to have the pump-plate ground perfectly flat, and also the edge of the receiver, which should be rubbed with a little hog's-lard or soft pomatum, which will perfectly exclude the air, and will not afford any moisture. The pump-plate and the receiver should be wiped very clean.

When leathers are used, the barometer-gages will not shew the degree of rarefaction of the air; which, however, may be ascertained by a gage invented by Mr. Smeaton, and called, from its form, the pear-gage. It consists of a glass vessel, in the form of a pear, fig. 11, and sufficient to hold about half a pound of mercury: it is open at one end, and at the other end is a tube hermetically closed at top. The tube is graduated, so as to represent proportionate parts of the whole capacity. This gage, during the exhaustion of the receiver, is suspended in it by a slip of wire, over a cistern of mercury, placed also in the receiver. When the pump is worked as much as is thought necessary, the gage is let down into the mercury, and the air re-admitted. The mercury will immediately rise in the gage: but if any air remained in the receiver, a certain portion of it would be in the gage; and as it would occupy the top of the tube above the mercury, it would shew by its size the degree of exhaustion; for the bubble of air would be to the whole contents of the gage, as the quantity of air in the exhausted receiver would to an equal volume of the common atmospheric air. If the receiver contained any elastic vapour generated during the rarefaction, it would be condensed upon the re-admission of the atmospheric air, as it cannot subsist in the usual pressure. The pear-gage, therefore, shews the true quantity of atmospheric air left in the receiver. Hence it will sometimes indicate that all the permanent air is exhausted from the receiver, except about $\frac{1}{100000}$ part, when the other gages do not shew a degree of exhaustion of more than 200 times, and sometimes much less.

Particular care should be taken, after making any experiments where vapour has been generated, to clear the pump of it, before any other experiments are attempted; for the vapour remains not only in the receiver, but also in the tubes and barrels of the pump, and will, when the air is again rarefied, expand as before. To clear the pump of this vapour, take a large receiver, and wiping it very dry, exhaust it as far as possible. The expansible vapour which remained in the barrels and the pipes, will now be diffused through the receiver; and, consequently, will be as much rarer than it was before, as the aggregate capacity of the receiver is larger than that of the pump and pipes. If the receiver is large, one exhaustion will be sufficient to clear the pump so far, that what remains can be of no consequence. If the receiver is small, the operation should be repeated two or three times.

In all mercurial experiments with the air-pump, a short pipe must be screwed into the hole of the pump-plate, so as to rise above it about half an inch, to prevent the quicksilver from getting into the air-pipe and barrels, in case any should accidentally be spilt over the jar; for if it gets into the barrels, it spoils them, by loosening the solder, and corroding the brass.

With respect to the leathers, if your pump-plate is not ground, they are absolutely necessary; they should be previously soaked in oil from which the moisture has been expelled by boiling, or hog's-lard with a little bee's-wax, which gives a clamminess very proper for the purpose.

It is evident, that the vacuum in the receiver of the air-pump, can never be perfect, that is, the air can never be entirely exhausted; for it is the spring of the air in the receiver, that raises the valve, and forces its way into the barrel; and the barrel at each suction can only take away a certain part of the remaining air, which is in proportion to the quantity before the stroke, as the capacity of the barrel is to that of the barrel and receiver added together.

This, however, is an imperfection that is seldom of much consequence in practice, because most air-pumps, at a certain period of the exhaustion, cease to act, on account of their imperfect construction; for the valves usually consist of a piece of oiled bladder tied over a hole, so that the air is at liberty to pass by lifting up the bladder, but cannot return again; and thus there will unavoidably be a small space left between the lower valve and the piston, when down.

Now, it will happen, when the air in the receiver is very rare, that its spring will not be strong enough to overcome the adhesion of the bladder forming the lower valve, which consequently will remain shut and the exhaustion cannot proceed. Or, before this period, it may happen, that the air between the valves when the piston is up, may be so small as to lie in the space between the two valves when the piston is down, without being sufficiently condensed for its spring to overcome the adhesion of the bladder forming the upper valve, and the weight of the atmosphere that presses it: in this case, the upper valve will remain shut, and the exhaustion cannot proceed.

Various modern improvements in the air-pump, obviate these inconveniences in a great degree. Mr. Smeaton, a very ingenious mechanic, enlarged the size of the lower valve; and, to strengthen it, supported it on a brass grating, resembling a honey-comb. This allowed the valve to rise more easily. He also covered the top of the barrel, making the piston-rod work through a collar of leathers, by which he took off the pressure of the atmosphere from the piston-valve, which acted against the rarefied air in the receiver. Pumps on this construction have been made by Nairne, and other artists in London, and have answered extremely well.

The air-gun. This pneumatical instrument is an ingenious contrivance, which will drive a bullet with great violence, by means of condensed air, forced into an iron ball by a condenser. Fig. 14. represents the condenser for forcing the air into the ball. At the end *a* of this instrument is a male screw, on which the hollow ball *b* is screwed, in order to be filled with condensed air. In the inside of this ball is a valve, to hinder the air after it is injected from making its escape, until it is forced open by a pin, against which the hammer of the lock strikes; which then lets out as much air as will drive a ball with considerable force to a great distance.

When you condense the air in the ball, place your feet on the iron cross *h h*, to which the piston-rod *d* is fixed; then lift up the barrel *e a*, by the handles *i i*, until the end of the piston is brought between *e* and *c*; the barrel *a c* will then be filled with air through the hole *e*. Then thrust down the barrel *a c* by the handles *i i*, until the piston *e* joins with the neck of the iron ball at *a*: the air, being thus condensed between *e* and *a*, will force open the valve in the ball; and when the handles *i i* are lifted up again, the valve will close, and keep in the air; so by rapidly continuing the stroke up and down, the ball will presently be filled; after which, unscrew the ball off the condenser, and screw it upon another male screw, which is connected with the barrel, and goes through the stock of the gun, as represented fig. 15. Twelve dwts. of air have been injected into a ball of 3.75 inches diameter, which has discharged 15 bullets with considerable force.

There are many contrivances in constructing air-guns; some have a small barrel contained within a large one, and the space between the two barrels serves for the reception of condensed air. In this sort, a valve is fixed at *a*, (fig. 15,) with a condenser fixed to the barrel, and continued through the butt-end to *c*, where the piston-rod may be always left in. Place your feet on the pin, and the whole gun serves instead of the handles *i i* (fig. 14.) to condense the air in the barrel.

Fig. 17. is a section of the gun, by which the principle of its action may be fully understood: the inside barrel K is of a small bore from which the bullets are shot, and a larger barrel CDSR is on the outside of it. In the stock of the gun is a syringe S, which forces in the air through the valve EP into the cavity between the two barrels. The ball K is put into its place in the same way as in another gun. There is a valve at SL, which, being opened by the trigger O, permits the air to come behind the bullet, so as to drive it out with great force. If the valve is suddenly opened and closed, one charge of condensed air may make several discharges of bullets; because only part of the air will go out at a time, and a fresh bullet may be put into the place K.

The magazine air-gun differs from the common one, only by having a serpentine barrel, which contains ten or twelve balls; these are brought into the shooting barrel successively, by means of a lever; and they may be discharged so fast as to be nearly of the same use as so many different guns.

Fig. 18. shews a section of the gun, or at least, as much of it as is necessary to give a complete idea of the whole. AE is part of the stock; G the end of the injection syringe, with its valve H, opening into the cavity FF between the barrels. KK is the small or shooting barrel, which receives the bullets, one at a time, from the magazine ED, which is a serpentine cavity, where the bullets are lodged and closed at the end D; the circular part is the key of a cock, having a cylindrical hole, IK, through it, equal to the bore of the small barrel, and forming a part of it. When the lock is taken off, the several parts come in view, by means of which the discharge is made, by pushing up the pin P *p*, which rises and opens a valve, V, to let in the air against the bullet I, from the cavity FF, which valve is immediately shut down again by means of a long spring of brass, NN. This valve V, being a conical piece of brass, ground very true, will be sufficient to confine the air. To make a discharge, pull the trigger ZZ, which throws up the seer *y x*, and disengages it from the notch *x*, upon which the strong spring WW moves the tumbler T, to which the cock is fixed. The end *u* of this tumbler, bears down the end *v* of the tumbling lever R, which by its other end *m* raises the flat end, *l*, of the horizontal lever Q, by which means the pin P *p* is pushed up, and opening the valve V, discharges the bullet. To bring another bullet instantly to succeed to I, there is a part H called the hammer, represented in fig. 19. which turns the cock so as to place the cylindric bore of the key I *k* in any situation required. Thus when the bullet is in the gun, the bore of the key coincides with that of the barrel KK; but when it is discharged, the hammer H is instantly brought down to shut the pan of the gun; by which motion the bore of the key is turned into the situation *i k*, so as to coincide with the orifice of the magazine; and upon lifting the gun upright, the ball next the key tumbles into its cavity, and falling behind two small springs *s s* fig. 18. is by them detained.

American air-pump. It would not come within the limits of this work, to enumerate all the improvements, and different modes of construction, used in this instrument. The latest are the air-pumps made by Haas and Hurter, Cuthbertson, and Prince, each of which has particular advantages.

We shall however give a perspective view of the air-pump invented by Mr. Cuthbertson, which is so excellent in its structure, and so powerful in its effects, as to demand in the present improved state of science, a particular notice and description. See Plate II. Pneumatics, Cuthbertson's air-pump. The two principal gages of this pump are screwed in their places; but it is not necessary that these should be used together, except in experiments that require great nicety, and very exact exhaustion. In common cases either of them may be taken away, and a stop-screw put into its place. When the pear-gage, which has been already described, is used, a small round plate, large enough for the receiver to stand upon, must first be screwed into a hole at *a*, but when this gage is not used this hole must be closed with a stop-screw. When all these gages are used, and the receiver is exhausted, the stop-screw B, at the bottom of the pump, must be unscrewed, to admit the air into the receiver; but when the gages are not all used, the stop-screw at *a*, or either of the others in the place of gages, may be unscrewed for this purpose. The mechanism and object of the barrels D, D, the racks C, C, the plate G, and handle H, will be easily understood from the figure. CD fig. 2. represents a section of one of the barrels of the pump, F the collar of leathers which renders it air-tight, G a hollow cylindrical vessel to contain oil; R is also an oil-vessel, which receives the oil that is driven with air through the hole *a a*, when the piston is drawn upwards; and when this falls, the oil is carried over with the air along the tube T, into the oil-vessel G: *c c* is a wire which is driven upwards from the hole *a a* by the passage of the air; and as soon as this is escaped, falls down again by its own weight, shuts up the hole, and prevents any air from returning by that way into the barrel; at *d d* are fixed two pieces of brass, to keep the wire *c c* in such a direction as may preserve the hole air-tight. H is a cylindrical wire, which carries the piston I, and is made hollow to receive a long wire *q q*, that opens and closes the hole L, which forms the communication with the receiver standing on the plate: *m* is part of a pipe, one end of which is screwed into the wire *q q*, that opens and shuts the hole L; and upon the other end O, is screwed a nut, which, stopping in the smaller part of the hole, prevents the wire from being lifted too high. This wire and screw are more clearly seen in fig. 3.; they slide through a collar of leathers *r r* (see figs. 3 and 5,) in the middle of the piston. Figures 5 and 6, are the two main parts which compose the piston; and when the pieces in figs. 7 and 4 are added to it, the whole is represented in fig. 3. Figure 5 is a piece of brass, turned in a conical form, with a shoulder or ledge at the bottom; a long female screw is cut into it, about two-thirds of its length; and the remaining part of the hole, in which there is no screw, is about the same-sized diameter as the screw part; except a thin plate at the end, which is of a breadth exactly equal to the thickness of *q q* fig. 2. That part of the inside of the conical piece of brass, in which no thread is cut, is filled with oiled leathers with holes in them, through which *q q* can slide air-tight; there is also a male screw with a hole in it which is fitted to *q q*, and serves to press down the leathers *r r*. In fig. 6, *a a a a* is the outside of the piston, the inside of which is turned exactly to fit the outside of fig. 5; *b b* are round leathers, *c c* is a circular plate of brass of the size of the leathers, and *d d* is a screw which serves to press them down as tight as it is necessary. The male screw at the end of fig. 7, is made to fit the screw in fig. 5. If fig. 4. is put into fig. 5, and that again into fig. 6, and fig. 7 screwed into the end of fig. 5, these will compose the whole piston as represented by fig. 3. H in fig. 2, is that part to which the rack is fixed. If this, therefore, is drawn upwards, it will make fig. 5 shut close to fig. 6, and drive out the air above it; and when it is pushed downwards, it will open as far as the shoulders *a a* will allow, and suffer the air to pass through. AA fig. 8. is the receiver-plate; B is a long square piece of glass screwed to the undermost side of the plate, through which a hole is drilled, corresponding with that in the centre of the receiver-plate, and with the three female screws *b b c*.

To conceive how the rarefaction of the air is effected, suppose the piston to be at the bottom of the barrel, and a receiver to stand upon the plate; the inside of the barrel from the top of the piston to *a* is full of air, and the piston shut: when drawn upwards, by the cylindrical wire H, it will drive the air before it through the hole *a a* into the oil-vessel R, and out into the atmosphere by the tube T. The piston will then be at the top of the barrel at *a*, and the wire *q q* will stand nearly as it is represented in the figure, just raised from the tube L, and prevented from rising higher by means of the nut *o*. While the piston is moved upwards, the air will expand in the receiver, and be driven along the bent tube *m* into the inside of the barrel. Thus the barrel will be filled with air, which, as the piston rises, will be rarefied in proportion as the capacity of the receiver, pipes, and barrel, is to the capacity of the barrel alone. When the piston is moved downwards again by H, it will force the conical part fig. 5, out of the hollow part fig. 6, as far as the shoulders *a a.*; fig. 3. will rest upon *a a*, fig. 6, which will then be so far open as to permit the air to pass freely through it, while at the same time the end *q q* is forced against the top of the hole, and closes it in order to prevent any air from returning into the receiver. Thus the piston, while moved downwards, suffers the air to pass out between the figs. 6 and 5, and when it is at the bottom of the barrel, will have the column of the air above it; and, consequently, when drawn upwards, it will shut and drive out this air, and by opening the hole L, give a free passage to more air from the receiver. This process being continued, the air will be exhausted out of the receiver as far as the expansive power will permit: for in this instrument there are no valves, as in common air-pumps, to be forced open by the air in the receiver, which, when its elasticity is diminished, it becomes unable to effect; nor is there any thing to prevent the air from expanding to the greatest degree.

The oil-vessel G, fig. 2, must be always kept about half-full of oil; and when it has stood long without using, it will be right to draw a table-spoonful or more through it, by pouring it into the hole *a*, in the middle of the receiver-plate, fig. 1. when the piston is at the bottom of the barrel; then by moving the winch H backwards and forwards, the oil will be drawn through all the parts of the machine, and the superfluous part will be forced out through the tube T, into the oil-vessel G. Near the top of the cylindrical wire H, fig. 2, is a square hole, which is intended to let in some of the oil from the vessel G, that the oiled leathers, through which the wire *q q* slides, may always be duly supplied with it. Fig. 9. is a representation of a condensing-apparatus used with this pump.

Mr. Cuthbertson has by many experiments shewn the great powers of exhaustion of which this pump is capable. With the double syphon-gage, and also with the long gage, compared with an attached barometer in which the mercury has been well boiled, the difference between the heights of the mercurial column proved no more than $\frac{1}{40}$ of an inch: the barometer standing at 30 inches, which is an exhaustion of 1200 times; and on some occasions, when the air was very dry, he observed the difference to be as low as $\frac{1}{100}$ of an inch, which gives more than double that degree of rarefaction.

We must not omit the American air-pump, invented by Mr. Prince, who first took away the valves, which were long known to prevent the air from entering the barrel above the piston. His next attempt was to expel the air more perfectly out of the barrel than Mr. Smeaton had done, by making a better vacuum between the piston and the top plate, so that more of the air might be allowed to expand itself into the barrel from the receiver. Mr. Prince also contrived to connect the valves on the top plate with the receiver occasionally by means of a pipe and cock, by the turning of which the machine might be made to exhaust or condense at pleasure. In order to remove the pressure of the atmosphere from the valve on the top plate, so that this valve might open as easily as the piston-valve, he connected with the duct on the bottom piece, which conveys the air from the valves to the cock, a small pump of the same construction as the large one, having the barrel opening into the cistern; the piston-rod, which is solid, moving through a collar of leathers, and a valve near the top, through which the air is forced into the atmosphere. This pump with one barrel is called the valve-pump; its chief use being to rarefy the air above the valves, or to remove the weight of the atmosphere from them. When this valve-pump is used, the passage through the cock is shut up; and, therefore, instead of placing three ducts at equal distances round the cock in the manner of Mr. Smeaton's, Mr. Prince divided the whole into five equal parts, leaving the distance of one-fifth part between the ducts leading from the cistern and valves to the cock, and two-fifths between each of these and the one leading from the cock to the receiver. By this adjustment, when the communication is open between the receiver and the valves for condensation, the other hole through the cock opens the cistern to the atmosphere; but when the communication is made between the cisterns and the receiver for exhaustion, a solid part of the key comes against the duct leading to the valve and shuts it up, and the air which is forced out of the barrel, passes through the atmosphere into the valve-pump; for the valve of the small pump may be kept open while the great one is worked.

Upon this construction, the pump with two barrels may be made like the common pump, which cannot be conveniently done where the lower valve is retained. In this pump, the pistons do not move the whole length of the barrels; an horizontal section being made in them a little more than half-way from the bottom, where the top plates are inserted. The pump is thus made more convenient and simple; as the head of it is brought down upon the top of the barrels, in the same manner as in the common air-pump. The barrels also stand upon the same plane with the receiver-plate, and this plane is raised high enough to admit the common gage of 32 or 33 inches to stand under it without inconvenience in working the pump; as the winch moves through a less portion of an arch at each stroke, than it would do if the pistons moved through the whole length of the barrels.

A gage for measuring the degree of condensation, having a free communication with the valves, cock, &c. is placed between the barrels in this pump; and the gage is so constructed that it will also serve to measure the rarefaction above the valves when the air is worked off by the valve-pump. It consists of a pedestal, the die of which is made of glass, which forms a cistern for the mercury; a hollow brass pillar; and glass tube hermetically sealed at one end, which moves up and down in the pillar through a collar of leathers. When the pump is used as a condenser, the degree of condensation is shewn by a scale marked on one edge of the pillar; when it is used as an exhauster, the degree of rarefaction of the air above the valves, is shewn by a scale on the other edge of the pillar. This gage will also shew, when the valves have done playing, either with the weight of the atmosphere on them or taken off, in the manner which the author has described. The degree of condensation may be also measured by the number of strokes of the winch. For the purposes of great condensation, Mr. Prince has fitted a condenser of a smaller bore than the barrel of the great pump to the cistern of the valve-pump, to be screwed on occasionally. Or, without this condenser, the valve-pump may be adapted to the purpose by being made a little larger, and by having a plate made to screw into the bottom of the cylinder, with a valve on it opening into the cistern; a hole must be made to be opened on the same occasion near the top of the cylinder, to let air in below the piston when this is drawn up above it.

The common gage, which is generally placed under the receiver-plate, is placed in the front of this pump, that it may be seen by the person who works it, and that the plate may be left free for other uses. The plate is so fixed to the pipe leading to the cock, that it may be taken off at pleasure, and used as a transferer; and it may also serve for other purposes.

The head of this pump is made whole, except a small piece on the back, where the wheel is let in; and the wheel is freed from the piston-rods by pushing it into the back part of the head, and it is kept in its place by a button screwed into the socket of the axis behind. By this apparatus, the piston-rods are dislodged from the wheel, and let down into the cisterns, when the pump is not used; and in these cisterns they may also have the advantage of being covered with oil. The principal joints of this pump are sunk into sockets, that the leathers which close them may be covered with oil to prevent leaking. The lower part of the pump is fitted with drawers to contain the necessary apparatus.

We shall close our account of the two pumps of Prince and Cuthbertson, with the following judicious remarks of Mr. Nicholson on their respective merits and imperfections: "There is no provision to open the upper fixed valve of Prince's greater barrel, except the difference between the pressures of the elastic fluid on each side of the strip of bladder; and this may reasonably be inferred to limit the power of his small pump. In Cuthbertson's pump, the same valve is exposed to the action of the atmosphere, together with that of a column of oil in the oil-vessel. The mischief in either instrument is probably trifling, but in both the valve might have been opened mechanically. If this were done, the small pump of Prince might, perhaps, be unnecessary in most states of the atmosphere. With regard to the lower valves, Cuthbertson, by an admirable display of talents as a workman, has ensured their action. Prince, on the other hand, has, by the process of reasoning, so far improved the instrument, that no valves are wanted. In this respect, he has the advantage of simplicity and cheapness with equal effect. The mechanical combination of Cuthbertson's pump, reduces the operation to one simple act of the handle; but Prince's engine requires some manipulation with regard to the play of the small pump, though this might have been remedied by a more skilful disposition of the first mover.

"The most perfect scheme for an air-pump, taking advantage of the labours of these judicious operators, seems to be that in which two pistons of the construction of Prince should work in one barrel, one piston being fixed at the lower end of the rod, and the other at the middle. The lower piston must come clear out of the barrel when down, and work air-tight through a diaphragm at an equal distance from the effective ends of the barrel. In the diaphragm must be a metallic valve of the form of Cuthbertson's lower valve, but with a short tail beneath, that it may be mechanically opened when the piston comes up. Above the diaphragm must work the other piston, similar to the first; but as it cannot quit the barrel when down, a small portion of the barrel must be enlarged just above the diaphragm, so that the leathers may be clear in that position. Lastly, the top of the barrel must be closed and fitted with a valve and oil-vessel, according to the excellent contrivance of Cuthbertson.

"If we suppose the workmanship of such a pump to leave the space between the diaphragm and lower piston, when up, equal to one-thousandth part of the space passed through by the stroke of that piston, the rarefaction produced by this part of the engine will, in theory, bear the same proportion to that of the external air; and the same supposition applied to the upper piston, would increase the effect one thousand times more; whence the rarefaction would be one million times. How far the practical effect might fall short of this, from the imperfection of workmanship, or the nature of the air, which, in high rarefactions, may not diffuse itself equally through the containing spaces, or from other, yet unobserved circumstances, cannot be deduced from mere reasoning, without experiment.

PNEUMORA, a genus of insects of the order hemiptera. The generic character is, body ovate, inflated, diaphanous; head inflected, armed with jaws; thorax convex, carinate beneath; wing-cases deflected, membranaceous; legs formed for running. The insects of this genus appear to consist of a mere hollow inflated membrane. By rubbing together their toothed legs, they make a shrill kind of noise morning and evening, and follow a light. They are so nearly allied to the cricket tribe, that Fabricius has enumerated them under the genus gryllus. There are three species.

POA, *meadow-grass*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the fourth order, gramina. The calyx is bivalved and multiflorous; the spicula or partial spike is ovate, with the valvules scarious, and a little sharp or thin on the margin. There are 71 species, most of them grasses, and very agreeable food for cattle; for one species, which grows in marshes, the cattle will frequently go so deep as to endanger their lives. This is called the aquatica, or water reed-grass. It is the largest of the British grasses, growing to the height of five or six feet. The leaves are smooth, and half an inch wide or more. The panicle is eight or ten inches long, greatly branched, and decked with numerous spicula; these are of a reddish brown colour intermixed with green, of a compressed lanceolate form, imbricated with about six flowers for the most part, but varying from five to ten. See HUSBANDRY, and Plates LXVIII. and LXIX.

POCKET, in the woollen trade, a word used to denote a larger sort of bag, in which wool is packed up to be sent from one part of the kingdom to another. The pocket contains usually twenty-five hundredweight of wool. The pocket of hops is also a small bag usually containing the best hops.

POCKET-*instruments*, in surgery. See INSTRUMENT.

PODOPHYLLUM, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 27th order rhœadeæ. The corolla has nine petals; the calyx is triphyllous; the berry unilocular, crowned with the stigma. There are two species, creeping plants of North America.

PODURA, a genus of insects of the order aptera. The generic character is, legs six, formed for running; eyes two, composed of eight; tail forked, formed for leaping, inflected; antennæ setaceous, elongated. The poduræ are small insects which, in general, are found in damp places, under stones, on the bark of trees, &c. When disturbed, they suddenly spring to a small distance by the help of a long, forked process, which is doubled under the abdomen, and which is suddenly thrown out during the act of leaping.

One of the most common of this genus is the podura aquatica of Linnæus, measuring scarcely the twelfth part of an inch in length, and entirely of a black colour. This a gregarious species, and is occasionally seen assembled in vast numbers, particularly near the brinks of ponds, covering the ground to the distance of several feet, and sometimes even the surface of the water itself. On the ground its legions, on a cursory view, have the appearance of scattered grains of gunpowder; and, if closely examined, will be found in an almost continual skipping motion.

Podura fimetaria so perfectly resembles the preceding in all respects except colour, being perfectly white, that no other specific difference can be observed. It is almost equally common in damp situations with the former.

Podura atra is of a short, subglobular shape, with lengthened antennæ: its colour is a glossy black. It is found on the bark of trees, &c.

Podura plumbea is of a blueish black or deep lead-colour, and is found in similar situations.

Podura arborea is of a lengthened form, and of a black colour, with the feet and caudal fork white. It is chiefly found on the bark of trees, among mosses, &c. There are 14 species.

POEM. See POETRY.

POETRY is that kind of literary composition which is characterised by metrical harmony. Various have been the attributes and pretensions assigned to poetry. By some it has been made to consist in fiction, by others in imitation. By one critic it has been elaborately designated as "the art of illustrating in metrical numbers every being in nature, and every object of imagination, for the delight and improvement of mankind." By a more judicious writer it is assumed to be "the language of passion, or of enlivened imagination, formed most commonly into regular numbers;" and this definition, though not perfectly correct, is, perhaps, less exceptionable than any other which has been submitted to investigation.

Poetry is commonly called an art, yet is not unfrequently classed with the sciences; a dignity perpetuated to it by traditional authority, from the early ages, when the bard was a personage sacred as the priest, and all the knowledge or the wisdom extant was enveloped in fable, or unfolded in numbers.

In the progress of society from barbarism to refinement, it was impossible that the analogies subsisting between certain operations of intellect should be overlooked; and the mythology of Greece, which embodied even the abstractions of science, gave to these metaphysical relations a personal character corresponding with the sympathies and dependances of domestic life. In these popular personifications, a remarkable predilection appears for the triple numbers. The Parcæ, the Furies, the Graces, and originally the muses, were composed of sisterly triads. In like manner, music, poetry, and painting, from the intimate connection observed between the two first of these arts, and their supposed affinity to the last, were united in the same bond of union; and the legitimacy of the relation on which this elegant allegory was founded, is yet recognized in popular language as an unequivocal and undisputed truth.

Of these kindred arts, music and poetry issued from the same woods, cherished and respected by the rudest and most uncultivated generations of men. The metre of poetry is evidently borrowed from the simple melodies of music; and it may be presumed, was produced in the first efforts to combine vocal with instrumental sounds. The ambition of the primitive poet must have been limited to that artificial modulation of language which is now considered as the least and lowest of poetical attainments, but which unquestionably forms a radical part in the constitution of poetry. The origin of painting is not equally remote. Many subordinate arts, concomitant with the progress of civilization, must have previously existed; and it is well known that poetry inspired enthusiasm and veneration, not only in the ferocious tribes of Scandinavia, but in the Hebrews and the Arabs, to whom the delineation of the human form was an art proscribed by legislative authority, or contemned by national prejudice. The first specimens of poetry could not but be rude as the society for which they were composed Alliteration appears to have been an initial character of verse; and the rudiments even of rhyme are discernible in those similar or identical terminations adopted by the Celtic and Runic bards, and exemplified in the practice of Oriental antiquity. By the agency of metre, a poetical style was gradually produced; and in the labour of balancing and adjusting his sentences, the poet insensibly acquired vigilance, discrimination, and taste. Figurative language, which is familiar to a primitive state of society, has supplied to every people some of the purest elements of poetry. But this language is not the exclusive property of the poet; it belongs to every writer of imagination; and though more essential to verse, is almost equally becoming in prose; nor would it be difficult to produce from Bacon and Jeremy Taylor in one age, from Burke and Gibbon in another, as brilliant combinations of thought as any that have been exhibited in verse.

The following passage from Shakspeare, though written in prose, is as rich in imagery as any part of his metrical compositions: "This goodly frame, the earth, seems to me a sterile promontory; this most excellent canopy, the air; this majestical roof, fretted with golden fire, why it appears no other thing to me than a foul and pestilential congregation of vapours. What a piece of work is man! How noble in reason; how infinite in faculties; in form and moving, how express and admirable; in action, how like an angel; in apprehension, how like a god!" The figures of rhetoric, therefore, (see RHETORIC,) including all the varieties of metaphor, allegory, and simile, are common to all the higher orders of literary composition; the mechanism of verse being, perhaps, the only positive line of demarcation, by which the boundaries of prose and verse are distinguished from each other.

Antient poetry.

That the higher order of poetry is not unattainable in an uncultivated age, is a truth eminently illustrated by the example of the Hebrew people. Admitting language to be, as Mr. Richardson ingeniously observes, the barometer of society, by which its comparative barbarism or civilization is indicated, it will be obvious that the bards of Sion composed their lofty songs for a primitive nation, tenacious of its customs and opinions, unenlightened by science, uncorrected by taste, and as little acquainted with the arts as the refinements of polished life.

The simplicity and energy of the Hebrew language, accorded happily with the sublime nature of sacred poetry; and to the peculiarities in its constitution it is, perhaps, owing that the primitive character of its composition is tenaciously preserved to whatever language transferred, or with whatever idioms assimilated. The musical harmony of the Hebrew language is now but imperfectly known; its prosody is, however, sufficiently understood to suggest a comparison between its rhymes, and the wild measures familiar to the Scandinavian nation. Alliteration was freely admitted in their verse, as were identical terminations and other artificial embellishments; but its distinctive feature was a symmetrical disposition of the sentences, which were cast into parallel verses of equal length, and correspondent in sense and sound: the sentiment expressed in the first distich being repeated and amplified in the second, as in the following examples: "The Lord rewardeth me according to my righteousness: according to the cleanness of my hand he hath recompensed me. The statutes of the Lord are right, rejoicing the heart: the commandment of the Lord is pure, and enlighteneth the eyes. The fear of the Lord is clean, enduring for ever: the judgments of the Lord are pure and righteous altogether." This practice, which appears to have been peculiar to the Hebrews, was derived from their rites of worship; in which the sacred hymns were chaunted by bands of singers, who alternately responded to each other.

The Hebrew bards employ few epithets: the brevity of their style renders its sublimity conspicuous; their imagery is bold and energetic; their magnificent conceptions issue from the mind in native majesty and strength; their imagination is ever rich and exuberant; and to them, metaphors spontaneously arise on every subject, in inexhaustible beauty and fertility.

Although Hebrew poetry presents nothing that in critical language can be classed with epic or dramatic composition, it affords innumerable examples of the lyric, the elegiac, and the didactic style. In the prophecies, the favourite figure is allegory: the Hebrews having, in common with other Oriental nations, a decided predilection for the parabolic species of writing. It would be injustice to the sacred bard, not to remember in what country he wrote, and with what people he lived. On examination, his images will be found to have been faithfully transcribed from nature, and beautifully to have harmonized with the scenes and manners familiar to his observation and experience; but the pure and uncorrupted theism maintained by the inspired bard, is his most exalted attribute, and is evidently the cause of his pre-eminence in sublimity over all other Oriental writers.

The Arabs were not, like the Hebrews, a stationary people, insulated from the rest of mankind. Alternately engaged in commerce and in war, their erratic chiefs visited distant regions; and in their intervals of leisure, were no less ambitious to obtain poetical distinction, than they had been to secure military fame.

Poetry, which constituted the sacred science of the Hebrews, became with the Arabs a polite accomplishment; and as the copiousness of their language supplied all the aptitudes of numbers, it is not surprizing that improvisatori bards should have been found in their deserts. The distich, and many other forms of metrical composition, adapted to familiar occasions, were of Arabian invention; and it is the plausible suggestion of sir William Jones, that rhymes were borrowed from Eastern literature by the Provençal and Castilian poets, through whose influence they were naturalized to Europe. With all the copiousness and flexibility of the Arabic, the

Persic language is found to possess an amenity and an elegance which render it eminently susceptible of poetical beauty. Its poets, like those of antient Greece, have the power of rendering language subservient to their pleasure, and of clothing original conceptions in a new-created word.

Several Arabic and Persian poems are of the epic and dramatic cast; but the compositions most inviting to the European for translation, are of an amatory, elegiac, and lyric character. In general, Oriental poetry deviates from the primitive simplicity so conspicuous in Hebrew compositions, and often degenerates into affectation and bombast. In their most admired authors indeed, a passion for the gaudy and the gorgeous is ever predominant. The magnificence of their materials is disguised by their fantastic arrangement; and the eye which has dwelt with delight on the chaste graces of classical literature, soon turns with disgust from the jewelled turban and the barbaric gold. There are, however, some passages, particularly in braminical poetry, which are perfectly simple and sublime. Of these a noble specimen is given by sir William Jones in the hymn to Narrayna.

Of classical poetry.

The germs of genius scattered through Oriental compositions with wild luxuriance, appear in classical poetry displayed in full perfection and beauty. To what causes the pre-eminence of antient Greece in this part of literature is to be attributed, it would here be futile to conjecture. From the susceptibility of his language, the poet was enabled to exhibit the same idea under a new aspect, and to give to every fluctuation of feeling a permanent expression. If the vivacity of his descriptions fascinated the imagination, his numbers dwelt with no less enchantment on the ear. The length and shortness of syllables in the Greek and Roman languages, which constituted their quantities, was determined by rules no less accurate than the notes in music; and on the proper distribution and adjustment of these quantities, the harmony of their metre depended. A stated interval of time was allowed to the pronunciation of every verse. To facilitate the labour of composition, artificial combinations of syllables by the name of feet, were invented; and by the number of these, and the quantities included in them, the character of the verse was ascertained.

To these combinations various names were given; the most important were the spondee, composed of two long syllables, and the dactyl, formed by one long and two short syllables. These were solely employed in the construction of the hexameter verse, of which an imitation has been vainly attempted in the English language. The pronunciation of the Greek and Latin languages is, indeed, almost as totally lost to us, as that of the Hebrew; but such is the exquisite mechanism of their metre, that their verses cannot be read without producing a rich and often a melodious intonation, perceptible even to the unlettered ear.

In the happy regions of Greece, it is uncertain what species of poetry was first cultivated. Fables were compositions of great antiquity; the ode formed a part of religious worship; the pastoral must have been introduced in an age sufficiently refined to relish simplicity. The immortal poems of Homer were composed at an early epoch of Grecian literature, and, as is well known, transmitted by oral tradition to a more polished age. Of this extraordinary man, so much has been said, that it would appear difficult to say any thing which should not now be trivial or impertinent. This arduous task the perseverance of modern criticism has, however, achieved; and a scholastic sect is now known to exist who would sacrilegiously remove the shrine of Homer from the temple of fame, and abandon to superstitious credulity a name sanctified by the enthusiasm and veneration of preceding ages.

It is pretended that the Iliad and Odyssey were composed at different eras, by various authors; and that these desultory tales of Troy were at length collocated and edited by some ingenious critic, who might possibly have been distinguished by the appellation of Homer. The novelty, and, perhaps, the extravagance of this hypothesis, have obtained for it partisans among those professed sceptics and segregatists who can perceive no difference between vulgar errors and popular opinions, and whose ambition it is to recede as far as possible from all participation in the sentiments or convictions of other men. It is generally admitted that the excellence in which the supposed Homer stands unrivalled, is the energy of his conceptions, which gives to his personages, his scenes, and his descriptions, a real and individual existence. With such felicity are his characters cast, that no reader of feeling can be at a loss to conceive how Achilles would look, or Nestor speak, or Ulysses act, on any imaginary occasion. The unprejudiced will decide whether such exquisite harmony of design could have been the result of chance, or whether each book had its separate Homer, or whether they were all planned and executed by one.

In lyrical composition, the most popular was the heroic ode. The name of Pindar has descended to us with honour; but the poems which inspired in his compatriots the most exalted enthusiasm, are but imperfectly understood by the student, and are almost impracticable to translation. The public recitation of the ode was accompanied both by music and dancing: a circumstance to which its structure was obviously adapted. The two first stanzas, called the strophe and the antistrophe, were of equal length. In the first part the performers approached the altars of their god; in the latter, the dance being inverted, they measured back their steps to their former place, where whilst they sung the epode they stood still. It appears that this form was peculiar to the heroic ode. There were other lyrical compositions of a different cast. Sappho's poems respire only tender, impassioned sentiment; those of Anacreon, whether amatory or convivial, are equally remote from the sublimity of Pindar, and the melting softness of Sappho. The fervid imagination of Pindar is compared by Horace to the impetuosity of a mountain torrent:

Monte decurrens velut amnis, imbres
Quem super notas aluêre ripas,
Fervet, immensusque ruit profundo
Pindarus ore:

Pindar, like some fierce torrent swoln with showers,
Or sudden cataracts of melting snow,
Which from the Alps its headlong deluge pours,
And foams and thunders o'er the vales below,
With desultory fury borne along,
Rolls his impetuous, vast, unfathomable song.

West.

The heroic ode is evidently of a dramatic character, and was the primitive source from whence the regular drama was produced. Tragedy originated in the hymns sung in honour of Bacchus; and its name was derived from the goat, which was the victim consecrated to that deity. The invention of dialogue and action belongs to Eschylus; the original ode was preserved in the chorus, which constituted the popular part of the entertainment. The chorus, like the band of a modern orchestra, was composed of several persons who recited in a different manner from the other performers. We learn from Horace that their business was to deduce from the passing scene some lesson of morality, or to inculcate on the spectator some religious precept. The intervention of the chorus, which is now rejected by the most zealous votaries of Greece, is not more repugnant to our ideas of propriety than many other usages of the antient stage: the performers appeared in masks; in their recitations they were constantly accompanied by musical instruments, by which the voice was sustained, and the melody of the verse rendered sensible to an immense audience. The rules of the antient drama were suited to its institution. The unities of time and place were necessary in a performance to which the auxiliary resources of modern machinery were wanting, and from which all the magical illusions of the modern scene were precluded. The tragedies of Euripides and Sophocles were masterpieces in their kind, but would now probably be little relished even by scholars and scholastic enthusiasts.

Comedy, like tragedy, originally consisted of a chorus, which derived its name from the god Comus. The rudiments of the comic art may, perhaps, be detected in the satyrs, a sort of interlude annexed to tragedies, in which the scene was rural, and the personages Satyrs, or sylvan deities. In the plays of Aristophanes, living characters were introduced, and Socrates beheld himself ridiculed on the stage. This abuse a better taste corrected; and the comedies of Menander, which were imitated by Terence, exhibited only interesting pictures of domestic life. The chorus at first appendant on comedy, was gradually changed into the prologue, a personage who carefully apprized the spectators of all they were to see on the stage.

The Roman writers were modelled on those of Greece, and it was long before they attempted to emulate their masters; yet Ennius, one of their elder poets, produced the satire, a species of miscellaneous poetry purely Roman, which was destined to receive perfection from Horace. With equal originality, Lucretius wrote his metaphysical poem, in which are developed the philosophical systems of his age; but it was not till the era of Augustus that the bards of Latium established their equality with those of Greece. It was then that Horace, not satisfied with having transplanted all the lyric beauties to his odes, opened a rich vein of satiric poetry; and Virgil, having equalled Theocritus, without temerity aspired to emulate Homer. In the Æneid it may be acknowledged that he sometimes fell short of his master. His characters possess not the same features of durability and grandeur; nor are his scenes equally animated and dramatic. To atone for these defects, he unites every charm that gives interest to narrative or lends enchantment to description; occasionally he rises to the sublime, but the beautiful is his natural element; he can excite terror, but he is more prone to inspire tenderness and pity. In the delicate touches of nature and pathos, he seems to have grown enamoured of his subject, and to have lingered affectionately on the endearing scenes and charities of domestic life. The four first books of the Æneid contain a tale so sweetly told, that was it transferred to a rude language totally unsusceptible of its literary graces, it would still be read and remembered by all who had capacities for sympathy and tenderness.

In the Georgics, Virgil has left a model of didactic composition, ennobled by a strain of philosophical sentiment, pure, graceful, and persuasive. Ovid, whose talents were not less versatile than those of his contemporaries, adorned the fables of mythology with description, and illustrated in his epistles almost every romantic story of antiquity. The style of his elegies is not unlike that of his epistles: he paints to the eye, but he has often too much wit and fancy to touch the heart.

Tibullus has exceeded every other elegiac writer in simplicity and tenderness. Lucan and Statius were also epic poets, but they are seldom quoted, and not often read. Lucan possessed a genius of an exalted order; but his subject was peculiarly unfortunate, and his beauties are now neglected because they are found in scenes repulsive to the imagination, and uncongenial with the feelings.

Among the last poets of Rome appeared Juvenal and Persius, of whom the former was one of the most original writers she had produced. He professes to exhibit a picture of his times; and there is in his manner an undissembled and almost a holy fervour that atones for his occasional ruggedness and asperity.

Origin of modern poetry.

The Gothic nations who over-ran Rome, though ignorant of the polite arts, were not insensible to the charms of poetry. Their bards were no less venerated than their priests; and whatever instruction they received, whatever knowledge they possessed, was communicated in metre, and probably in rhyme.

In the age of Charlemagne, the minstrels of Provence, or, as they were called, the troubadours, introduced the metrical tales or ballads, which, from the dialect in which they were written, acquired the name of romances. Their poems were all composed in rhyme; but whether this practice was borrowed from the Arabs or the Goths, is uncertain. The Italian language, which of all the corrupt dialects introduced by the barbarians, assimilated most with the Roman, soon acquired a tincture of elegance. In the middle ages Dante wrote; Ariosto followed; and Petrarch, the enthusiastical votary of classical genius, appeared among the first founders of modern literature. The passion for allegory, so long the characteristic of the Italian school, was by Chaucer rendered as prevalent in England as it had previously been on the continent. During several ages, Italy continued to be the Poets' Land of Europe; and in that interval was produced the Jerusalem Delivered, a poem not unworthy of a Roman bard, or an Augustan age.

In Spain, poetry was early cultivated, but with little attention to classical taste. In France, it emerged not from barbarism till the reign of Francis the First, and arrived at its ultimate point of perfection in the era of Louis the Fourteenth. La Fontaine and Boileau, Corneille and Racine, had then lived, and produced works destined to immortalize their names. Unfortunately for French poets, criticism was then almost coeval with poetry; and a pedantic attention to rules was soon permitted to repress the native energies of genius. The modern drama, it is well known, originated in the mysteries; a sort of religious farce, imported from the East. To the mysteries succeeded allegorical plays, called moralities: these produced the mask, which became the favourite amusement of the court in the time of Charles the First, and is redeemed from opprobrium and oblivion by Milton's Comus. Gondibert, written by lord Sackville, was the first tragedy represented on an English stage. Till the commencement of the eighteenth century, the German language was almost a stranger to poetry. Klopstock invented hexameter verse, in which the mechanism of classical numbers is rather perceived than felt by the reader. From that era, Germany has been more productive of books than all the rest of Europe; and during this period, many fine writers have arisen of real and original genius: but the literary commerce of the country is chiefly supported by translation; the Germans having arrived at no less distinction as the general translators, than did their neighbours the Dutch as the carriers, of Europe.

Of English versification.

In the English language, versification depends not on the quantities, or the length and shortness, of the syllables: but on the modulation of the accents, and the disposition of the pauses; to which is generally added the recurrence of rhyme. The heroic verse consists of ten syllables; its harmony is produced by a certain proportionate distribution of accented and unaccented syllables; and its specific character, whether lively or solemn, soft or slow, is determined by their order and arrangement. When unaccented and accented syllables are regularly alternated, it is called the iambic verse; as,

"A shepherd's boy, he seeks no higher name,
Led forth his flock beside the silver Thame."

When this order is inverted, and the unaccented is preceded by the accented syllable, it is called a trochaic verse; as,

"Ambition first *sprung* from the blest abodes."

"*Take*, holy earth, *all* that my soul holds dear."

The frequent intervention of the trochaic is apt to produce harshness. The monotony which it might be expected should result from a succession of iambic lines, is obviated by the freedom with which the pause is transferred from one syllable to another; a freedom which constitutes the charm, and produces all the variety, of English verse. The pause or cesura is that interval of suspension which must naturally arise in every verse, the position of which the English poet is allowed to change and diversify at pleasure. When the pause falls on the fourth syllable, the strain is smooth and airy; as,

"Soft is the strain | when Zephyr gently blows,
And the smooth stream | in smoother numbers flows."

When it falls on the second it is commonly accelerated; as,

"Not so | when swift Camilla scours the plain."

Occasionally the pause dwells on the first, second, or penultimate syllable:

"O friend! | may each domestic bliss be thine:
Be no unpleasing melancholy | mine.
Me,| let the tender office long engage,
To rock the cradle of declining age."

A second pause is sometimes happily introduced:

"O ever beauteous | ever lovely! | tell,
Is it in heaven a crime to love too well?"

In the following examples, the first passage has all the spirit and energy of the ode; the second, the slow and plaintive melody of the elegiac strain:

"Come then, my friend, my genius, come along,
O master of the poet and the song!
And while the muse now stoops, | and now ascends,
To man's low passions, | or their glorious ends,
Teach me, like thee, | in various nature wise,
To fall with dignity, | with temper rise;
Form'd by thy converse, | happily to steer
From grave to gay, | from lively to severe;
Correct with spirit, | eloquent with ease,
Intent to reason, | or polite to please."

"In these deep solitudes, | and awful cells,
Where heavenly pensive contemplation | dwells,
And ever-musing melancholy reigns."

The heroic verse is often diversified by the intervention of an Alexandrine line of twelve syllables, which is liberally used by Dryden: its abuse is pointedly censured by Pope:

"A needless Alexandrine ends the song,
Which, like a wounded snake, drags its slow length along."

It forms a noble termination:

"Teach me to love and to forgive;
Exact my own defects to scan,
What others are to feel, and know myself a man."

Triplets often occur in heroic verse; a practice to which Dryden was strongly addicted, but which is now generally avoided by correct writers.

The stanza of nine lines, in imitation of the Italian, was introduced by Spenser. Of this verse, which, if not impracticable, was at least repugnant, to the English language, the following extract is a favourable specimen:

"A gentle knight was pricking on the plaine,
Yclad in mightie arms, and silver shield,

Wherein old dintes of deep woundes did remain,
The cruel marks of many a bloody field;
Yet armes till that time did he never wield.
His angry steed did chide his foaming bitt,
As much disdaining to the curb to yield:
A jolly knight he seem'd, and faire did sit,
As one for knightly guests and fierce encounters fitt."

A stanza more polished in its structnre is adopted by Mr. Sotheby in his admirable translation of Wieland's Oberon. The folling passage describes Rezia's first interview with the Hermit·

" Rezia, at once entranced in holy bliss,
Aw'd by his look, that beams celestial grace,
Bows, as before the genius of the place,
And prints his wrinkled hand with pious kiss.
Touched by his gracious mien or friendly air,
His beard that swept his breast with silver hair,
Her soul this stranger as her sire reveres;
A second look has banish'd all her fears:
Each reads the other's heart, nor finds a stranger there."

The most popular stanza is that appropriate to the ballad, which is composed of four lines with interchanging rhymes. Such is the measure of Goldsmith's beautiful tale of Edwin and Angelina:

" Turn, gentle hermit of the dale,
And guide my lonely way,
To where yon taper cheers the vale
With hospitable ray."

And such, with the remission of rhyme in the first and third lines, is the measure of Chevy Chace:

" God save the king, and bless the land,
In plenty, joy, and peace;
And grant henceforth that foul debate
'Twixt noblemen may cease !"

The elegiac stanza consists of four alternately responsive lines of ten syllables each: it is well adapted to short poems; but in composition of any length, its slow monotonous cadence becomes oppressive to the ear. In the celebrated elegy of Gray, its defects, however, are all concealed by a profusion of poetical beauties; and by the graceful muse of Hammond its fetters are rendered elegant and ornamental:

" Why should the lover quit his pleasing home,
In search of danger on some foreign ground?
Or from his weeping fair ungrateful roam,
And risk in every stroke a double wound?
Ah! better far, beneath the spreading shade,
With cheerful friends to drain the sprightly bowl,
To sing the beauties of my darling maid,
And on the sweet idea feast my soul."

The common anapestic verse, of eleven and twelve syllables, in which the accent falls on every third syllable, has generally been appropriated to humorous subjects: when formed into the stanza, it assumes a different character. In the noble war-song of Burns it is however a strain truly sublime; and in the following passage flows with equal sweetness and pathos:

" 'Tis night, and the landscape is lovely no more:
I mourn, but, ye woodlands, I mourn not for you;
For morn is approaching, your charms to restore,
Perfum'd with fresh fragrance, and glittering with dew.
Nor yet for the ravage of winter I mourn;
Kind nature the embryo blossom will save:
But when shall spring visit the mouldering urn?
Oh! when shall it dawn on the night of the grave?"

This stanza is, from the intractable nature of the anapestic measure, of difficult execution. In that employed by Cowper in the following instance, constructed on similar principles, the syllables are less numerous, and the cadence is in general more harmonious:

" I am monarch of all I survey,
My right there is none to dispute;
From the centre, all round to the sea,
I am lord of the fowl and the brute.
O Solitude ! where are the charms
That sages have seen in thy face?
Better dwell in the midst of alarms
Than reign in this desolate place."

The occurrence of double rhymes is neither very frequent nor very easy in English verse; they are chiefly employed in songs, and are seldom admitted in the higher order of lyrical composition. The following passage from Dryden's ode on St. Cecilia's day, affords the most happy example of this kind of verse in our language :

" Softly sweet in Lydian measures,
Soon he sooth'd his soul to pleasures;
War, he sung, is toil and trouble,
Honour but an empty bubble;
Never ending, still beginning,
Fighting still, and still destroying:
If the world be worth thy winning,
Think, oh ! think it worth enjoying."

The simplest and most fluent of all verse is the couplet of eight syllables. In this measure Milton has written his two exquisite poems, the Allegro and Penseroso :

" And may at length my weary age
Find out the peaceful hermitage,
The hairy gown and mossy cell,
Where I may sit, and rightly spell
Of every star that heaven doth shew,
And every herb that sips the dew,
Till old experience do attain
To something like prophetic strain!"

Pope and Gray are generally considered as the most correct writers of rhyme; and Dryden, who knew the affluence of the English language, has in his own compositions exhibited all its various capacities of harmony and versification.

Blank verse

Is composed of lines of ten syllables each, which flow into each other without the intervention of rhymes; its metrical principle resides in its pauses, which should be so judiciously spread as never to suffer the accompaniment of rhyme to be missed. Of the few poets who have attempted this species of composition, Milton first, and after him, Thomson, Armstrong, Akenside, and Cowper, are pre-eminent. The amplitude of Milton's verse is unequalled: it dilates with the author's thought, it harmonizes with the reader's sentiment, and its varied cadence alternately rolls with majesty, or falls in a mellifluent strain of melody on the unwearied and unsated ear. The principle of this exquisite mechanism has been lately referred by a judicious critic (the Rev. Mr. Crowe, in his Lectures at the Royal Institution), to Milton's bold practice of distributing in separate lines, words so nearly connected (such as the preposition governing the noun, and the pronoun attached to the verb) as almost to appear indivisible. That this practice, which Mr. Crowe calls *breaking the natural joint of the sentence*, is favourable to the freedom of blank verse, cannot be disputed; but it may be questioned whether the poet was himself conscious of the mechanism which he employed, or was directed by any other principle than his own acute sensibility to harmony. The following short extracts may illustrate the difference of style perceptible in the various writers of blank verse :

" Of man's first disobedience, and the fruit
Of that forbidden tree whose mortal taste
Brought death into the world, and all our woe,
With loss of Eden, till one greater man
Restore us, and regain the blissful seat,
Sing, heavenly muse that on the secret top
Of Oreb, or of Sinai, didst inspire
The shepherd who first taught the chosen seed,
In the beginning how the heavens and earth
Rose out of chaos; or if Sion hill
Delight thee more, and Siloa's brook that flowed
Fast by the oracle of God, I thence
Invoke thy aid to my adventurous song;
That with no middle flight intends to soar
Above the Aonian mount, while it pursues
Things unattempted yet in prose or rhyme."
MILTON.

" He comes! he comes! in every breeze, the power
Of philosophic melancholy comes:
His near approach the sudden-starting tear,
The glowing cheek, the mild dejected air,
The soften'd feature, and the beating heart
Pierc'd deep with many a virtuous pang, declare.
O'er all the soul his sacred influence breathes,
Inflames imagination, through the breast
Infuses every tenderness, and far
Beyond dim earth exalts the swelling thought."
THOMSON.

" From heaven my strains begin; from heaven descends
The flame of genius to the chosen heart,
And beauty with poetic wonder join'd
And inspiration. Ere the rising sun
Shone o'er the deep, or mid the vault of night
The moon her silver lamp suspended ; ere
The vales with spring were watered, or with groves
Of oak, or pine, the antient hills were crown'd;
Then the great Spirit whom his works adore,
Within his own deep essence view'd the forms,
The forms eternal of created things :
The radiant sun, the moon's nocturnal lamp,
The mountains and the streams, the ample stores
Of earth, of heaven, of nature. From the first,
On that full scene his love divine he fix'd,
His admiration ; till in time complete,
What he admired and lov'd, his vital power
Unfolded into being."
AKENSIDE.

"O ye whose souls relentless love has tam'd
To soft distress, or friend untimely fallen!
Court not the luxury of tender thought;
Nor deem it impious to forget those pains
That hurt the living, nought avail the dead.
Go, soft enthusiast, quit the cypress groves;
Nor to the rivulet's lonely moanings tune
Your sad complaint. Go, seek the cheerful haunts
Of men, and mingle with the bustling crowd;
Lay schemes for wealth, or power, or fame—the wish
Of nobler minds, and push them night and day;
Or join the caravan, in quest of scenes
New to your eyes, and shifting every hour,
Beyond the Alps, beyond the Appenines."

ARMSTRONG.

"O winter, ruler of the inverted year,
Thy scattered hair, with sleet like ashes fill'd,
Thy breath congeal'd upon thy lips, thy cheeks
Fring'd with a beard made white with other snows
Than those of age, thy forehead wrapt in clouds,
A leafless branch thy sceptre, and thy throne
A sliding car indebted to no wheels,
But urg'd by storms along its slippery way!
I love thee, all unlovely as thou seem'st,
And dreaded as thou art. Thou hold'st the sun
A pris'ner in the yet undawning east,
Short'ning his journey between morn and noon,
And hurrying him, impatient of his stay,
Down to the rosy west; but kindly still
Compensating his loss with added hours
Of social converse, and instructive ease."

COWPER.

The defect of Young's blank verse is, that the sense commonly closes with the line, and that it has too much of the systematical uniformity, without the musical varieties, of rhyme. Whether rhyme or blank verse is entitled to pre-eminence, is a question which must ultimately be determined by individual taste. In the choice of his measure, the poet must obviously be influenced by the nature of his subject; and rhyme or blank verse will alternately obtain his preference. In all the gay and airy excursions of fancy, or the lighter touches of feeling, he will find in rhyme an auxiliary equally pleasing and important. To such compositions as require a measure of spirited and vivacious movement, rhyme is an indispensable appendage. To satire it adds poignancy, to humour it gives elegance; it imparts renovation to old ideas, and lends attraction to trivial sentiments; it renders familiar illustration graceful, and plain sense eloquent. In all but the Alpine regions of poetry, rhyme is a fence no less useful than ornamental, enriching and enlivening every object. In the Allegro and Penseroso, even Milton conceived it no dereliction of poetical freedom to have pursued the path traced out by his predecessors: but in his Paradise Lost, when "he soared beyond the visible diurnal sphere," his deviation into blank verse was as judicious as fortunate; because his subject was then too sublime, his conceptions too gigantic, for the narrow limits and demarcations of rhyme. Wherever much originality of thought exists, this metrical charm is unnecessary; and where imagination reigns in wild luxuriance, it is impertinent. In some of his juvenile poems, Milton appears to have been incumbered with the dignity of his thoughts; and Shakspeare, perplexed by the richness and variety of his combinations, is apt to become affected when he quits blank verse. Attempts have been made to enlarge the limits of blank verse, by the introduction of various measures analogous to those employed in rhyme: but to all these efforts the genius of the language discovers an invincible repugnance; vainly are varieties presented to the eye, which are imperceptible to the mind, and untasted by the ear. All rhymeless numbers either flow into good blank verse, or form lines harsh and intractable; a succession of abrupt sounds and mutilated sentences, which by no art of typography, by no imposition of nomenclature, can be made to constitute any metre at all.

Poetical classification.

The primitive sources of modern poetry may be traced to the old romance; whence was derived the simple ballad so popular in England and Scotland, and under various names and forms universally adopted in Europe. On the revival of letters, when the study and imitation of the classics became the passion of all literary men, their nomenclature was eagerly assumed; and volumes of poetry were soon composed, which the high-sounding names of odes, pastorals, satires, and epic poems, have not saved from oblivion; volumes of criticism were also compiled, to shew how pastorals, odes, and satires, ought to have been written.

PASTORAL poetry is, above all other, the most limited in its object; and when formed on the model presented to us by Virgil and Theocritus, should be a description of rural scenes and natural feelings, enriched with elegant language, and adorned by the most melodious numbers.

Few English pastorals will be recognized in this definition; the scenes they represent are artificial, and the sentiments factitious, because they are imitated from other poets, the natives of a luxuriant region, accustomed to the living tints and glowing azure of a cloudless sky. From this censure, however, the pastoral drama of Allan Ramsay must be excepted, as should Shenstone's celebrated ballad. The ballad is perhaps the happiest vehicle of pastoral poetry, and there are in our language many ballads of exquisite beauty. Some of our pastorals are elegiac; such is Milton's monody on Lycidas:

"Together both, ere the high lawns appear'd
Under the opening eyelid of the Morn,
We drove afield; and both together heard
What time the grey fly winds her sultry horn,
Batt'ning our flocks with the fresh dews of night,
Oft till the star that rose at evening bright,
Towards heaven's descent had slop'd his westering wheel."

The conclusion of this poem is in the true spirit of elegant pastoral:

"Thus sung the uncouth swain to th' oaks and rills,
When the still Morn went out in sandals grey;
He touch'd the tender stops of various quills,
With eager thought, warbling his Doric lay:
And now the sun had stretch'd out all the hills,
And now was dropt into the western bay.
At last he rose, and twitched his mantle blue,
To-morrow to fresh woods, and pastures new."

The name of ELEGY was originally given to funereal monody, but was afterwards attached to all plaintive strains. In the Latin language it was always written in hexameter and pentameter verse. By the moderns an elegiac stanza was invented, assimilating as nearly as possible with those slow melodious numbers. Many elegies, and perhaps the best, are expressive only of soothing tenderness. Such are those of Tibullus, so happily imitated by Hammond. The Jesse of Shenstone, which has perhaps never been surpassed, is all pathos. The celebrated elegy of Gray combines every charm of description and sentiment. The elegiac stanza, the monotony of which soon becomes oppressive to the ear, is sometimes happily exchanged for a lighter measure, as in Cowper's Juan Fernandez:

"Ye winds that have made me your sport,
Convey to this desolate shore
Some cordial endearing report
Of a land I shall visit no more.
My friends do they now and then send
A wish or a thought after me?
Oh! tell me I yet have a friend,
Though a friend I am never to see."

The SONNET represents in an abridged form the antient elegy; the same slow stanza is assigned to each, and the sentiments suitable to the one are appropriate to the other. The sonnet is derived from the Italian school, and was much cultivated in England during the seventeenth century. It is always limited to fourteen lines, an artificial character which should seem to indicate an Oriental extraction. The following, by Milton, is a fine specimen of the English sonnet in the Italian manner:

"O nightingale, that on yon leafy spray
Wast blest at eve, when all the woods are still!
Thou with fresh hopes the lover's heart dost fill,
When the jolly Hours lead on propitious May.
Thy liquid notes, that close the eye of Day,
First heard before the shallow cuckoo's bill,
Portend success in love. Oh! if Jove's will
Have link'd that amorous power to thy soft lay,
Now timely sing, ere the rude bird of hate
Foretell my hopeless doom in some grove nigh,
As thou from year to year hast sung too late
For my relief, yet hadst no reason why.
Whether the muse or Love call thee his mate,
Both them I serve, and of their train am I."

In the following sonnet, which is of a modern date, the stanza is happily accommodated to the English language:

Written in the church-yard of Middleton, Sussex.

"Press'd by the moon, mute arbitress of tides,
Whilst the loud equinox its power combines,
The sea no more its swelling surge confines,
But o'er the shrinking land sublimely rides.

The wild blast rising from the western cave,
Drives the huge billows from their heaving bed,
Tears from their grassy tombs the village dead,
And breaks the silent sabbath of the grave.
With shells and sea-weed mingled on the shore,
Lo! their bones whiten on the frequent wave.
But vain to them the winds and waters rave,
They hear the warring elements no more;
While I am doom'd, by life's long storm opprest,
To gaze with envy on their gloomy rest."

Pope's Elegy to an Unfortunate Lady, and his Eloisa, are in heroic verse; which, in the hands of that great master, is adequate to the expression of every feeling.

Lyric poetry is versatile and miscellaneous, admitting almost every diversity of measure and of subject. Love and heroism, friendship and devotional sentiment, the triumphs of beauty and the praises of patriotism, are all appropriate to lyrical composition. The soul of enthusiasm, the spirit of philosophy, the voice of sympathy, may all breathe in the same ode. Of our lyrical writers, Dryden is confessedly eminent; Gray is distinguished by the majesty and delicacy of his expression, and the correctness of his style; Collins is occasionally animated by a portion of Pindaric spirit. Among our heroic odes there are, perhaps, none that breathe a loftier strain than the following patriotic invocation by Burns:

"Scots, who have with Wallace bled,
Scots, whom Bruce hath often led,
Welcome to the gory bed,
Or to glorious victory.

Now's the day, and now's the hour,
See the front of battle lower;
See approach proud Edward's power,
Edward's chains and slavery.

Who will be a traitor knave?
Who can ask a coward's grave?
Who so base to be a slave?
Traitor, coward, turn and flee.

Who for Scotland, king, and law,
Freedom's sword will strongly draw,
Freeman stand, and freeman fa'?
Caledonian, on wi' me.

By oppressions, woes, and pains,
By your master's servile chains,
We will draw our dearest veins,
But they shall be, shall be free.

Lay the proud usurpers low;
Tyrants fall in every foe,
Liberty's in every blow:
Forward let us do, or die."

In the minor lyrics are included Songs, a species of composition sedulously cultivated by English writers. The themes of songs are in general amatory or convivial; there are however some, of which the strain is purely patriotic and martial; and not a few are of the humorous cast. Shakspeare, Jonson, and our other elder bards, have bequeathed to us songs of exquisite beauty. In the last century the most popular song-writer was Gay. Allan Ramsay has left some enchanting airs. Percy's collection has restored many lyrical pieces of inimitable pathos and simplicity. In latter times, many songs of classical eminence have been supplied by Stevens, Sheridan, and Burns.

Didactic poetry is minutely preceptive, and professes to convey useful instruction on some particular subject. It is obviously not easy to discover situations in which an author may become a practical teacher, without ceasing to be the poet: and this difficulty is aggravated to the English writer, who has not the resources of the Greek and Roman in the metrical capacities of his language.

Virgil's georgical poem is the performance of the first master, operating with the best materials. In imitation of Virgil, a poem was composed by John Phillips on cyder, which is now little read. Towards the middle of the last century, when the didactic muse had most votaries, polemics, physics, and metaphysics, were successively expounded in verse. But verse is not the medium by which information can be communicated with most advantage; and is less suitably employed in elucidating abstract speculation, than in enforcing popular and acknowledged truths. The philosophy of Akenside is relished only for his imagery and harmonious language. The aphorisms of Armstrong are remembered only where the author was more sensible to the influences of Apollo than of Esculapius. The Economy of Vegetation, and the Loves of the Plants, are formed on a plan not only original, but new. It is probable that the primary idea of this work was suggested to the author by the perusal of Cowley's Garden; but on that simple site he has erected a magnificent palace, in which no vestige of the antient edifice remains. With an imagination luxuriant as that of Ovid, and with powers of description scarcely less universal, he has invented a machinery appropriate to his subject, and which is also derived solely from the philosophy of modern times. From the extensive notes appended to his poems, it is however obvious, that though he might thus embody the principles of science to the eye of fancy, he despaired of rendering them intelligible without the agency of prose. Mason's English Garden is more descriptive than didactic. De Lille's Jardins is a chef-d'œuvre in its kind. In the Essay on Criticism, Pope has most happily enlivened didactic style with wit and satire.

Satirical poetry is descriptive of men and manners; its aim is to delineate the follies and chastise the vices of the age. Satire is evidently the offspring of polished times; and, unlike other poets, the satirist finds his empire enlarged, and his influence extended, by the progress of society.

Satire is either pointed or oblique: eloquence is the soul of the one, ridicule of the other. The one rushes on its object in a torrent of vehemence and declamation; the other pursues a smooth tortuous course, occasionally reflecting to the mind the most momentous truths in the playful aspect of wit and humour. In the Hudibras of Butler, the Lutrin of Boileau, and the Rape of the Lock, the effect of oblique satire is heightened by an assumption of the heroic style, the perversion of which produces an effect exquisitely ludicrous. Gay's Shepherd's Week and Gresset's Ver-vert belong to this species, as do many of Voltaire's lighter poems, and many of La Fontaine's tales. Swift's satire is commonly of a similar cast. The satire of Young is always pointed and saturnine. In Churchill the pointed and the oblique are happily united: as they are in Dryden and Pope, the two great original masters of English satire, who both possessed with wit and fancy a knowledge of men and manners, and an intuitive discernment of characters, with the aptitude of describing them, which are its first requisites. The following extracts afford a specimen of the manner of each in the delineation of character: it must, however, be remembered, that Pope moralizes whilst Dryden declaims:

"Some of their chiefs were leaders of the land:
In the first rank of these did Zimri stand;
A man so various, that he seem'd to be
Not one, but all mankind's epitome.
Stiff in opinion, always in the wrong,
Was every thing by starts, and nothing long;
But in the course of one revolving moon,
Was chemist, fidler, statesman, and buffoon;
Then all for women, painting, rhyming, drinking,
Beside ten thousand freaks that died in thinking.
Blest madman! who could every hour employ
With something new to wish, or to enjoy.
Railing and praising were his usual themes;
And both to shew his judgment in extremes.
Is ever violent, or ever civil,
That every man with him was God or devil.
In squandering wealth was his peculiar art;
Nothing went unrewarded but desert:
Beggar'd by fools, whom still he found too late,
He had his jest, and they had his estate.
He laugh'd himself from court; then sought relief
In forming parties, but would ne'er be chief."

Dryden.

"In the worst inn's worst room, with mat half-hung,
The walls of plaister, and the floor of dung;
On once a flock-bed, now repair'd with straw,
With tape-tied curtains never meant to draw;
The George and garter dangling from his head,
Where tawdry yellow strove with dirty red;
Great Villiers lies: alas! how chang'd from him
The life of pleasure, and the soul of whim,
Gallant and gay, in Cliveden's proud alcove,
The bower of wanton Shrewsbury, and love;
Or just as gay at council, in a ring
Of mimic statesmen and their merry king.
No wit to flatter left of all his store;
No fool to laugh at, which he valued more,
The victor of his health, his fortune, friends,
And fame, this lord of useless thousands ends."

It would be amusing to pursue the comparison between those two great poets in the Dunciad and Mac Flecnoe; to observe the unpruned exuberance and careless vigour of the elder bard, and the exquisite judgment of his incomparable imitator.

Epic poetry concentrates all that is sublime in action, description, or sentiment. In the structure of a regular epic poem, criticism requires that the fable should be founded in fact, and that fiction should fill the picture of which the outline is traced by truth. In the conduct of the poem, it is exacted that the machinery be subservient to the main design, and that the action should be simple and uniform. In the Iliad, the action is limited to the destruction of Troy, which is only to be effected by the conciliation of Achilles to the common cause. In the Odyssey, it is the establishment of Ulysses in Ithaca; an event which, after innumerable difficulties, he is finally enabled to accomplish. In the Æneid the hero is destined to found a Trojan colony in Latium. In the Jerusalem Delivered, the object of the poem from its commencement to its close, is the restoration of that city to the Christians. Criticism requires also that poetical justice should be dispensed to all parties, success being awarded to the virtuous, and punishment inflicted on the guilty. On these principles, three authors only, Homer, Virgil, and Tasso, have produced epic works. There are however many poems of the epic or heroic cast to which criticism has hitherto assigned no name. Such are the Lusiad of Camoens, and the Henriade of Voltaire; and in the Paradise Lost, Milton appears in solitary majesty and magnificence. He maintains a lofty independance of rules and systems, and eternizes to himself a distinction superior to all that criticism has to withhold or to bestow. The Inferno of Dante, the Orlando of Ariosto, the Fairy Queen of Spenser, are romances; a species of composition purely fictitious, in which no other restriction is imposed on the poet's fancy than that he shall continue to interest and amuse his reader. Several romances of a recent date are intitled to praise: such as the Oberon of Wieland, ably translated by Mr. Sotheby; the Thalaba of Southey, of which the beauties would be more generally appreciated if the work was less tinged with gloom; and the Lay of the Last Minstrel, in which a fable of the most superficial texture is drawn out in a succession of scenes which perpetually animate and delight the imagination. It is obvious, that the poetical nomenclature established on classical authority, is not sufficiently extensive to include all the compositions of modern times. To what classical school shall we refer the noble ethics of Pope in his Epistles, and of Cowper in his Task? By what name shall we designate the Traveller and the Deserted Village, the Pleasures of Memory, the Pleasures of Hope, (neither of which is, like the Pleasures of Imagination, included in the didactic species), with many other exquisite productions? Ossian's poems have been classed with epic compositions, but are more analogous to the old heroic lays chanted by the scalds, bards, and minstrels. The relics of Scandinavian literature afford many specimens of poetry which, though inferior in beauty, are obviously of similar origin and execution.

Originally the DRAMA was a metrical composition, and exhibited all the critical refinements of poetry. The title of poet is still given to every dramatic author, although he should have written in prose, and although the highest dramatic powers may exist without the smallest talent for poetry. The avowed object of the drama is to develope the passions, or to delineate the manners of mankind: tragedy effects the one, and comedy the other. In the English language are many popular dramas of a mixed character, which are written in verse, intermingled with prose, and which are called *plays*. The best pieces in Beaumont and Fletcher, and even Shakspeare, belong to this order. The English drama deviates essentially from that of classical antiquity; and independant of the division of acts and scenes, there is little resemblance between them. The triple unities of time, place, and action, are seldom observed on the English stage; and our best writers have allowed, that between the acts any change of scene is admissible. In reality this operation is performed in most tragedies and all comedies, at any season, without either condition or restriction; nor is, perhaps, any change censurable, the cause and object of which is immediately comprehended by the audience. To the limitation of time more attention is paid. In many tragedies the action is included in one day. Unity of design is obviously an obligation imposed by good sense; and Shakspeare, guided only by his feelings of propriety, is in general careful to exclude from his plays a divided interest, an error perpetually committed by Beaumont and Fletcher, and his other dramatic contemporaries. To construct a truly dramatic fable is no easy task. The author has to provide sources of constantly augmenting interest, to present characters, to suggest situations capable of extorting from the spectators an active participation in the scene; above all, to supply a series of natural incidents, the springs of dramatic action, by which all the life and motion of the piece are produced. The dramatic style should imbibe its character from that of the individuals presented in the scene, and transmit the impression of every feeling which is there pourtrayed. On this excellence is founded the superiority of Shakspeare to all other dramatists; from him each passion receives its appropriate language. With a few masterly touches, he lays open the heart, exhibits its most secret movements, and excites in every bosom correspondent emotions. The poet who, next to Shakspeare, has excelled in the dramatic style, is Otway. The tragedies of Rowe possess extraordinary merit. In the plays of Beaumont and Fletcher, and Massinger, are innumerable passages of high poetical beauty; and in those of Dryden are discovered the most brilliant combinations of thought and fancy: but the touches of nature are still wanting; that true dramatic idiom which is instantly understood by the heart, and the absence of which is not compensated by beautiful imagery, or the most refined graces of composition. Dramatic blank verse, when flowing with freedom and facility, is more happily adapted than prose to the expression of strong emotion; it is not only more harmonious, but more concise; and being exonerated from that metrical precision which is expected in other poetry, is simply the language of impassioned feeling. Much of the imagery which might delight in the closet, would offend on the stage: yet figurative language is often employed with great effect in describing the tempestuous passions. In a state of agitation the mind becomes peculiarly susceptible of new combinations. Grief is eloquent: and though the chain of thought is too tenacious to be broken by sensible impressions, it discovers in every external object some typical illustration of its own sufferings; some image which, by a kind of fictitious sympathy, seems respondent to its individual feelings. Thus Lear, though insensible to the storm, invokes the elements, reverting to the contumely he has experienced:

"I tax not you, ye elements, with unkindness;
I never gave you kingdom, call'd you children;
You owe me no subscription."

In impassioned language, even a mixture of metaphors is not indefensible; in a moment of distraction the mind is versatile, and indistinct in its perceptions; and consequently becomes liable to form abrupt, desultory, and even incongruous associations.

Of metrical harmony and poetical emotion.

Metrical harmony is but the medium by which the poet transmits his ideas and sentiments: it constitutes the fabric into which his conceptions are wrought, the form in which his sentiments are exhibited. Metrical harmony is common to all who assume the name of poets; from the humble versifier creeping through hedge-rows of rhyme at the foot of Parnassus, to the son of genius, who has drunk of inspiration at its source, and rides

"Upon the seraph wing of ecstacy."

It has appeared difficult to suggest a proper mode of distinction between these two orders of writers; and it has been often asked, what the real difference is between the legitimate bard and a maker of pretty verses: their respective pretensions might, it should seem, be amicably adjusted, by leaving to the former an exclusive right to the character of poet, and assigning the rank of metrical poets to the latter. There is in metrical harmony a charm that often renders a trivial thought pleasing. There are also certain agreeable epithets which, if not egregiously misplaced, must always call to the mind grateful associations; and which when aided by melodious verse, will generally impart some transient sensation of pleasure. To awaken strong and permanent feelings of delight, is the prerogative only of the original bard. Poetical emotion springs from admiration or from sympathy, and may be awakened by the novelty or the renovation of sensation. It may arise from combinations new to the fancy, or from recollections interesting to the heart. In the energy of his conceptions, and in the charm of his expression, resides all the poet's power. There are no features of sublimity and magnificence, no touches of tenderness or pathos, but may be traced to those two sources of poetical excellence. Sublimity originates in the amplitude of the poet's mind, and is discovered in the majesty of his images, or the grandeur of his sentiment: a sensation of terror, mingled with admiration, also belongs to the sublime. Such is the sensation awakened by Milton's awful description of the infernal portals:

"On a sudden open fly
With impetuous recoil, and jarring sound,
Th' infernal doors, and on their hinges grate
Harsh thunder, that the lowest bottom shook
Of Erebus."

What follows is in the true spirit of terrific sublimity:

"She opened; but to shut
Excell'd her power. The gates wide open stood;
That with extended wing a bannered host,

Under spread ensigns marching, might pass through
With horse and chariots rank'd in loose array.
So wide they stood; and like a furnace-mouth
Cast forth redounding smoke, and ruddy flame.
Before their eyes in sudden view appear
The secrets of the hoary deep; a dark
Illimitable ocean, without bound,
Without dimension, where length, breadth, and highth,
And time, and place, are lost."

Sublimity is produced by grandeur of sentiment:

"Farewell, happy fields,
Where joy for ever dwells. Hail, horrors! hail,
Infernal world! and thou, profoundest hell,
Receive thy new possessor, one who brings
A mind not to be chang'd by place or time.
The mind is its own place; and in itself
Can make a heaven of hell, a hell of heaven."

In sublime composition no image should be introduced which is not calculated to impress the mind with feelings of solemnity. The following description of Satan exemplifies the union of sublime imagery, with sublimity of sentiment. There is even something like pathos in the concluding passage:

"He, above the rest
In shape and gesture proudly eminent,
Stood like a tower. His form had not yet lost
All her original brightness; nor appear'd
Less than arch-angel ruined, and the excess
Of glory obscur'd; as when the sun, new-risen,
Looks through the horizontal misty air,
Shorn of his beams; or from behind the moon,
In dim eclipse, disastrous twilight sheds
On half the nations, and with fear of change
Perplexes monarchs. Darkened, so yet shone
Above them all the arch-angel; but his face
Deep scars of thunder had entrench'd, and care
Sat on his faded cheek; but under brows
Of dauntless courage, and considerate pride
Waiting revenge; cruel his eye, but cast
Signs of remorse and passion, to behold
The fellows of his crime (the followers rather)
Far other once beheld in bliss, condemn'd
For ever now to have their lot in pain.
Millions of spirits, for his fault, amerc'd
Of heaven, and from eternal splendour flung,
For his revolt; yet faithful how they stood;
Their glory withered, as when heaven's fire
Hath scathed the forest oak, or mountain pine,
With singed top their stately growth, though bare,
Stands on the blasted heath. He now prepared
To speak, whereat their double ranks they bend
From wing to wing, and half-inclose him round
With all his peers: attention held them mute.
Thrice he assay'd; and thrice, in spite of scorn,
Tears, such as angels weep, burst forth: at last
Words, interwove with sighs, found out their way."

An energetic simplicity is essential to the sublime, which disclaims artificial ornament. Description includes many of the elements of poetry, and alternately produces emotions of sublimity and beauty. The figurative style is often assumed, in order to give more richness and vividness to description. The elements are thus embodied, and morn and evening are perpetually represented under some popular and pleasing image. Thus Milton personifies the morning:

"Now Morn, her early steps in the eastern clime
Advancing, sowed the earth with orient pearl."

And Shakspeare:

"But see, the Morn, in russet mantle clad,
Walks o'er the dews of yon high eastern hill."

Description is sometimes rendered more lively by the introduction of a figurative allusion. Thus, in the Allegro, Milton illustrates his description of sun-rise:

"Sometimes walking not unseen,
By hedge-row elms, or hillocks green,
Right against the eastern gate,
Where the great sun begins his state,
Rob'd in flames and amber bright,
The clouds in thousand liveries dight."

In Il Penseroso he again enlivens his imagery by an interesting allusion:

"Missing thee, I walk unseen
On the dry smooth-shaven green,
To behold the wandering moon
Riding near her highest noon,
Like one that had been led astray
Through the heaven's wide pathless way;
And oft as if her head she bow'd,
Stooping through a fleecy cloud."

In Dryden's poem of the Flower and the Leaf is the following beautiful illustration of the spring:

"When first the tender blades of grass appear,
And buds, that yet the breath of Eurus fear,
Stand at the door of life, and ask to clothe the year."

Poetical description is either general or local, and admits of artificial or simple imagery. In the two following passages Pope exemplifies the difference of general and local description:

"Thy trees, fair Windsor, now shall leave their wood,
And half thy forests rush into my flood;
Bear Britain's thunder, and her cross display,
To the bright regions of the rising day;
Tempt icy seas, where scarce the waters roll,
Where clearer flames glow round the frozen pole;
Or under southern skies exalt their sails,
Led by new stars, and borne by spicy gales.
For me the balm shall bleed, the amber flow,
The coral redden, and the ruby glow,
The pearly shell its lucid globe enfold,
And Phœbus warm the rip'ning ore to gold."

Here the author dwells not sufficiently long on any object to leave a distinct picture on the mind. But in the ensuing lines the delineation is too bold to be missed:

"In genial spring, beneath the quiv'ring shade,
Where cooling vapours breathe along the mead,
The patient fisher takes his silent stand,
Intent, his angle trembling in his hand;
With looks unmov'd he hopes the scaly breed,
And eyes the dancing cork and bending reed.
Our plenteous streams a various race supply;
The bright-ey'd perch, with fins of Tyrian dye;
The silver eel, in shining volumes roll'd;
The yellow carp, in scales bedropt with gold."

The two following extracts from Milton happily illustrate the difference of artificial and simple imagery:

"Now the bright morning-star, day's harbinger,
Comes dancing from the east, and leads with her
The flowery May, who from her green lap throws
The yellow cowslip, and the pale primrose.
Hail, beauteous May, that doth inspire
Mirth, and youth, and warm desire!
Woods and groves are of thy dressing,
Hill and dale doth boast thy blessing."

"While the plowman near at hand,
Whistles o'er the furrow'd land;
And the milkmaid singeth blithe,
And the mower whets his sithe,
And every shepherd tells his tale
Under the hawthorn in the dale."

In general description, it is the poet's object to force on the mind a variety of brilliant ideas and vivid impressions. In his local or individual delineations, he presents images palpable to the imagination, and almost to the senses; he stimulates latent feelings, or renovates forgotten sensations. In the combination of artificial imagery, he employs the power of novelty; in that of simple images, he relies on the charm of truth. With the one the attention is awakened, by the other it is absorbed. The reader perceives in himself a capacity for forming associations till then unknown; but he is yet more pleased to retrace scenes and sentiments familiar to memory, and dear to the heart. In one instance he is astonished by the variety of the poet's conceptions, in the other he is enchanted by the fidelity of his imitations. The magnificence of figurative language and metaphorical description extorts admiration; the simplicity of natural images inspires delight. In local description the poet should introduce only such objects as harmonize perfectly with his design. Thus in his delicious landscape of Eden, Milton carefully avoids the intrusion of exotic imagery:

"Thus was this place
A happy rural seat, of various views:
Groves, whose rich trees wept odorous gums and balms;
Others, whose fruit burnished with golden rind
Hung amiable, Hesperian fables true
(If true), here only, and of delicious taste.
Betwixt them, lawns, or level downs, and flocks
Grazing the tender herb were interposed.
Or palmy hillock, or the flow'ry top
Of some irriguous valley, spreads her store;
Flowers of all hue, and without thorn the rose.

"Another side umbrageous grots and caves
Of cool recess, o'er which the mantling vine
Lays forth her purple grape, and gently creeps
Luxuriant: meanwhile, murmuring waters fall
Down the slope hill dispers'd; or in a lake

That to the fringed bank, with myrtle crown'd,
Her crystal mirror holds, unite their streams."

There is in local description a charm that renders objects, in themselves uncongenial, engaging to the mind. The following passage presents few images of beauty: but in contemplating it, who does not feel, that without being removed from the common walk of nature, he is visited by the influences of poetry?

"The day is come, when I again repose
Here under this dark sycamore, and view
Those plots of cottage ground, the orchard tufts,
Which at this season, with their unripe fruits,
Among the woods and copses lose themselves,
Nor with their green and simple hues disturb
The wild green landscape. Once again I see
Hedge-rows, then hardly hedge-rows, little lines
Of sportive wood run wild. These pastoral farms
Green to the very door, and wreathes of smoke
Sent up in silence from among the trees;
With some uncertain notice, as might seem,
Of vagrant dwellers in the fenceless woods;
Or of some hermit's cave, where by his fire
The hermit sits alone."

If such is the charm of local scenery, yet greater is the captivation of that individual and characteristic sentiment, which, from its appropriation to the drama, has been called dramatic. Such indeed is its enchantment, that it has been found capable of producing the most exquisite emotion, without any auxiliary embellishments from figurative language or picturesque imagery. We are never more delighted with the poet than when thus intimately admitted to his confidence, when we are suffered to commune with his heart, to explore his mostr etired thoughts, and partake his most sacred feelings. This charm of individuality was in some of his poems eminently possessed by Chaucer and some of our elder bards; it constituted the leading feature in Cowper's lays; it formed the magic of Burns; and it distinguishes the author of the Lyrical Ballads. The pathetic, like the sublime, must be concise and simple. It depends not so much on the thought as the expression. Virgil's description of Andromache on recognizing Æneas at the tomb of Hector, is strikingly beautiful:

"Verane tua facies? & verus mihi nuncius affers?
Nate deâ, vivisne? aut, si lux alma recessit,
Ubi Hector est?"

The whole passage is affecting, but the pathos dwells in the "ubi Hector est?" Figurative language is often happily employed in the description of impassioned feeling. Sometimes it appears to be the natural overflowing of tenderness:

"Thy cave should be a lover's bower,
Though raging winter rent the air;
And she a lovely little flower,
That I would tend, and shelter there."

In general, however, the simple and unadorned style is most appropriate to pathos and tenderness. Thus Constance, in her touching appeal to the Cardinals, exclaims of her son:

"And so he'll die; and rising so again,
When I shall meet him in the court of heaven
I shall not know him; therefore never, never,
Must I behold my pretty Arthur more."

The *curiosa felicitas*, that charm or felicity of expression which Horace so happily exemplified, is one of the most powerful agents in producing poetical emotion. It is the attribute which belongs only to the poet of nature; and is the effusion of some fortunate moments, when consummate judgment has been impelled and inspired by exquisite feeling. It is impossible but that the readers of Shakspeare and Milton must recollect innumerable examples of this kind of excellence. Who has not felt the enchantment conveyed by Shakspeare's "heaven-kissing hill?" What lover of nature has not in some bright autumnal morning, while contemplating a rural scene, experienced that mixed sensation of enjoyment and stillness which is all described in "the air smells wooingly?" Felicity of expression is the native idiom of genius; and as the goddess of beauty was discovered by her first movements, the genuine poet may be detected by a single epithet. The spirit of poetry is not confined to subjects of dignity and importance: it may be perceived in a simple lay, and even in a sportive song. It visited Sappho, as it had sojourned with Pindar; and was as truly the attendant of Theocritus as of Homer. Nor is poetical emotion inspired only by the song of heroes and of Gods. It may be awakened even by the strain of playful tenderness, in which the lover celebrates some darling of his mistress. The requisites of the true poetical character are thus happily summed up by the duke of Buckingham:

"'Tis not a flash of fancy, which sometimes,
Dazzling our minds, sets off the slightest rhymes,
Bright as a blaze, but in a moment done.
True wit is everlasting, like the sun,
Which, though sometimes behind a cloud retir'd,
Breaks out again, and is by all admir'd;
Number, and rhyme, and that harmonious sound
Which not the nicest ear with harshness wound,
Are necessary, yet but vulgar arts;
And all in vain these superficial parts
Contribute to the structure of the whole,
Without a genius too, for that's the soul;
A spirit which inspires the work throughout,
As that of nature moves the world about;
A flame that glows amid conceptions fit,
Even something of divine, and more than wit;
Itself unseen, yet all things by it shewn,
Describing all things, but describ'd by none."

POHLIA, a genus of the class and order cryptogamia musci, included in the bryonia of Linnæus.

POINCIANA, *Barbadoes flower-fence*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is pentaphyllous; the petals five, the uppermost larger than the rest; the stamina long, and all fertile; the seed-vessel a legumen. There is only one species, viz. the pulcherrima, a native of both Indies. It rises with a straight stalk 10 or 12 feet high; the branches are terminated by loose spikes of flowers, which are sometimes formed into a kind of pyramid, and at others disposed more in the form of an umbel. The foot-stalk of each flower is near three inches long; the flower is composed of five petals, which are roundish at the top, but are contracted to narrow tails at the base. They spread open, and are beautifully variegated with a deep red or orange colour, yellow, and some spots of green; and emit a very agreeable odour. After the flower is past, the germen becomes a broad flat pod three inches long, divided into three or four cells by transverse partitions, each including one flattish irregular seed. The plant is propagated by seeds; but, being tender, is to be constantly kept in the bark-stove.

POINT, in geometry, as defined by Euclid, is a quantity which has no parts, or which is indivisible. Points are the ends or extremities of lines. If a point is supposed to be moved any way, it will, by its motion, describe a line.

Point *of contrary flexure*. See Flexure.

Point, in music. This word, as conjoined with others, has various significations. The different uses to which points were formerly applied, render the perusal of old compositions extremely difficult and perplexing. In those works we meet with the point of perfection, point of augmentation, point of division, and point of alteration. The point of perfection was added to those notes which were denoted by the modal signs to be perfect, or equal to three notes of the same value, but which were rendered imperfect by position. The point of augmentation is that in modern use, which the old masters used only in common, or imperfect, time. The point of division, or imperfection, was placed between two shorter notes that followed, and were succeeded by, two longer in perfect modes, to render both the long notes imperfect. The point of alteration, or of duplication, was placed before two shorter notes preceding a longer, in order to double the length of the second short note. In modern music, the point, taken as an increased power of the note, is always equal to the half of the note to which it appertains.

Point, in astronomy, a term applied to certain points or places, marked in the heavens, and distinguished by proper epithets. The four grand points or divisions of the horizon, viz. the east, west, north, and south, are called the cardinal points. See Horizon, East, West, &c. The zenith and nadir are the vertical points; the points wherein the orbits of the planets cut the plane of the ecliptic, are called the nodes: the points wherein the equator and ecliptic intersect, are called the equinoctial points; particularly, that whence the sun ascends towards the north pole, is called the vernal point; and that by which he descends to the south pole, the autumnal point. The points of the ecliptic, where the sun's ascent above the equator, and descent below it, terminate, are called the solstitial points; particularly the former of them, the estival or summer point; the latter, the brumal or winter point.

Points, in heraldry, are the several different parts of an escutcheon, denoting the local positions of any figure. See Heraldry.

Point is also an iron or steel instrument, used with some variety in several arts. Engravers, etchers, cutters in wood, &c. use points to trace their designs on the copper, wood, stone, &c. See Engraving, &c.

Point, in the manufactories, is a general term, used for all kinds of laces wrought with the needle; such are the point de Venice, point de France, point de Genoa, &c. which are distinguished by the particular economy and arrangement of their points.

Point-Blank, in gunnery, denotes the shot of a gun levelled horizontally.

POINTING *the cable*, in the sea-language, is untwisting it at the end, lessening the yarn, twisting it again, and making all fast with a piece of marline, to keep it from ravel ing out.

POISONS. Poisons are commonly divided into the animal, vegetable, and mineral kinds.

I. Poisons, *animal*. Several animals are furnished with liquid juices of a poisonous nature, which when poured into fresh wounds, occasion the disease or death of the wounded animal. Serpents, bees, scorpions, and spiders, are well-known examples of such animals. The chemical properties of these poisonous juices deserve peculiar attention; because it is only from such an investigation that we can hope to explain the fatal changes which they induce on the animal economy, or to discover an antidote sufficiently powerful to counteract their baneful influence. Unfortunately the task is difficult, and perhaps surpasses our chemical powers. For the progress already made in the investigation, we are indebted almost entirely to the labours of Fontana.

1. The poison of the viper is a yellow liquid, which lodges in two small vesicles in the animal's mouth. These communicate by a tube with the crooked fangs, which are hollow, and terminate in a small cavity. When the animal bites, the vesicles are squeezed, and the poison forced through the fangs into the wound. This structure was partly observed by Redi, an Italian philosopher; and his discoveries were completed and confirmed by the experiments and observations of Francini, Tysson, Mead, and Fontana.

This poisonous juice occasions the fatal effects of the viper's bite. If the vesicles are extracted, or the liquid is prevented from flowing into the wound, the bite is harmless. If it is infused into wounds made by sharp instruments, it proves as fatal as when introduced by the viper itself. Some of the properties of this liquid were pointed out by Mead; but it was Fontana who first subjected it to a chemical examination, sacrificing many hundred vipers to his experiments. The quantity contained in a single vesicle scarcely exceeds a drop.

It has a yellow colour, has no taste; but when applied to the tongue, occasions numbness. It has the appearance of oil before the microscope, but it unites readily with water. It produces no change on vegetable blues.

When exposed to the air, the watery part gradually evaporates, and a yellowish-brown substance remains, which has the appearance of gum arabic. In this state it feels viscid, like gum, between the teeth; it dissolves readily in water, but not in alcohol; and alcohol throws it down in a white powder from water. Neither acids nor alkalies have much effect upon it. It does not unite with volatile oils, nor sulphuret of potass. When heated, it does not melt, but swells, and does not inflame till it has become black. These properties are similar to the properties of gum, and indicate the gummy nature of this poisonous substance. Fontana made a set of experiments on the dry poison of the viper, and a similar set on gum arabic, and obtained the same results.

From the late observations of Dr. Russel, there is reason to believe that the poisonous juices of the other serpents are similar in their properties to those of the viper.

This striking resemblance between gums and the poison of the viper, two substances of so opposite a nature in their effects upon the living body, is a humiliating proof of the small progress we have made in the chemical knowledge of these intricate substances. The poison of the viper, and of serpents in genenal, is most hurtful when mixed with the blood. Taken into the stomach, it kills if the quantity is considerable. Fontana has ascertained that its fatal effects are proportional to its quantity, compared with the quantity of the blood. Hence the danger diminishes as the size of the animal increases. Small birds and quadrupeds die immediately when they are bitten by a viper; but to a full-sized man the bite seldom proves fatal.

Ammonia has been proposed as an antidote to the bite of the viper. It was introduced in consequence of the theory of Dr. Mead, that the poison was of an acid nature. The numerous trials of that medicine by Fontana robbed it of all its celebrity; but it has been lately revived and recommended by Dr. Ramsay as a certain cure for the bite of the rattlesnake.

2. The venom of the bee and the wasp is also a liquid contained in a small vesicle, forced through the hollow tube of the sting into the wound inflicted by that instrument. From the experiments of Fontana, we learn that it bears a striking resemblance to the poison of the viper. That of the bee is much longer in drying when exposed to the air than the venom of the wasp.

3. The poison of the scorpion resembles that of the viper also; but its taste is hot and acrid, which is the case also with the venom of the bee and the wasp.

4. No experiments upon which we can rely have been made upon the poison of the spider tribe. From the rapidity with which these animals destroy their prey, and even one another, we cannot doubt that their poison is sufficiently virulent.

II. Poisons, *vegetable*, seem in general to prove fatal from an excess of narcotic matter; but this is a subject which requires still farther examination. See Narcotic principle.

III. Poisons, *mineral*. In general these substances, as arsenic and corrosive mercury, seem to attack the solid parts of the stomach, and to produce death by eroding its substance; but the antimonials seem rather to attack the nerves, and to kill by throwing the whole system into convulsions.

Poison *of copper*. This metal, though when in an undissolved state it produces no sensible effects, becomes exceedingly active when dissolved; and such is the facility with which the solution is effected, that it becomes a matter of some consequence to prevent the metal from being taken into the human body even in its proper form. It does not, however, appear that the poison of copper is equally pernicious with those of arsenic or lead. The reason of this is, that it excites vomiting so speedily as to be expelled, even though taken in considerable quantity, before it has time to corrode the stomach. Blue vitriol, which is a solution of copper in the vitriolic acid, has been used as a medicine in some diseases with great success. Verdigris also, which is another very active preparation of the metal, has been by some physicians prescribed as an emetic, especially in cases where other poisons had been swallowed, in order to procure the most speedy evacuation of them by vomit. Where copper is not used with this view, it has been employed as a tonic and antispasmodic, with which view it is admitted into the Edinburgh Dispensatory under the title of cuprum ammoniacale. The effects of the metal, however, when taken in a pretty large quantity, and in a dissolved state, or when the stomach abounds with acid juices sufficient to dissolve it, are very disagreeable, and even dangerous; as it occasions violent vomitings, pains in the stomach, faintings, and sometimes convulsions and death. The only cure for these symptoms is, to expel the poison by vomiting as soon as possible, and to obtund its acrimony; for which purpose drinking warm milk will probably be found the most efficacious remedy. In order to prevent the entrance of the poison into the body, no copper vessels should be used in preparing food but such as are either well tinned, or kept exceedingly clean. The practice of giving a fine blue or green colour to pickles by preparing them in copper vessels, ought not to be tolerated; for Dr. Falconer, in a treatise on this subject, assures us, that these are sometimes so strongly impregnared by this method of preparing them, that a small quantity of them will produce nausea. Mortars of brass or bell-metal ought, for the same reason, to be avoided; as by this means a considerable quantity of the pernicious metal may be mixed with our food, or with medicines. In other cases, an equal caution ought to be used. The custom of keeping pins in the mouth, of giving copper halfpence to children to play with, &c. ought to be avoided; as thus a quantity of the metal may be insensibly taken into the body, after which its effects must be uncertain. It is proper to observe, however, that copper is much more easily dissolved when cold than when hot; and therefore the greatest care should be taken never to let any thing designed for food, even common water, remain long in copper vessels when cold; for it is observed, that though the confectioners can safely prepare the most acid syrups in clean copper vessels without their receiving any detriment whilst hot, yet if the same syrups are allowed to remain in the vessels till quite cold, they become impregnated with the pernicious qualities of the metal.

Poison *of lead*. This metal, when taken slowly into the stomach with our food, is capable of producing the disease usually called Devonshire colic, which, after a length of time, is succeeded by palsy. Dr. Houlston, in his Essay on Poisons, has given a remarkable instance of a whole family who, having successively fallen a prey to paralytic disorders, after a series of years, the cause was discovered to be their having used the water of a leaden pump, which had been gradually dissolved, and thus rendered the water poisonous. For the treatment of colic and palsy see MEDICINE. Calomel administered in small doses, till ptyalism is produced, is the most effectual way of restoring sensibility to the nerves, when lost from this cause.

We cannot sufficiently express our abhorrence of the cruel, the detestable experiments made by certain practitioners upon poor dumb creatures, to ascertain the effects of poisons; experiments made in general to gratify an idle curiosity, but which no motive can justify. We feel an honest pride in reflecting that few of these experimentalists have been Englishmen; and as our work is addressed to that generous and humane nation, we have not outraged their feelings by the shocking detail.

POLE, in spherics, a point equally distant from every part of the circumference of a great circle of the sphere, as the centre is in a plane figure; or it is a point 90° distant from the plane of a circle, and in a line, called the axis, passing perpendicularly through the centre. The zenith and nadir are the poles of the horizon; and the poles of the equator are the same with those of the sphere. See GLOBE.

POLES. See ECLIPTIC.

POLES. See MAGNETISM.

POLE or *vertex of a glass*, in optics, is the thickest part of a convex, or the thinnest of a concave glass. If the glass is truly ground, the pole will be exactly in the middle of its surface.

POLE, *Perch*, or *Rod*, in surveying, is a measure containing sixteen feet and a half.

POLE or *polar star*, is a star of the second magnitude, the last in the tail of ursa minor. Its longitude Mr. Flamsteed makes 24° 14′ 41″; its latitude 66° 4′ 11″.

POLE-CAT. See VIVERRA.

POLEMONIUM, *Greek valerian*, or *Jacob's ladder*; a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. The corolla is quinquepartite; the stamina inserted into scales, which close the bottom of the corolla; the stigma is trifid; the capsule bilocular superior. There are five species, of which the most remarkable is the cæruleum, with an empalement longer than the flower. It grows naturally in some places of England: its beauty, however, has obtained it a place in the gardens. There are three varieties; one with a white, another with a blue, and another with a variegated flower; also a kind with variegated leaves. They are easily propagated by seeds; but that kind with variegated leaves is preserved by parting its roots, because the plants raised from seeds would be apt to degenerate and become plain.

POLEMOSCOPE, in optics, a kind of reflecting perspective-glass invented by Hevelius, who commends it as useful in sieges, &c. for discovering what the enemy is doing, while the spectator lies hid behind an obstacle. Its description is this: The interval between the object-glass and the speculum, is enlarged by a tube, of a length sufficient to project the speculum beyond the obstacle that covers the observer. And for a further convenience of looking forward, as it were, he proposes to place another plane speculum at the other end of the tube, to reflect the rays through a hole in its side, in a direction parallel to the incident rays; and to place the concave eye-glass in this hole. By this means, the object will still appear upright, and magnified just as much as if the two speculums were removed, and the same eye-glass was placed in the axis of the tube.

POLIANTHES, the *tuberose*: a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 10th order, coronariæ. The corolla is funnel-shaped, incurvated, and equal; the filaments are inserted into the throat of the corolla, in the bottom of which the germen is situated. There is but one species, consisting of some varieties; all of which, being exotics of tender quality, require aid of artificial heat, under shelter of frames and glasses, &c. to bring them to flower in perfection in this country. The varieties are the common tuberose, with single flowers; double-flowered, dwarf-stalked, variegated-leaved. They all flower here in June, July, and August: the flowers are funnel or bell-shaped; on the upper part of the stem is a long spike, consisting of from 10 to 20 or more separate in alternate arrangements, the lower flowers opening first, which are succeeded by those above, in regular order, making in the whole a most beautiful appearance, highly enriched with a most fragrant odour. The common single-flowered tuberose is the sort the most commonly cultivated, as it generally blows the most freely, and possesses the finest fragrance. The double-flowered kind also highly merits culture, as when it blows fair it makes a singularly fine appearance. The dwarf and the variegated kinds are inferior to the other two, but may be cultivated for variety. All the varieties being exotics from warm countries, although they are made to flower in great perfection in our gardens by the assistance of hotbeds, they will not prosper in the open ground, and do not increase freely in England; so that a supply of the roots is imported hither annually from Genoa, and other parts of Italy. The principal season for planting them is March and April: observing, however, that in order to continue a long succession of the bloom, it is proper to make two or three different plantings, at about a month interval; one in March, another in April, and a third the beginning of May, whereby the bloom may be continued from June until September; observing, as above mentioned, they may be flowered either by aid of a common dung or bark hotbed, or in a hot-house.

POLICY OF ASSURANCE. The deed or instrument by which a contract of assurance is effected. The premium or consideration paid for the risk or hazard assured against, must be inserted in the policy, and likewise the day, month, and year, on which the policy is executed, and it must be duly stamped. Policies for assurance against the risks of the sea are distinguished into valued and open policies; in the former the goods or property assured are valued at prime cost at the time of effecting the policy; in the latter, the value is not mentioned, but is left to be afterwards declared, or to be proved in the event of a claim. In a valued policy, the proper effect of the valuation is, the fixing the amount of the prime cost, in the same manner as if the parties had admitted it at a trial; but for every other purpose, it must be taken that the value was fixed in such a manner as that the insured meant to have an indemnity and no more. The practice of permitting the insured on a valued policy to recover the whole sum insured upon a total loss, though his interest is less than that sum, is against the statute. A valued policy on profits expected upon a voyage is not within the act, the object of an insurance being an indemnity. When a policy is once executed, it cannot be altered by either party, as this would open a door to an infinite variety of frauds, and introduce uncertainty into a species of contract, of which certainty and precision are the most essential requisites. If, however, a policy is filled up by mistake different from the original agreement, it may, even after signing, be corrected by the consent of both parties. An underwriter may, however, shift the insurance, or any part of it, from himself to other insurers, by causing a re-insurance to be made on the same risk, and the new insurers will be responsible to him, in case of loss, to the amount of the re-insurance; but the re-insurer is only responsible to the original insurer, and not to the original insured. The form of the policies in common use by the underwriters of London, for sea-assurances, is nearly the same which was adopted two hundred years ago; but Mr. Park remarks that its antiquity cannot preserve it from just censure, it being very irregular and confused, and frequently ambiguous, from making use of the same words in different senses. The policies generally used for assurances on lives, or against fire, are much more correct and intelligible.

POLIERSHIEFER, a mineral body found chiefly at Menil Montant, near Paris. Colour grey; often reddish; sometimes spotted or striped brownish-black, and lemon-yellow. Found in strata; texture earthy; fracture conchoidal; structure shistose; very soft; easily broken; adheres strongly to the tongue; feel harsh; specific gravity 2.08; absorbs water with avidity; melts to a blackish slag; constituents,

66.50	silica
7.00	alumina
1.50	magnesia
1.25	lime
2.50	oxide of iron
19.00	water.
97.75	

POLISHER, or *burnisher*, among mechanics, an instrument for polishing and burnishing things proper to take a polish. The gilders use an iron polisher to prepare their metals before gilding, and the blood-stone to give them the bright polish after gilding.

The polishers among cutlers, are a kind of wooden wheels made of walnut-tree, about an inch thick, and of a diameter at pleasure, which are turned round by the great wheel; upon these they smooth and polish their work with emery and putty.

The polishers for glass consist of two pieces of wood; the one flat, covered with old hat;

the other long and half-round, fastened on the former, whose edge it exceeds on both sides by some inches, which serve the workmen to take hold of, and to work backwards and forwards by.

The polishers used by spectacle-makers are pieces of wood a foot long, seven or eight inches broad, and an inch and a half thick, covered with old beaver-hat, on which they polish the shell and horn frames their spectacle-glasses are to be set in.

POLISHING, in general, the operation of giving a gloss or lustre to certain substances, as metals, glass, marble, &c.

The operation of polishing optic glasses, after being properly ground, is one of the most difficult points of the whole process. Before the polishing is begun, it is proper to stretch an even well-wrought piece of linen over the tool, dusting upon it some very fine tripoli. Then taking the glass in your hand, run it round forty or fifty times upon the tool, to take off the roughness of the glass about the border of it. This cloth is then to be removed, and the glass to be polished upon the naked tool, with a compound powder made of four parts tripoli mixed with one of fine blue vitriol; six or eight grains of which mixture are sufficient for a glass five inches broad. This powder must be wetted with eight or ten drops of clear vinegar, in the middle of the tool; being first mixed and softened thoroughly with a very fine small mullet. Then with a nice brush, having spread this mixture thinly and equably upon the tool, take some very fine tripoli, and strew it thinly and equably upon the tool so prepared; after which, take the glass to be polished, wiped very clean, and apply it on the tool, and move it gently twice or thrice in a straight line backwards and forwards; then take it off, and observe whether the marks of the tripoli, sticking to the glass, are equably spread over the whole surface; if not, it is a sign that either the tool or glass is too warm, in which case you must wait awhile and try again, till you find the glass takes the tripoli every where alike. Then you may begin to polish boldly, there being no danger of spoiling the figure of the glass, which in the other case would infallibly happen. This is Mr. Huygens's method; but it ought to be observed, that almost every operator has a peculiar one of his own, and of which some of them make a mighty secret.

Sir Isaac Newton no where expressly describes his method of polishing optical glasses; but his method of polishing reflecting metals he thus describes in his Optics. He had two round copper plates, each six inches in diameter, the one convex, the other concave, ground very true to one another. On the convex one he ground the object-metal, or concave which was to be polished, till it had taken the figure of the convex, and was ready for a polish. He then pitched over the convex very thinly, by dropping melted pitch upon it, and warming it, to keep the pitch soft, whilst he ground it with the concave copper wetted, to make it spread evenly all over the convex, till it was no thicker than a groat-piece; and after the convex was cold he ground it again, to give it as true a figure as possible. He then ground it with very fine putty, till it made no noise; and then upon the pitch he ground the object-metal with a brisk motion for two or three minutes; when laying fresh putty upon the pitch, he ground it again till it had done making a noise, and afterwards ground the object-metal upon the pitch as before; and this operation he repeated till the metal was perfectly polished.

POLITICAL ARITHMETIC, calculations relating to the wealth of nations. Political arithmetic does not determine in what national wealth truly consists, but estimates the value of whatever passes under this name, and distinguishes the proportions in which the component articles may be applied to purposes conducive to the safety or prosperity of the community. It must be admitted that in the application of arithmetic to the subjects of political economy, it unavoidably loses much of its precision, from the fluctuating nature of most descriptions of property, both with respect to distribution and value, the state of which it is one of its chief objects to estimate; it however retains a sufficient degree of certainty to become an interesting subject to every individual who wishes to acquire a just idea of the strength and resources either of the community to which he belongs, or of other nations.

If the particulars which it is necessary to assume as facts could be obtained correct, the conclusions drawn from them would be nearly as determinate and invariable as in any other branch of arithmetic; but if the former are not strictly true, the latter will be but approximations, however near they may come to the truth. Such approximations, however, may be sufficient for most useful purposes; though it must be confessed that a greater degree of certainty, which would render our knowledge on this subject more valuable, is highly desirable; at the same time it is difficult to attain, as it does not depend so much on the labours or investigations of individuals, as on the measures adopted by the governments of different countries, who alone possess the means of ascertaining with greater precision the principal assumptions on which political computations are founded.

The strict amount of the wealth of a country cannot be known without an exact inventory of all the particulars that compose it, a thing utterly impracticable in large, and particularly in commercial states, and which, if it were possible to be obtained perfectly true, even in the most minute particulars, would not remain so during the time necessary to make out the account, and therefore might not be of more utility than a tolerable correct estimate, which, being considered as a medium between small variations, will, for a considerable time, furnish sufficient ground for useful conclusions. So far, indeed, are we from having exact accounts of the wealth of different countries, that even such of the materials necessary to form an estimate as we do possess, though furnished pursuant to legislative authority, are scarce, in any instance, strictly correct, and being generally formed for particular purposes, as, with a view to some commercial or financial regulation, are frequently ill adapted to any other use: from such documents, however, we must be content to draw our principal information; and if the nature of the subject precludes strict demonstration, we may, at least, endeavour, by proceeding on rational grounds, to arrive at conclusions consistent with probability.

Political arithmetic has been much cultivated of late years in Germany, France, and other parts of Europe, but as its application to the wealth and strength of different states is very similar, we shall endeavour to illustrate it in an attempt to determine the increase and present state of the national wealth of Great Britain, which will be considered as consisting in the value of the land and of the stock, the latter term comprehending all useful realizations of past industry, except improvements of the soil, which make part of the present value of the land; and if the amount of the national capital can be ascertained, it will naturally lead to an investigation of the general income, both as arising from such capital, and from the profits of labour.

In all inquiries of this kind, the state of the population of the country is an object of primary importance; for it is the number of inhabitants which a country maintains, that gives the land itself the chief part of its value, of which we have many proofs in the former and present state of different parts of Europe, and in the rise of the value of land with the increase of population in our own island. That Great Britain is now more fully inhabited than in the early periods of its history, few persons will doubt, whatever may be their opinion respecting its advance or decline in this respect of late years. At the time of the Norman conquest, the people of England are supposed to have been somewhat above 2,000,000; and from their depressed condition, the frequency of foreign and domestic wars, and of pestilential distempers, their increase during many of the succeeding reigns may be reasonably doubted, though there are no means of ascertaining with any precision the real state of the population at those periods. From an account of the produce of a poll-tax, an estimate has been formed by Mr. Chalmers of the number of inhabitants in 1377, and as the additions which he has made to the number in the return certainly do not appear too small, the total, which amounts to 2,353,203, cannot be less than the whole number of the people of England and Wales at that time, if the account on which it is founded is to be depended on. Mr. Chalmers observes, that the civil wars during the greater part of the fifteenth century must have caused a great waste of inhabitants: this loss, however, was soon recovered on their termination; and the suppression of monasteries by Henry the VIIIth, with the repeal of all positive laws against the marriage of priests by Edward the VIth, continued to promote matrimony, and of course to increase the population. From documents in the British Museum, it appears, that during the reign of Elizabeth, accounts were often taken of the people. Harrison gives the result of the musters of 1575, when the number of fighting men was found to be 1,172,674, adding that it was believed a full third had been omitted. Sir Walter Raleigh asserts that there was a general review in 1583 of all the men in England capable of bearing arms, who were found to amount to 1,172,000. These accounts evidently refer to the same enumeration, though they differ in the date; and if the number is multiplied by 4, it would prove the total number of inhabitants to have been 4,688,000. This number increased during the seventeenth century, and was computed by Mr. Gregory King to amount in 1690 to 5,500,000; while Dr. Davenant estimated the population at the same period as high as 7,000,000. This disagreement between two very accurate writers, shews the great uncertainty which prevailed on this subject, and in fact there was scarce any particular relating to the state of the country on which such opposite opinions were held as on the actual number of inhabitants at particular periods, and their diminution or increase. The point has at length been determined by the results of an act passed the 31st of December, 1800, for ascertaining the population of Great Britain, and the increase or diminution thereof. From the returns thus obtained, it appeared, that the total population of Great Britain, including the army and navy, and seamen in the merchants' service, was 10,942,646; but deducting the proportion of soldiers and seamen belonging to Ireland, it may be more correctly stated at 10,820,370.

Assuming this number as a sufficiently accurate return of the total population, it may not be very difficult to distinguish nearly the proportion of those who subsist by the labour of others, to those by whom they are supported; and of the unproductive, though in most instances useful, labourers, to those on whose labour the annual produce, and consequently all additions to the national stock, depends.

From several accounts it appears, that, of the whole number of persons living, more than one-fourth are children under ten years of age, who therefore contribute little or nothing to their own maintenance; for though in some few manufactures, children under this age are employed, they are more than counterbalanced by the greater number who remain unemployed (otherwise than in education) for several years beyond the age of ten. After deducting 2,705,092, the number of these future labourers, it will be found that about one in 28 of the remainder, or 289,831 are incapacitated by old age or infirmities from useful labour, including all persons in the different hospitals and infirmaries, and most of the inhabitants of alms-houses, and other charitable establishments. But of those who are supported by the labour of others, or by the property of others, which is equivalent, there are many who follow a species of employment, by which they obtain this property, which employment is, however, of no benefit to the country, as it is not only unproductive, but useless, and in many instances injurious to the community; such are gamblers, swindlers, thieves, prostitutes, beggars, gipsies, &c. whose aggregate number, according to Mr. Colquhoun's estimate for the metropolis, probably exceeds considerably 150,000. The convicts and prisoners confined in the different prisons of Great Britains, and on board hulks, are usually about 10,000 persons, whose labour is lost to the community, for the work which is performed in some of our jails scarcely deserves mention. There is also a class of a very different description, who are supported by the labour of others: this is the nobility and gentry, whose exemption from labour is considered as a part of their honour and distinction; some, it is true, hold employments under the government, and a few are engaged in agriculture or trade; but the majority, who subsist on the income they possess, without following any useful occupation, is probably not less than 5000.

These numbers include persons of both sexes, and are all rather below the truth than beyond it; they amount together to 3,159,923 persons, and being deducted from the whole population of 10,820,370, shew the number of those who work to be 7,660,447. But it is well known that of those who gain a substance by their labour, many follow employments which, though more or less necessary and useful, do not, in the least degree, increase the quantity or value of the produce of the country; the number of these unproductive labourers is nearly as follows:

The army, officers and privates, including half-pay, commissaries, agents, &c.	200,000
The navy, ditto	127,000
Officers and clerks employed in collecting the revenue, and in other offices under government	6,500
Clergy of the churches of England and Scotland	18,000
Ditto, dissenters of every denomination	14,000
Schoolmasters (exclusive of clergymen) and schoolmistresses	20,000
Judges, counsel, attorneys, sheriff's officers, jailors, and all persons employed in the execution of the laws, except constables, headboroughs, &c.	14,000
Players, musicians, dancing masters, &c.	5,000
Women supported by their husbands' labour	500,000
Female servants of all descriptions	650,000
Male servants	150,000
Total	1,704,500

It must be confessed that the number of some of these classes of persons cannot be ascertained with much precision: this, however, is of no great importance, if the total is not far from the truth, as the object is chiefly to shew the proportion of productive to unproductive labourers; the latter may be distinguished according to the following statement:

Merchants, brokers, factors, and others depending on foreign trade	25,000
Clerks to ditto, and in the offices of commercial companies	40,000
Seamen in the merchants' service, including the coasting-trade and fisheries	144,000
Lightermen, watermen, &c.	3,500
Persons employed in the different manufactures	1,800,000
Mechanics not immediately belonging to the manufactures, such as carpenters, bricklayers, masons, wheelwrights, shipwrights, boatbuilders, &c.	50,000
Painters, engravers, carvers, and other artists	5,000
Shopkeepers, viz. butchers, bakers, publicans, fishmongers, poulterers, pastrycooks, grocers, chandlers, pawnbrokers, apothecaries, &c.	150,000
Farmers, graziers, and all other persons employed in agriculture, including millers, mealmen, farriers, horse-doctors, &c.	2,000,000
Wives and families of most of the above classes assisting in their occupations, or following other employments of profit	1,738,447
Total	5,955,947

The whole population of the country will thus appear to consist of nearly the following proportions:

Supported by others' labour	3,159,923
Unproductive labourers	1,704,500
Productive labourers	5,955,947
Total	10,820,270

It thus appears that the whole of the people depend for subsistence, and all the conveniences of life, on the labour of little more than one-half; and the increase or decrease of this number, and of the effect produced by the individuals who compose it, is the measure of the increase or decline of national strength. Of the unproductive labourers, or those who gain a subsistence by defending, instructing, or serving others, the greater part are highly useful to the community, and in the present state of society a nation could not exist without them; but as they do not contribute to the production of any of the necessaries of life, or articles of commerce, it is evident that they depend entirely on the exertions of the productive labourers, who are the source not only of the general subsistence and of the means of commerce, but of all accumulation of stock, which is in fact the surplus of former produce beyond the consumption. The power of acquiring national wealth, therefore, depends principally on the proportion of productive labourers to the whole number of inhabitants; for though the population of a country should have greatly increased, if it had been chiefly by an addition of idle hands, the produce would remain the same, and, the consumption being much greater, the country must become poorer: but it likewise depends, in a great measure, on the facility with which labour is performed; for if a country contained only half the number of labouring inhabitants, with the same number of other persons it had at a former period, but this half, by means of machinery and other improvements, could produce the same effect as the whole number before, such a country would become considerably richer, though the total population was diminished, and the proportion of unproductive to productive persons increased; for there would be the same supply and a much less consumption: and wherever the produce or supply exceeds the consumption, there will be an acquisition of stock; for, unless the surplus could be reserved for some useful or desirable purpose, it would soon cease to be produced, by the supply falling to the level of the demand for consumption. The surplus reserved or converted into stock, is a fund for supporting an increase of exertion, or for supplying the means of future enjoyment.

It has been shewn, that the whole number of the inhabitants of Great Britain is undoubtedly greater than at former distant periods; but the proportion of unproductive hands, who subsist by the labour of others, has also probably much increased; the effect of this unfavourable circumstance has however been amply compensated by the great improvements in different arts and manufactures, by which the produce of the country has been increased in quantity, and rendered much superior in quality; so that after supplying all our new factitious wants, and enabling us to defray expensive wars, it has left a considerable surplus, which, gradually accumulating, has formed the present national stock or capital.

Previously to an inquiry into its increased amount, it may not be uninteresting to view its former computed value, according to the estimate of sir William Petty, who certainly cannot be suspected of having drawn an unfavourable statement:

Computation of the wealth of England and Wales in 1664.

	£
Value of the land: 24 millions of acres, yielding 8 millions per ann. rent, worth at 18 years purchase - -	144,000,000
Houses, reckoning those within the bills of mortality equal in value to one-third of the whole - -	30,000,000
Shipping: 500,000 tons, at 6*l.* per ton, including rigging, ordnance, &c. - -	3,000,000
Stock of cattle on the 24 million acres, and the waste belonging thereto, including parks, fisheries, warrens, &c.	36,000,000
Gold and silver coin, scarce -	6,000,000
Wares, merchandize, plate, furniture, &c. - -	31,000,000
Total - -	£ 250,000,000

In comparing this estimate with similar accounts at present, it must be remembered that a great alteration has gradually taken place in the nominal value of all commodities, which, with respect to the above period, appears, from a table formed by sir G. S. Evelyn, to be in the proportion of about five to fourteen; the total of the wealth of England and Wales, in 1664, would therefore have amounted to 700,000,000*l.*, according to the present value of money.

The value of land has progressively increased, in consequence of improvements in cultivation, and the increased consumption of the produce of land. Before England became a trading nation, the general price of land was twelve years purchase. At the beginning of the last century, it sold for about sixteen years purchase: sir W. Petty valued it at eighteen years purchase: and at the commencement of the last century, it had advanced to twenty years purchase. About the year 1730, it had risen to twenty-five years purchase; and at present is from twenty-eight to thirty years purchase. The increase of the number of years purchase paid for land, is the most obvious proof of its augmented value; but it does not shew the whole augmentation of the national wealth on this account, which in part arises from the increase of the total rental beyond the advance that is caused merely by the difference in the value of money. This real increase of the rental proceeds from a greater proportion

of land being brought into cultivation, and that which was before cultivated being improved. The whole landed rental of England and Wales, and the Lowlands of Scotland, was stated by sir W. Petty at about 9,000,000*l.*; and it cannot be supposed that, if he had included the Highlands of Scotland, he would have made the rental of the whole island more than 9,500,000*l.* G. King and Dr. Davenant, in queen Anne's reign, stated the rental of England and Wales at 14,000,000*l.*; and it may be presumed this was nearly the truth at the time: but it soon began to appear too low; and between twenty and thirty years ago it was generally reckoned at 20,000,000*l.* At present, however, it considerably exceeds this sum.

The chief difficulty of forming an estimate of the land rental consists in assigning an average value to the different descriptions of land. The total number of acres in England and Wales has been computed by sir W. Petty to be 28,000,000; by Dr. Grew, 46,000,000; by Dr. Halley, 39,938,500; by Mr. Templeman, 31,648,000; by Mr. Arthur Young, 46,916,000; and by the Rev. H. Beeke, 38,498,572. Mr. Beeke's calculation appears to be by far the most accurate: it is therefore taken as the foundation of the following statement; the proportions cultivated for different purposes being nearly as given by Mr. Middleton, in his View of the Agriculture of the County of Middlesex:

	Acres.
Wheat - - -	3,160,000
Barley and rye - -	861,000
Oats and beans - -	2,872,000
Clover, rye-grass, &c. -	1,149,000
Roots and cabbages cultivated by the plough - -	1,150,000
Fallow - - -	2,297,000
Hop-grounds - -	36,000
Nursery grounds - -	9,000
Fruit and kitchen-gardens, cultivated by the spade -	41,000
Pleasure-grounds - -	16,000
Land depastured by cattle -	17,479,000
Hedge-rows, copses, and woods	1,641,000
Ways, water, &c. - -	1,316,000
Cultivated land - -	32,027,000
Commons and waste lands -	6,473,000
Total acres in England and Wales	38,500,000

If the commons and waste lands are considered as equal in annual value to only one million of cultivated acres, the whole may be taken at 33 millions. The average rent has been stated at 15*s.* per acre, which appears to be a moderate computation, and makes the rental amount to 24,750,000*l.*, the value of which, at 28 years purchase, is 693,000,000*l.* The number of cultivated acres in Scotland is upwards of 9,690,000; and of uncultivated, about 11,310,000: a great part of the latter is of very little use; but if it is wholly excluded, and the cultivated part rated at an average of 10*s.* per acre, which makes 4,845,000*l.* per annum, the total rental of the island will be 29,595,000*l.*, and the value of the land 828,660,000*l.* This must be understood as including the value of tythes, it being unnecessary in this point of view to distinguish between the rent paid to the landlord, and the part paid to the tythe proprietor.

The value of the houses of Great Britain is perhaps more difficult to ascertain than that of the land: but the following statement of their rent, founded on the number returned under the population act, will not be thought too high:

100,000 houses,	at 30*l.* per ann.	£ 3,000,000
500,000	10*l.*	5,000,000
250,000	5*l.*	1,250,000
600,000	2*l.*	1,200,000
425,000	1*l.* 10*s.*	637,500
1,875,000	Total rent	£ 11,087,500

The total rent, if valued at only 18 years purchase, makes the value of all the houses in Great Britain 199,575,000*l.*

In order to form an idea of the value of cattle and farming-stock on the land, we may consider the black cattle and calves, sheep and lambs, swine, pigs, and poultry, annually consumed in London, as worth 6,000,000*l.*, which cannot be more than a seventh part of the whole consumption, amounting therefore in value to 42,000,000*l.*; but the whole number of cattle existing must be more than double the quantity brought to market; so that, including horses, asses, cows kept for milk, and oxen employed in agriculture, the whole value of the cattle cannot be less than 90,000,000*l.*

Taking the annual consumption of grain of all sorts at 16,000,000 quarters, which is probably below the truth, we may presume, that in general there is at least three or four months supply on hand, which, at only 35*s.* per quarter, will amount to at least 7,000,000*l.* The value of hay and straw, and all kinds of fodder, and of all implements of husbandry, cannot be less than five or six millions, and with the former sum cannot be less than 12,500,000*l.* The total value of cattle and farming-stock is therefore 102,500,000*l.*

The value of the shipping belonging to Great Britain may be calculated with more accuracy. It appears from the accounts laid before parliament, that exclusive of Ireland and the plantations, the number of vessels in the merchants' service, belonging to Great Britain, on the 30th September 1804, was 17,809; and the amount of their tonnage, 2,018,999 tons: taking it at 2,000,000, at 8*l.* per ton, it makes 16,000,000*l.*, which is certainly below the real value. The shipping of the navy may at least be estimated at 4,000,000*l.*; making with the former sum, 20,000,000*l.*; to which some addition should be made for the value of ships building in all the dock-yards, and for small craft employed on the rivers and canals.

The quantity of money in the country has at different times been a subject of dispute, and has never been determined with precision. It was, however, pretty well ascertained by the re-coinage in the years 1773, 1774, and 1776. The value of the light gold delivered into the bank under the different proclamations, amounted to 15,563,593*l.*; and it was generally admitted that somewhat more than two millions of heavy guineas remained out in circulation, which, with the silver and copper coin, made the whole at that time about 20 millions; at which sum Mr. Chalmers estimated it in the year 1786. Including the cash in the coffers of the bank it appears, that at the time of the re-coinage the whole money in the country was rather above than under the sum just stated: and from the sums annually coined since that time, it might be presumed that the quantity in circulation at present was considerably greater. Mr. Rose has stated it at no less than 44,000,000*l.*; but though our commerce has considerably increased, it will hardly be thought, considering the far greater quantity of small bank notes in circulation, that, if 20 millions of coin was sufficient in 1776 or 1786, we can at present have occasion for more than 25 millions at the utmost.

Of the value of the merchandize and manufactures usually in the hands of the merchants, wholesale dealers, shopkeepers, and manufacturers, it is very difficult to form a satisfactory idea. The total amount of the imports in the year 1804 was 29,201,490*l.*, and of the exports, 34,451,367*l.*, according to the custom-house accounts; but it has long been known that these accounts are considerably below the true value, and particularly since passing the convoy act, in the execution of which it has appeared that the declared value of British manufactures exported is about 71 per cent. greater than the value in the inspector-general's register; and, with respect to the foreign merchandize imported, the difference on the whole may not be much less; for it is certain that some of the articles are at present considerably more than 71 per cent. above the value at which they are rated. Taking the whole, however, as rated only 60 per cent. under the present values, the annual amount of foreign trade will be 101,844,571*l.*, to which some addition should be made for smuggled goods. It was the opinion of a numerous meeting of merchants in the year 1797, that there is at all times at the least two months supply of export and import merchandize in the custody of the merchants and traders, which, according to the above total, will amount to 16,974,095*l.*; to which some addition should be made for property in the hands of foreign merchants, on account of the merchants of this country generally giving longer credit than they are allowed from other countries. But though the value of goods in the hands of merchants and wholesale dealers appears so considerable, it must be exceeded by the goods in the hands of the manufacturers and of retail traders: for though many of our principal manufactures depend greatly on foreign trade, their main support is the home consumption. The official value of British produce and manufactures exported in the year 1804, was 23,935,793*l.*; but the real value, as far as it can be ascertained, amounted to 40,349,642*l.* This, it may be presumed, cannot be more than half of the whole produce of our manufactures, which will thus amount to 80,699,284*l.*, of which but a small proportion is included in the value before-mentioned in the hands of the merchants; which consists chiefly of foreign merchandize and materials for the different manufactures, as they can generally obtain manufactured goods for exportation at a short notice, deducting, however, 3,000,000*l.* on this account: of the remainder it is probable that there is much more than three months supply in the hands of the manufacturer, in different stages from the raw material to finished goods, and in the possession of retail traders, who, in many branches, are obliged to keep a large assortment; but taking it only in this proportion it amounts to 19,424,821*l.*

There still remains to be valued that part of the property of individuals which consists in household furniture, wearing apparel, plate, jewels and trinkets, books, provisions, fuel, carriages, &c.; with respect to which the most that can be done is to form a conjecture that shall be generally admitted as not exceeding the truth; and certainly this general kind of property, of which every individual must possess or enjoy the use of some share, will not be thought over-rated at three times the yearly rent of the houses which contain it, or 33,262,500*l.* in all Great Britain.

Having thus valued the different descriptions of stock, or actual capital, its total amount will appear as follows:

Value of the land of Great Britain - - -	£828,660,000
Houses - - -	199,575,000
Cattle, and all kinds of farming stock - - -	102,500,000
Shipping: navy and merchant ships - - -	20,000,000
Money - - -	25,000,000
Goods in the hands of merchants and wholesale dealers	16,974,000
Goods in the hands of manufacturers and retail traders	19,424,000
Furniture, apparel, &c. -	33,262,000
Total - -	£1245,395,000

Upon this capital all other species of wealth, whether consisting in the securities of government or individuals, or of any other description, ultimately depends; for private and public loans, in which mode a great part of the property of many persons is invested, implying an obligation on the part of the borrower to repay at a future period a certain sum of money which is the measure and representative of all other species of property, or to pay an income arising from this sum till the capital is repaid, the borrower is no otherwise richer than by the greater income he can make from the money than what he agrees to pay for it: as the capital, in whatever manner he invests it, still belongs to the lender, who, though he may not by the laws of the country be permitted to take possession of the property into which his money has been converted, may, if necessary, bring it to sale, for the purpose of re-converting it into the sum equivalent to what he had lent. If therefore, the whole of the land, houses, cattle, and all other articles composing the wealth of the country, was in the hands of one half of the inhabitants, who had borrowed the above sum of 1245,395,000*l.* from the other half, it is evident that the whole real capital of the country would in fact be the property, not of those in possession of it, but of those to whom they were indebted. This is the case with respect to a considerable part of the capital of Great Britain; and the debts of the government have greatly contributed to bring it into this state: for though these debts are not contracted under an obligation to repay the principal at any fixed period, they rest on the right which the government possesses, to claim, if it should ever be necessary, a portion of the general property sufficient for this purpose, and till that time to raise sufficient contributions to pay an annuity equivalent in value to such principal.

The above estimate shews, that, notwithstanding the expensive wars in which the country has been engaged, which, by drawing much money out of the country, has greatly diminished the profits that would otherwise have remained, there has been a great accumulation; though, at the same time, the people in general appear to live in a much more expensive manner than their ancestors. We have seen that in the year 1664, the whole national capital did not exceed 700,000,000*l.*, according to the present value of money: there has therefore been an average gain since that time of nearly four millions per annum, a very considerable part of which must have arisen from foreign commerce; for commerce would not be carried on without gain; and whatever profits have been saved or converted into stock, must appear in the foregoing account: even the increased value of the land and houses is in a great measure owing to the assistance of capitals acquired in trade.

The great increase of the annual income is a further proof that there must have been such an accumulating surplus as is here stated. Sir W. Petty computed the whole income of the country to be 42,000,000*l.*; Mr. G. King estimated it at 43,500,000*l.*; Dr. Davenant, in 1701, stated it at 49,000,000*l.* These accounts are exclusive of Scotland; but after making a sufficient addition on this account, it will appear that there has been a very considerable increase. Sir John Sinclair, in 1783, observed that the income of the country arising from lands, commerce, and manufactures, was commonly calculated at 100,000,000*l.*, which he considered rather a low valuation; and there can be little doubt that of late years the profit derived from each of these sources has been greatly augmented.

A part of the national stock or capital produces no income; such as the money in circulation, furniture, apparel, &c.; and on the contrary much income arises without capital, being solely the recompence of labour. A very considerable proportion arises from capital and labour united, such as that of most farmers, merchants, and retail traders, and the difficulty of distinguishing, in many cases, that part of the income of individuals which is the wages of their labour, from the part which should be considered as the profits of their capital, must render every attempt to particularize the amount of the different branches of income liable to objections. The following statement is, however, presumed to be not very inaccurate:

From rent of lands -	£29,595,000
From rent of houses - -	11,087,000
Profits of farming, or the occupation of the land - -	6,120,000
Income of labourers in agriculture - - -	18,000,000
Profits of mines, collieries, and inland navigation -	2,000,000
Profits of shipping in the merchants' service, and small craft	1,000,000
Income of stockholders -	18,925,000
From mortgages and other money lent on private securities	2,500,000
Carried over -	£89,227,000

Brought over -	£59,227,000
Profits of foreign trade -	11,250,000
Ditto of manufactures -	13,300,000
Pay of the army and navy, and seamen in the merchants' service - - -	5,500,000
Income of the clergy of all descriptions - -	2,200,000
Income of the judges, and all subordinate officers of the law	1,800,000
Professors, schoolmasters, tutors, &c. - - -	600,000
Retail trades not immediately connected with foreign trade, or any manufacture -	6,000,000
Various other professions and employments - -	2,000,000
Male and female servants -	2,000,000
Total -	£133,877,000

Of this annual sum, the part drawn from other countries by commerce is stated at 11,250,000*l.* which is founded on a supposition that the capital employed cannot be less than 75,000,000*l.*; and that the profits thereon, including those of all persons immediately depending on foreign trade, may be taken at 15 per cent. It must not, however, be supposed that the nation receives an accession of wealth to the amount of 11,250,000*l.* annually from this source: whatever payments are made to other countries for the dividends on the share foreigners hold of the public debts, or as subsidies to their governments, or spent therein in the maintenance of troops, or by British subjects occasionally resident there, operates to the diminution of this profit in a national view. The actual wealth which the country acquires by its intercourse with other nations, may be very different from the profits of the individuals concerned in trade; as a sum equal to a great part, or even the whole, of such profits, may be sent abroad in the various ways just mentioned. The balance of trade in favour of the country has usually been estimated by the excess of the exports beyond the imports, and a comparatively small amount of the latter has been considered highly desirable. This is a concise mode of determining a very important point. But even if the customhouse accounts were much better adapted to the purpose than they are, the justness of the conclusions thus drawn from them would be very doubtful: for it may be easily shewn that in many cases, if the imports even exceeded the exports, there might notwithstanding be a considerable gain. Thus, supposing the merchants of this country to purchase British manufactures for exportation on their own account, to the value of 20,000,000*l.*, the net proceeds thereof in the countries to which they are exported cannot be considered as less than 22,000,000*l.*; and this sum being invested in foreign produce, and imported into this country, will amount, after repaying the duties and all expences, to at least 24,200,000*l.*, returning the merchants the capital originally advanced, with a profit of 21 per cent. In like manner, whenever the merchandize imported in return for any quantity exported is of greater actual value in this country, or yields a greater price, after allowing for all charges and the interest of the capital employed, the surplus must be an addition to the wealth of the country; and if the whole of the foreign trade was of this description, the excess of the imports would shew the profit or the wealth acquired by the exchange of commodities with other nations.

It has been shewn, that the total income of the country is at present upwards of 133,000,000*l.*; and that it cannot be less than this sum, may be inferred from the general expenditure. Sir W. Petty reckoned the average expence of men, women, and children, in England and Wales, at 6*l.* 13*s.* 4*d* per annum, for food, housing, clothes, and all other necessaries; Dr. Davenant took the average expence at 7*l.*, which, according to the difference in the value of money, is equal to upwards of 16*l.* for each person at present. Mr. Jonas Hanway, about 35 years ago, estimated the expence of the people of England and Wales on an average about 9*l.* each; but this must be too low at present: and the following estimate will probably approach nearer to the truth, with respect to the mere expence of subsistence, or of eating and drinking, particularly as we are not to consider what is absolutely necessary for support, but what is actually expended in this way:

Persons.			
300,000	at 16*d.* per day		£7,300,000
700,000	12*d.*	-	12,775,000
1,500,000	9*d.*	-	20,531,250
2,000,000	6*d.*	-	18,250,000
2,500,000	4*d.*	-	15,208,333
2,000,000	2*d.*	-	6,083,333
1,500,000	1*d.*	-	2,281,249
10,500,000			£82,429,165

When the price of most of the necessaries of life is considered, it will not be thought that the expence of subsistence is over-rated in the lowest classes; and if this is admitted, it cannot be too high in the other classes, when it includes strong beer, spirits, wine, and a variety of luxuries. To the expences of living must be added those of house-rent, clothing, and superfluous expences, in order to arrive at the whole actual expenditure. The first of these articles has been stated at 11,087,500*l.*; and allowing for the rent of shops, warehouses, and other buildings appropriated wholly to trade, it may be taken at 9,500,000*l.* The expence of clothing, including every article of dress, or personal decoration, will, on a very moderate computation, amount to 26 millions, viz.

150,000 persons	at 20*l.* per an.	£3,000,000
300,000	12*l.*	3,600,000
750,000	8*l.*	6,000,000
1,300,000	4*l.*	5,200,000
2,800,000	30*s.*	4,200,000
4,000,000	20*s.*	4,000,000
1,500,000	0	
10,800,000		£26,000,000

With respect to superfluous expences, when the sums spent by the nobility and people of fashion in plays, operas, concerts, routs, gambling, horses, carriages, and other amusements and luxuries, are considered, it will certainly be thought a very moderate assumption, that, including what is spent by others on objects more rational, though not absolutely requisite, there are half a million of persons who, one with another, spend 25*l.* per annum in unnecessary expences, making 12,500,000*l.* The total expence will then be:

For subsistence - -	£82,400,000
For house-rent - -	9,500,000
For clothing - -	26,000,000
For miscellaneous expences -	12,500,000
Total -	£130,400,000

The difference between this expenditure and the general income shews the annual gain of the country, or the sum applicable to the extension of commerce, the reservation of a greater quantity of foreign articles, the increase of shipping and buildings, agricultural or mechanical improvements, or other augmentations of the general stock. Without such a surplus, few improvements could be carried on, nor could there be any increase of wealth; and if this latter circumstance is thought essential to national advancement, it becomes an object of much importance, that the expences of the government should be restrained within such bounds, and provided for in such manner, as to intrench as little as possible on the annual surplus that would otherwise be converted into permanent capital.

POLIUM, *poley-mountain*, in botany, a species of teucrium, with oblong, obtuse, crenated, and sessile leaves. See TEUCRIUM.

POLL, a word used in antient writings for the head: hence to poll is either to vote or to enter down the names of those persons who give in their votes at an election.

POLL-MONEY, a capitation or tax imposed by the authority of parliament on the head or person either of all indifferently, or according to some known mark of distinction.

POLLIA, a genus of the class and order hexandria monogynia. The corolla is inferior, six-petalled; berry many-seeded. There is one species, an herbaceous plant of Japan.

POLLICHIA, a genus of the monandria monogynia class and order. The calyx is one-leafed, five-toothed; corolla, five petals; seed solitary; receptacle succulent, aggregate scales. There is one species, of the Cape.

POLLUX, in astronomy, a fixed star of the second magnitude in the constellation Gemini, or the Twins. See ASTRONOMY.

POLYADELPHIA (from πολυς, *many*, and αδελφια, *brotherhood*), many brotherhoods; the name of the 18th class of Linnæus's sexual system, consisting of plants with hermaphrodite flowers, in which several stamina or male organs are united by their filaments into three or more distinct bundles.

POLYANDRIA (from πολυς, *many*, and ανηρ, a *man* or *husband*), many husbands; the name of the 13th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with several stamina that are inserted into the common receptacle of the flower.

POLYCARDIA, a genus of the class and order pentandria monogynia. The petals are five; stigma lobed; capsules five-celled; seeds arilled. There is one species, a shrub of Madagascar.

POLYCARPON, a genus of the class and order triandria trigynia. The calyx is five-leaved; petals five; capsule one-celled; seeds many. There is one species.

POLYCNEMUM, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is triphyllous; and there are five calciform petals, with one seed almost naked. There are five species, of no note.

POLYGALA, *milkwort*, a genus of the octandria order, in the diadelphia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is pentaphyllous, with two of its leaflets wing-shaped and coloured; the legumen is obcordate and bilocular. There are 45 species, of which the most remarkable are:

1. The vulgaris, or common milkwort, is a native of the British heaths and pastures. The root of this plant has a bitter taste, and has been found to possess the virtues of the American rattlesnake root. It purges without danger, and is also emetic and diuretic; sometimes operating all the three ways at once. A spoonful of the decoction made by boiling an ounce of the herb in a pint of water till one-half has exhaled, has been found serviceable in pleurisies and fevers, by promoting a diaphoresis and expectoration; and three spoonfuls of the same taken once an hour, has proved beneficial in the dropsy and anasarca. It has also been found serviceable in consumptive complaints.

2. The senega, or seneka, rattlesnake-wort, grows naturally in most parts of North America. The root of this species operates more powerfully than the last; but besides the virtues of a purgative, emetic, and diuretic, it has been recommended as an antidote against the poison of a rattlesnake; but this opinion is now exploded. It still, however, maintains its character in several disorders. Its efficacy, particularly in pleurisies, is most fully established in Virginia: formerly near fity out of one hundred died of that distemper; but by the happy use of this root hardly three out of the same number have been lost.

As the seeds of the rattlesnake-wort seldom succeed even in the countries where the plant is a native, the best method of propagating it is to procure the roots from America, and plant them in a bed of light earth in a sheltered situation, where they will thrive without any other culture than keeping them free from weeds. But though the plant will stand out ordinary winters, it will be proper to cover it during that season with old tanner's bark, or other mulch, to keep out the frost.

POLYGAMIA (πολυς, *many*, and γαμος, *marriage*). This term, expressing an intercommunication of sexes, is applied, by Linnæus, both to plants and flowers. A polygamous plant is that which bears both hermaphrodite flowers and male or female, or both.

POLYGAMY, the plurality of wives or husbands, in the possession of one man or woman, at the same time. By the laws of England, polygamy is made felony, except in the case of absence beyond the seas for seven years; and where the absent person is living in England, Wales, or Scotland, and the other party has notice of it, such marrying is felony by the statute 1 Jac. I. c. 11.

POLYGLOTT, among divines and critics, chiefly denotes a bible printed in several languages. In these editions of the holy scriptures, the text in each language is ranged in opposite columns.

The first polyglott bible was that of cardinal Ximenes, printed in 1517, which contains the Hebrew text, the Chaldee paraphrase on the pentateuch, the Greek version of the LXX, and the antient Latin version. After this, there were many others: as the bible of Justiniani, bishop of Nebio, in Hebrew, Chaldee, Greek, Latin, and Arabic; the psalter, by John Potken, in Hebrew, Greek, Ethiopic, and Latin; Plantin's polyglott bible, in Hebrew, Chaldee, Greek, and Latin, with the Syriac version of the New Testament; M. Le Jay's bible in Hebrew, Samaritan, Chaldee, Greek, Syriac, Latin, and Arabic; Walton's polyglott, which is a new edition of Le Jay's polyglott, more correct, extensive, and perfect, with several new Oriental versions, and a large collection of various readings, &c.

POLYGON, in geometry, a figure with many sides, or whose perimeter consists of more than four sides at least: such are the pentagon, hexagon, heptagon, &c.

Every polygon may be divided into as many triangles as it has sides: for if you assume a point, as *a* (Plate Miscel. fig. 191), any where within the polygon, and from thence draw lines to every angle *ab*, *ac*, *ad*, &c. they shall make as many triangles as the figure has sides. Thus, if the polygon has six sides (as in the figure above), the double of that is twelve, from whence take four, and there remain eight: then all the angles *b*, *c*, *d*, *e*, *f*, *g*, of that polygon, taken together, are equal to eight right angles. For the polygon having six sides, is divided into six triangles; and the three angles of each, by 1. 32 Eucl. are equal to two right ones; so that all the angles together make twelve right ones: but each of these triangles has one angle in the point *a*. and by it they complete the space round the same point; and all the angles about a point are known to be equal to four right ones; wherefore those four taken from twelve, leave eight, the sum of the right angles of the hexagon.

So it is plain the figure has twice as many right angles as it has sides, except four. *Q. E. D.*

Every polygon circumscribed about a circle is equal to a rectangled triangle, one of whose legs shall be the radius of the circle, and the other the perimeter (or sum of all the sides) of the polygon. Hence every regular polygon is equal to a rectangled triangle, one of whose legs is the perimeter of the polygon, and the other a perpendicular drawn from the centre to one of the sides of the polygon. And every polygon circumscribed about a circle is bigger than it, and every polygon inserted is less than the circle; as is manifest, because the thing containing is always less than the thing contained.

The perimeter of every polygon circumscribed about a circle is greater than the circumference of that circle, and the perimeter of every polygon inscribed is less. Hence, a circle is equal to a right-angled triangle, whose base is the circumference of the circle, and its height the radius of it.

For this triangle will be less than any polygon circumscribed, and greater than any inscribed; because the circumference of the circle, which is the base of the triangle, is greater than the compass of any inscribed, therefore it will be equal to the circle. For, if this triangle is greater than any thing that is less than the circle, and less than any thing that is greater than the circle, it follows that it must be equal to the circle. This is called the quadrature or squaring of the circle; that is, to find a right-lined figure equal to a circle, upon a supposition that the basis given is equal to the circumference of the circle: but actually to find a right line equal to the circumference of a circle, is not yet discovered geometrically. See CIRCLE.

Problems concerning polygons. 1. On a regular polygon to circumscribe a circle, or to circumscribe a regular polygon upon a circle. Bisect two of the angles of the given polygon A and B (Plate Miscell. fig. 192), by the right lines AF, BF; and on the point F, where they meet, with the radius AF, describe a circle which will circumscribe the polygon. Next to circumscribe a polygon, divide 360 by the number of sides required, to find *c* F *d*; which set off from the centre F, and draw the line *de*, on which construct the polygon as in the following problem. 2. On a given line to describe any given regular polygon. Find the angle of the polygon in the table, and in E set off an angle equal thereto; then drawing EA = ED, through the points E, A, D, describe a circle, and in this applying the given right line as often as you can, the polygon will be described. 3. To find the sum of all the angles in any given regular polygon. Multiply the number of sides by 180°; from the product subtract 360°, and the remainder is the sum required: thus, in a pentagon, 180 × 5 = 900, and 900 — 360 = 540 = the sum of all the angles in a pentagon. 4. To find the area of a regular polygon. Multiply one side of the polygon by half the number of sides; and then multiply this product by a perpendicular let fall from the centre of the circumscribing circle, and the product will be the area required: thus, if AB (the side of a pentagon) = 54 × 2½ = 135, and 135 × 29 (the perpendicular) = 3915 = the area required. 5. To find the area of an irregular polygon, let it be resolved into triangles, and the sum of the areas of these will be the area of the polygon.

The following Table exhibits the most remarkable particulars in all the polygons, up to the dodecagon of 12 sides; viz. the angle at the centre, the angle of the polygon, and the area of the polygon, when each side is 1.

No. of sides.	Name of polygon.	Angle at cent.	Angle of polyg.	Area.
3	Trigon	120°	60°	0.4330127
4	Tetragon	90	90	1.0000000
5	Pentagon	72	108	1.7204774
6	Hexagon	60	120	2.5980762
7	Heptagon	$51\frac{3}{7}$	$128\frac{4}{7}$	3.6339124
8	Octagon	45	135	4.8284271
9	Nonagon	40	140	6.1818242
10	Decagon	36	144	7.6942088
11	Undecagon	$32\frac{8}{11}$	$147\frac{3}{11}$	9.3656399
12	Dodecagon	30	150	11.1961524

POLYGON, in fortification, denotes the figure of a town or other fortress.

The exterior or external polygon is bounded by lines drawn from the point of each bastion to the points of the adjacent bastions. And the interior polygon is formed by lines joining the centres of the bastions.

Line of POLYGONS, on the French sectors, is a line containing the homologous sides of the first nine regular polygons inscribed in the same circle; that is, from an equilateral triangle to a dodecagon.

POLYGONAL NUMBERS, are so called because the units whereof they consist may be disposed in such a manner as to represent several regular polygons.

The side of a polygonal number is the number of terms of the arithmetical progression that compose it; and the number of angles is that which shews how many angles that figure has, whence the polygonal number takes its name.

To find a polygonal number, the side and number of its angles being given, the canon is this: the polygonal number is the semi-difference of the factums of the square of the side into the number of angles diminished by two units, and of the side itself into the number of angles diminished by four units.

The several sorts of polygonal numbers, viz. the triangles, squares, pentagons, hexagons, &c. are formed from the addition of the terms of the arithmetical series, having respectively their common difference 1, 2, 3, 4, &c.; viz. if the common difference of the arithmeticals is 1, the sums of their terms will form the triangles; if 2, the squares; if 3, the pentagons; if 4, the hexagons, &c. Thus:

Arith. Prog.	1,	2,	3,	4,	5,	6,	7.
Trian. Nos.	1,	3,	6,	10,	15,	21,	28.
Arith. Prog.	1,	3,	5,	7,	9,	11,	13.
Square Nos.	1,	4,	9,	16,	25,	36,	49.
Arith. Prog.	1,	4,	7,	10,	13,	16,	19.
Pentag. Nos.	1,	5,	12,	22,	35,	51,	70.
Arith. Prog.	1,	5,	9,	13,	17,	21,	25.
Hexag. Nos.	1,	6,	15,	28,	45,	66,	91.

The sums of polygonal numbers collected in the same manner as the polygonal numbers themselves are, out of arithmetical progressions, are called pyramidal numbers.

POLYGONUM, *knot-grass*, a genus of the trigynia order, in the octandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is quinquepartite and calycine, or serving instead of a calyx; there is one angulated seed. There are 36 species; but the most remarkable are:

1. The bistorta, bistort, or greater snake-weed. 2. The viviparum, or smaller bistort. Both these perennials flower in May and June, succeeded by ripe seeds in August. They grow wild in England, &c.; the first in moist, the other in mountainous situations. 3. Oriental polygonum, commonly called persicaria. 4. Fagopyrum, buck-wheat or brank, rises with an upright, smooth, branchy stem, from about a foot and a half to a yard high, heart-shaped sagittated leaves, and the branches terminated by clusters of whitish flowers, succeeded by large angular seeds, excellent for feeding pigeons and most sorts of poultry.

The root of a kind of bistort, according to Gmelin, is used in Siberia for ordinary food. This species is by Haller called bistorta foliis ad oram nervosis, and by some other botanists bistorta montana minor. The natives call it mouka; and so indolent are they, that, to save themselves the trouble of digging it out of the earth, they go in spring and pillage the holes of the mountain-rats, which they find filled with these roots. In our country, bistort is used as a medicine. All the parts of bistort have a rough austere taste, particularly the root, which is one of the strongest of the vegetable astringents. It is employed in all kinds of immoderate hæmorrhages and other fluxes, both internally and externally, where astringency is the only indication. It is certainly a very powerful styptic, and is to be looked on simply as such; the sudorific, anti-pestilential, and other like virtues ascribed to it, it has no other claim to, than in consequence of its astringency, and of the antiseptic power which it has in common with other vegetable styptics. The largest dose of the root in powder is a single drachm.

POLYGYNIA, among botanists, denotes an order or subdivision of a class of plants; comprehending such plants of that class as have a great number of pistils, or female organs of generation. See BOTANY.

POLYHEDRON, in geometry, denotes a body or solid comprehended under many sides or planes. A gnomic polyhedron is a stone with several faces, whereon are described various kinds of dials.

POLYHEDRON, *polyscope*, in optics, is a multiplying-glass or lens, consisting of several plane surfaces disposed into a convex form. See OPTICS.

POLYMNIA, a genus of the polygamia necessaria order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; there is no pappus; the exterior calyx is tetraphyllous, or pentaplyllous; the interior decaphyllous, and composed of concave leaflets. There are five species.

POLYNEMUS, *polyneme*, a genus of fishes of the order abdominales. The generic character is, head compressed, covered with scales; snout very obtuse and prominent; gill-membrane five or seven-rayed; separate filaments or setaceous processes near the base of the pectoral fins.

1. Polynemus paradiseus. The genus polynemus may be considered as holding the same station among the abdominal fishes which the genus trigla does among the thoracic; being distinguished by a similar circumstance, viz. that of being furnished on each side, near the base of the pectoral fins, with several separate processes or articulated rays: these are, in general, much longer and more setaceous than in the triglæ, and, in some species, even exceed the length of the whole body. The species of polyneme are not very numerous, and are chiefly confined to the warmer latitudes.

The polynemus paradiseus, or mango-fish, as it is generally called, which seems to have been one of the first of the genus known to the Europeans, is an inhabitant of the Indian and American seas, and grows to the length of about 12 or 15 inches. It is a fish of an elegant shape, moderately broad in the middle, and gradually tapering towards the tail, which is very deeply forked; the scales are of moderate size, those towards the head and tail smaller than the rest; the thoracic filaments are of excessive length, the superior or outward ones often extending far beyond the tail; the others gradually shorten, the first or lowermost extending about half the length of the body. The colour of this fish is generally described as yellow, and its popular name of mango-fish is supposed to have been given it from that circumstance, as resembling the colour of a ripe mango. Dr. Russel, in his work on the Indian fishes, informs us, that the mango-fish is reckoned by much the most delicate of any found at Calcutta.

2. Polynemus plebeius. General appearance that of a mullet, but with the head very obtuse in front, the mouth appearing as if placed beneath; colour silvery grey, with a dusky tinge on the upper parts, and several dusky lines running from head to tail above the lateral line; scales rather large; all the fins scaly to some distance from the base; tail forked; thoracic filaments five in number on each side; the first of these is said by Gmelin to exceed the length of the body, the rest decreasing gradually.

This species is a native of the Indian and American seas, and is found about the coasts of several of the southern islands. It arrives at a very large size, measuring upwards of four feet in length. It is considered as an excellent fish for the table, and is in much esteem among the inhabitants of the Malabar coast. It is dressed in various ways, and is sometimes dried and salted for sale. Dr. Bloch informs us, on the authority of a correspondent on whom he could rely, that this fish is commonly known in India by the title of royal fish, on account of its excellence, and laments that Broussonet (who seems to have named it from its want of particular splendour) should have given it the title of P. plebeius.

3. Polynemus niloticus. This, according to Mr. Bruce, who describes and figures it in the Appendix to his Travels, is a large species, and may vie, for the elegance both of its form and taste, with any fish inhabiting the rivers running either into the Mediterranean or the ocean. The specimen from which Mr. Bruce's figure was taken weighed 32 pounds, but is said often to arrive at the weight of 70 or more. It is an inhabitant of the river Nile, where it is by no means uncommon as far up the river as Syene and the first cataract. The whole body is covered with scales of a brilliant silver-colour, so as to resemble spangles lying close together; and there is no variety of tinge on the fish, except a shade of red on the end of the nose, which is fat and fleshy.

We are informed by Mr. Bruce, that in order to take this fish, the Egyptian peasants prepare a pretty large mass or cake, consisting of oil, clay, flour, honey, and straw, kneading it with their feet till it is well incorporated. They then take two handfuls of dates and break them into pieces about the size of the point of a finger, and stick them in different parts of the mass; into the heart of which they put seven or eight hooks with dates upon them, and a string of strong whipcord to each. This mass of paste is then conveyed by the fisherman or shepherd into the stream, the man sitting for this purpose on a blown up goat-skin. When arrived at the middle, he drops the mass in the deepest part of the stream; and cautiously holding the ends of each of the strings slack, so as not to pull the dates and hooks out of the middle of the composition, he makes to shore again, a little below the spot where he has sunk the mass; and separating the ends of the strings, ties each of them, without straining, to a palm-branch fastened on the shore, to the end of which is fastened a small bell.

He then goes and feeds his cattle, or digs his trenches, or lies down to sleep. In the mean time the cake beginning to dissolve, the small pieces of date fall off, and flowing down the stream, are eagerly seized on by the fishes as they pass: they rush up the stream, picking up the floating pieces as they go, till at length they arrive at the cake itself, and voraciously falling to work at the dates which are buried in it, each fish, in swallowing a date, swallows also the hook in it, and feeling himself fast, makes off as speedily as possible: the consequence is, that in endeavouring to escape from the line by which he is held, he pulls the palm-branch to which it is fastened, and thus gives notice of his capture by ringing the bell. The fisherman runs, and having secured the fish, puts a strong iron ring through his jaw, ties a few yards of cord to it, and again commits him to the water, fastening the cord well to the shore. This is practised in order to preserve the fish ready for sale, since fish in general, when dead, will not keep long in these regions. It is rarely that on these occasions a single hook is found empty. The inhabitants of the towns of Achmim, Girge, and others, repair at intervals to the shores as to a fish-market, and are thus supplied by the country-people. There are other species.

POLYPODIUM, in botany, a genus of the order of filices, in the cryptogamia class of plants. The fructifications are in roundish points, scattered over the inferior disc of the frons or leaf. There are 137 species, of which the most remarkable is the filix mas, or common male fern. This grows in great plenty throughout Britain, in woods and stony uncultivated soils. The greatest part of the root lies horizontally, and has a great number of appendages placed close to each other in a vertical direction, while a number of small fibres strike downwards. The stalks are covered with brown filmy scales. The fructifications are kidney-shaped, and covered with a permanent scaly shield or involucrum. The capsules are of a pale brown, surrounded with a saffron-coloured elastic ring.

This fern has nearly the same qualities, and is used for most of the same intentions, as the pteris aquilina. They are both burnt together for the sake of their ashes, which are purchased by the soap and glass-makers. In the island of Jura are exported annually 150*l*.-worth of these ashes. Gunner relates, in his Flor. Noveg. that the young curled leaves, at their first appearance out of the ground, are by some boiled and eaten like asparagus; and that the poorer Norwegians cut off those succulent laminæ, like the nails of the finger at the crown of the root, which are the bases of the future stalks, and brew them into beer, adding a third portion of malt, and in times of great scarcity mix the same in their bread. The same author adds, that this fern cut green, and dried in the open air, affords not only an excellent litter for cattle, but, if infused in hot water, becomes no contemptible fodder to goats, sheep, and other cattle, which will readily eat and sometimes grow fat upon it. But the anthelmintic quality of the root of the male fern is that for which it is chiefly to be valued, and of which an account is given in the French publications of madame Nouffer, who employed this remedy with great success. Dr. Simmons also has described the mode of administering the fern-root in his treatise on the tape-worm.

POLYPREMUM, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 22d order, caryophyllei. The calyx is tetraphyllous; the corolla quadrifid and rotaceous, with its lobes obcordate; the capsule is compressed, emarginated, and bilocular. There is one species, an annual of Cusolim.

POLYPUS, the popular name for those fresh-water insects, which class under the genus of hydra, of the order of vermes zoophytæ. The name of hydra was given them by Linnæus on account of the property they have of reproducing themselves when cut in pieces, every part soon becoming a perfect animal. Dr. Hill called them biota, on account of the strong principle of life with which every part of them is endowed. See Hydra.

Polypus, or Polypus of the heart. See Medicine.

Polypus *of the nose*. See Surgery.

POLYPASTON, in mechanics, a machine consisting of an assemblage of several pulleys; for the nature and force of which, see Mechanics.

POLYSPERMOUS. See Botany.

POLYTRICHUM, a genus of the order of musci, in the cryptogamia class of plants. The anthera is operculated, and placed upon a very small apophysis or articulation; the calyptra villous; the star of the female is on a distinct individual. There are 19 species; the most remarkable of which is the commune, or great golden maiden-hair, frequently to be met with in the bogs and wet places of this country. It grows in patches, the stalks erect, generally single and unbranched, from three inches to a foot, or even a yard, high. It is sometimes used in England and Holland to make brooms or brushes; and the Laplanders, when obliged to sleep in desert places, frequently make of it a speedy and convenient bed. Their manner of doing it is curious: Where this moss grows thick together, they mark out with a knife a piece of ground, about two yards square, or of the size of a common blanket; then beginning at one corner, they gently sever the turf from the ground; and as the roots of the moss are closely interwoven and matted together, they by degrees strip off the whole circumscribed turf in one entire piece; afterwards they mark and draw up another piece, exactly corresponding with the first; then, shaking them both with their hands, they lay one upon the ground, with the moss uppermost, instead of a mattress, and the other over it, with the moss downwards, instead of a rug; and between them both take a comfortable nap, free from fleas and bugs, and without fear of contagious distempers. It is probable they might take the hint of making such a bed from the bear, a cohabitant of their country, which prepares his winter-quarters with a large collection of this moss.

POMETIA, a genus of the monœcia hexandria class and order. The calyx is one-leaved, six-cleft; petals six; male stamina six; female, berry globular, one seed in the centre. There are two species.

POMMEREULIA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the fourth order, gramina. The calyx is bivalved, and shaped like a top; the valvula quadrifid, and bearded on the back. The corolla has two unequal valves; the filaments three, with long pointed antheræ; the style simple. The whole flower forms itself into a sharp point, and the corolla serves as a covering to the seed, which is long, clear, and smooth. There is only one species, a grass of the East Indies.

PONŒA, a genus of the octandria trigynia class and order. The calyx is five-parted, spreading; petals four; germ. three-sided; capsules three-winged, three-celled. There is one species, a tree of Guiana.

PONTEDERIA, in botany, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is monopetalous, sexfid, bilabiate; there are three stamina inserted into the top, and three into the tube of the corolla; the capsule is bilocular. There are seven species, aquatics of the East Indies.

PONTON, or Pontoon, in war, denotes a little floating bridge made of boats and planks. The ponton is a machine consisting of two vessels, at a little distance, joined by beams, with planks laid across for the passage of the cavalry, the cannon, infantry, &c. over a river, or an arm of the sea, &c. The late-invented ponton is of copper, furnished with an anchor, &c. to fix to it. To make a bridge, several of these are disposed two yards asunder, with beams across them; and over those are put boards or planks. They are also linked to each other, and fastened on each side the river by a rope run through a ring in each of their heads, and fixed to a tree or stake on either shore; the whole makes one firm uniform bridge, over which a train of artillery may pass.

POOP, the stern of a ship, or the highest, uppermost, and hinder part of the ship's hull.

POOR, in law. Where the last legal settlement of the father of a legitimate child is not known, the child may be sent to the place of its birth, as well as an illegitimate one. Blackerby, 246.

A legitimate child shall necessarily follow the settlement of its parents as a nurse-child or as part of the family, only till it is seven years of age; and after that age, it shall not be removed as part of the father's family; but with an adjudication of the place of its own legal settlement, as being deemed capable at that age of having gained a settlement of his own.

If a person is bound apprentice by indenture, wherever he continues forty days in the service of his master or mistress, there such apprentice gains a settlement; and where any person serves the last forty days of his apprenticeship, that is the place of his last legal settlement.

The 8 and 9 W. 3. c. 30 explains, that as some doubts had arisen touching the settlement of unmarried persons, not having child or children, lawfully hired into any parish or town for one year, it was enacted, that no such person so hired as aforesaid, should be deemed to have a good settlement in any such parish or township, unless such person should continue and abide in such service during the space of one whole year.

A general hiring, without any particular time agreed upon, is construed to be a hiring for a year, and therefore sufficient.

It is not the terms of the hiring, but the intention, that is the criterion; for though a servant may be hired for so much per week, yet if it is understood at the time, that he is to continue for the year if approved of, it is equal to a hiring for a year.

A woman marrying a husband who has a known settlement, shall follow her husband's settlement.

The act of 9 and 10 W. c. 11. does not require a person renting a tenement of 10*l.* a year, to occupy it; it is enough if he rents it and resides forty days in the parish.

POOR'S-RATE, a tax levied in England and Wales, for the relief or support of such persons as from age, infirmity, or poverty, cannot themselves procure the means of subsistence. The first law made in England respecting paupers was in 1496; it directs, "that every beggar, not able to work, shall resort to the hundred where he last dwelt, is best known, or was born; and shall there remain, upon pain of being set in the stocks three days and three nights, with only bread and water, and then shall be put out of town." The monasteries and nunneries with which the country then abounded, were the principal sources from which the poor obtained relief. In 1531 an act was passed, by which the justices of every county were empowered to grant licences to poor, aged, and impotent persons, to beg within a certain precinct; and such as should beg without licence or beyond their limits, were to be severely punished. This regulation was soon found ineffectual; and in 1536, the officers of counties, towns, and parishes, were directed to provide for the support of all aged, poor, and impotent persons, who had resided three years in one place, by means of voluntary contributions to be raised for this purpose in every parish. In 1547 and in 1555, acts were passed for the providing for the poor, by means of weekly collections from the charitably disposed inhabitants of each parish; but this provision was found to be very insufficient, particularly as the number of beggars had increased considerably upon the suppression of the monasteries, from whence many of them derived their principal support. It was therefore found necessary in 1563, to go a step further, by providing, that if any parishioner shall refuse to contribute voluntarily towards the relief of the poor; "the justices of the peace at their quarter-sessions, may tax him to a reasonable weekly sum, which if he refuses to pay, they may commit him to prison." This may be considered as the commencement of the poor's rate, which was rendered more general in 1572, by an act directing, that assessments should be made of the parishioners of every parish, for the relief of the poor. In 1601, nearly the present mode of collecting this rate was established; the churchwardens and overseers of the poor of every parish, or the greater part of them (with the consent of two justices) being empowered to raise weekly, or otherwise, by taxation of every inhabitant, parson, vicar, and other, and of every occupier of lands or houses, materials for employing the poor, and competent sums for their relief. Notice to be given in church of every such rate, the next Sunday after it is allowed. The rate to be levied by distress, on those who refuse to pay it; but appeals against it may be made by those who think themselves aggrieved.

In 1735, a committee of the house of commons was appointed, to consider the existing laws relative to the maintenance and settlement of the poor: who recommended the establishment of workhouses, hospitals, and houses of correction, to be under the management of proper persons, who should be one body politic; and that the laws relating to the poor should be reduced into one act of parliament.

Return made to parliament of the money raised for maintenance of the poor, from Easter 1775 to Easter 1776.

Money raised in England	£ 1,678,915	14	4
Ditto - Wales	40,114	1	0
	£ 1,719,029	15	4

In 1804, a more particular account was obtained, in consequence of an act passed "for procuring returns relative to the expence and maintenance of the poor in England;" from which it appeared, that the number of persons receiving relief from the poor's-rate, was as follows:

1. Persons relieved permanently:	
Out of any house of industry, workhouse, &c. -	336,199
In any house of industry, workhouse, &c. -	83,468
2. Children of persons relieved permanently out of the house, and other children maintained out of the house:	
Under 5 years of age -	120,236
From 5 to 14 years of age	194,914
3. Persons relieved occasionally:	305,899
	1,040,716

This number, great as it appears, is exclusive of 194,052 persons who were not parishioners, the greater part of whom are supposed to have been vagrants.

The total sum raised by the poor's-rate and other parish rates in England and Wales, in the year ending Easter, 1803, was, 5,348,205*l* 9*s.* 3¾*d.*; of which 4,267,965*l.* 9*s.* 2*d.* was expended on account of the poor.

The average rate in the pound of the poor's-rate for the year 1803, was in all England 4*s.* 4½*d*, in Wales, 7*s.* 1½*d.*

POPE, PAPA, FATHER, the sovereign pontiff, or supreme head of the Romish church. The appellation of pope was antiently given to all christian bishops; but about the latter end of the eleventh century, in the pontificate of Gregory VII. it was usurped by the bishop of Rome, whose peculiar title it has ever since continued. The spiritual monarchy of Rome sprung up soon after the declension of the Roman empire. This sovereign is addressed under the term holiness, and in the council of the Lateran held under Innocent III. he was declared ordinary of ordinaries. The pope was an absolute monarch in his Italian dominions, and his power was very considerable; being able, in case of necessity, to put fifty thousand men into the field, besides his naval strength in galleys. The French revolution, which has reversed all order, and overthrown every government where its power extended, and substituted a barbarous and military tyranny in its place, has greatly impaired the splendour, dignity, and power of the pope; nor shall we be at all surprised to see the papal throne entirely reversed, and the territories added to some of the subordinate kingdoms lately erected by the usurper of France.

POPLITÆUS. See ANATOMY.

POPLITEA. See ANATOMY.

POPPY. See PAPAVER.

POPULATION, the state of a country with respect to the number of inhabitants. The greater number of persons any country contains, the greater are the means it possesses of carrying agriculture, manufactures, and commerce, to a great extent, and likewise of defending itself against any hostile attempts of other states; a high degree of population has therefore been generally considered as conducive to national prosperity and security; and almost all writers on political economy, have assumed an increasing population as one of the principal objects which the internal regulations of a country should be calculated to promote. A very different view of the subject has been lately given by Mr. Malthus, who, adopting as a principle, "the constant tendency in all animated life to increase beyond the nourishment prepared for it," traces to this source a very considerable portion of the vice and misery, and of that unequal distribution of the bounties of nature, which it has been the unceasing object of the enlightened philanthropist in all ages to correct. The subject will perhaps be seen in a clearer light, if we endeavour to ascertain, what would be the natural increase of population, if left to exert itself with perfect freedom; and what might be expected to be the rate of increase in the productions of the earth, under the most favourable circumstances of human industry. It will be allowed, that no country has hitherto been known, where the manners were so pure and simple, and the means of subsistence so abundant, that no check whatever has existed to early marriages, from the difficulty of providing for a family; and no waste of the human species has been occasioned afterwards by vicious customs, by towns, by unhealthy occupations, or too severe labour; consequently in no state that we have yet known, has the power of population been left to exert itself with perfect freedom. In the northern states of America, where the means of subsistence have been more ample, the manners of the people more pure, and the checks to early marriages fewer, than in any of the modern states of Europe, the population was found to double itself for some successive periods, every twenty-five years. In the back settlements, this effect took place in fifteen years. Sir W. Petty supposed a doubling possible in so short a time as ten years; but to be sure of being within the truth, Mr. Malthus takes the slowest of these rates of increase, and thus assumes that population, when unchecked, goes on doubling itself every twenty-five years, or increases in a geometrical ratio. The rate according to which the productions of the earth may be supposed to increase, is not so easily determined; but it is certain, that when acre has been added to acre, till all the fertile land is occupied, the yearly increase of food must depend upon the amelioration of the land already in cultivation; this is a stream which, from the nature of all soils, instead of increasing, must be gradually diminishing; but population, could it be supplied with food, would go on with unexhausted vigour, and the increase of one period would furnish the power of a greater increase the next, and this without any limit. In order to illustrate this point, let it be supposed that by the best possible policy, and great encouragements to agriculture, the annual produce of Great Britain could be doubled in the first twenty-five years; in the next twenty-five years, it is impossible to suppose, that the produce could be quadrupled; it would be contrary to all knowledge of the properties of land. Let it then be supposed, that the yearly additions which might be made to the former average produce, instead of decreasing, which they certainly would do, were to remain the same; and that the produce of Great Britain might be increased every twenty-five years, by a quantity equal to what it at present produces. The most enthusiastic speculator cannot suppose a greater increase than this; in a few centuries it would make every acre of land in the island like a garden. If this supposition is applied to the whole earth, it will appear that the means of subsistence, under circumstances the most favourable to human industry, could not possibly be made to increase faster than in an arithmetical ratio.

Mr. Malthus shews the necessary effects of these two different rates of increase, and observes, that taking the whole earth, by which means emigration is excluded, and supposing the present population equal to a thousand millions, the human species would increase as the numbers 1, 2, 4, 8, 16, 32, 64, 128, 256, and subsistence as 1, 2, 3, 4, 5, 6, 7, 8, 9. In two centuries, the population would be to the means of subsistence as 256 to 9; in three centuries, as 4096 to 13; and in two thousand years the difference would be almost incalculable. In this supposition, no limits whatever are placed to the produce of the earth. It may increase for ever, and be greater than any assignable quantity; yet still the power of population being in every period so much superior, the increase of the human species can only be kept down to the level of the means of subsistence, by the constant operation of the strong law of necessity, acting as a check upon the greater power.

From these principles, Mr. Malthus deduces the following propositions: 1. Population is necessarily limited by the means of subsistence. 2. Population invariably increases, where the means of subsistence increase, unless prevented by some very powerful and obvious checks. 3. The checks which repress the superior power of population, and keep its effects on a level with the means of subsistence, are all resolvable into moral restraint, vice, and misery.

Moral restraint, or the determination to defer or decline matrimony from a consideration of the inconveniences or deprivations to which a large portion of the community would subject themselves by pursuing the dictate of nature, Mr. Malthus denominates the preventive check; and whatever contributes to shorten the natural duration of human life (as all unwholesome occupations, severe labour, and exposure to the seasons; extreme poverty, bad nursing of children, great towns, excesses of all kinds, the whole train of common diseases and epidemics, wars, pestilence, plague, and famine) are the positive checks to population. From a review of the former and present state of society in different countries, it appears, that in modern Europe, the positive checks to population prevail less, and the preventive check more, than in past time, and in the more uncivilized parts of the world.

In the actual state of every society, the natural progress of population has thus been constantly and powerfully restrained; and as no form of government, however excellent, no plans of emigration, no benevolent institutions, no degree or direction of national industry, can prevent the action of a great check to increase in some form or other; as we must submit to it as an inevitable law of nature; it becomes highly desirable to ascertain how it may take place with the least possible prejudice to the virtue and happiness of human society. Now, as it is clearly better that the check to population should arise from a foresight of the difficulty of rearing a family, and the fear of dependant poverty, than from the actual presence of pain and sickness; moral restraint is a virtue, the practice of which is most earnestly to be encouraged. If no man was to marry, who had not a fair prospect of providing for the presumptive issue of his marriage, population would be kept within bounds by the preventive check; men and women would marry later in life, but in the full hope of their reward; they would acquire habits of industry and frugality, and inculcate the same in the minds of their children. Mr. Malthus does not go so far as to propose, that any restraint upon marriage between two persons of proper age should be enforced by law, but insists, that the contract of marriages between persons who have no other prospect of providing for their offspring than by throwing them on a parish, should not be, as it is at present, encouraged by law. One of the effects of the poor-laws, is to encourage marriage between persons of this description; who well know that, if they cannot provide for their own children, the parish must take them off their hands. These laws thus create mouths, but are perfectly incompetent to procure food for them: instead of raising the real price of labour, by increasing the demand for labourers, they tend to overstock the market, to reduce the demand, and diminish the value. They raise the price of provisions by increasing the consumption, and by supplying the parochial pensioners with the means of obtaining them. In consequence of this, the class of industrious labourers who are above soliciting assistance, are oftentimes sunk in the scale of misery, much lower than others who have thrown off all sense of shame, and all the honest feelings of independance. In a moral point of view, the effects of these laws are equally injurious to the best interests of society. Mr. Malthus, however, is aware, that the immediate and abrupt abolition of the present system, would produce much temporary distress; he suggests therefore a plan for the gradual abolition of these laws, by proposing, that no child born from any marriage taking place after the expiration of a year from the date of the law, and no illegitimate child born two years from the same date, should be entitled to parish-assistance. This, he remarks, would operate as a fair, distinct, and precise notice, which no man could mistake; and without pressing hard upon any particular individual, would at once throw off the rising generation from that miserable and helpless dependance upon the government and the rich, the moral as well as the physical consequences of which, are almost incalculable.

The progress of the population of the world, and its present total amount, cannot be ascertained with much precision; as there are no sufficient grounds on which such a computation can be formed, till within a very late period, and that only in a few countries. Sir W. Petty, in 1682, stated the population of the world at only 320 millions: it has been estimated by some writers at about 730 millions, by others at upwards of 900 millions. Mr. Wallace, of Edinburgh, conjectured it might amount to 1000 millions; and this number has since been generally adopted by those who have noticed the subject. It is a point on which accuracy cannot be expected, but a nearer approximation to the truth appears by no means impracticable. A strong presumption that the inhabitants of the earth at present exceed considerably a thousand millions, arises from the circumstance, that, in almost every country where the people have been numbered, or sufficient data furnished for computing their number, it has been found considerably greater than it had been previously supposed. In Great Britain, the most correct estimates did not make the population exceed seven or eight millions; whereas, by the late enumeration, it appears to amount to very near eleven millions. France, the population of which was estimated by Mr. Susmilch at sixteen millions, by M. Deslandes and by Mr. Gibbon at 20 millions, and which M. Messance endeavoured to prove amounted to near 24 millions, appeared from the returns of births and burials, to contain at the commencement of the revolution near 30 millions of inhabitants. Spain, which with Portugal had been estimated by M. Deslandes to contain only six millions of persons, and by Mr. Gibbon eight millions, was found by the enumeration in 1787, to contain alone 10,409,879. Russia, about the year 1765, was supposed to contain about 15 millions of inhabitants; but according to the calculation given by Mr. Coxe, grounded upon an authentic list of the persons paying the poll-tax, they amounted to 26,766,360, and including the provinces not subject to the poll-tax, the calculation for the year 1796 amounted to 36,000,000 inhabitants. A great part of this vast empire is in Asia; but there appears from these and similar accounts great reason to conclude, that the population of Europe, which has usually been supposed to be about 100 millions, is considerably greater; and the following statement is probably not far from the truth:

Spain -	10,500,000
Portugal - -	2,300,000
France - -	25,000,000
Italy and its islands -	11,000,000
Switzerland - -	1,800,000
Germany - -	20,000,000
Holland - - -	2,800,000
Flanders - -	1,800,000
Great Britain and Ireland	15,100,000

Denmark and Norway	-	3,700,000
Sweden	-	3,000,000
Prussia	-	6,000 000
Russia in Europe	-	20,000,000
Turkey in Europe	-	7,000,000
	Total	130,000,000.

The act for ascertaining the population of Great Britain, was passed on the last day of the year 1800; it directed a general enumeration of houses, families, and persons; and the proper officers of the several parishes and places were ordered to take the account, on the 10th of March, 1801, in England and Wales; and in Scotland as soon as possible after that day. This difference was necessary, because in the colder climate of Scotland, it was not certain that all parts of the country would be easily accessible so early in the year. An abstract of the returns was laid before both houses of parliament; and the summary of the enumeration appeared to be as follows:

	HOUSES. Inhabited.	HOUSES. By how many families occupied.	HOUSES. Uninhabited.	PERSONS. Males.	PERSONS. Females.	PERSONS. Total.
England - - -	1,472,873	1,787,520	53,965	3,987,935	4,343,499	8,331,434
Wales - - -	108,053	118,303	5,511	257,178	284,368	541,546
Scotland - - -	294,553	364,379	9,537	734,581	864,487	1,599,068
Army, including Militia - -	—	—	—	198,351	—	198,351
Navy, including Marines - -	—	—	—	126,279	—	126,279
Seamen in registered shipping	—	—	—	144,558	—	144,558
Convicts on board the hulks -	—	—	—	1,410	—	1,410
Total - - -	1875,456	2,269,902	67,013	5,450,292	5,492,354	10,942,646

The total population of Great Britain probably exceeds the number of persons specified in the above summary, as there were some parishes from which no returns were received. The islands of Guernsey, Jersey, Alderney, and Sark, the Scilly islands, and the isle of Man, were not comprised in the enumeration; the total population of these islands has been usually estimated at about 80,000 persons.

The number of houses in Ireland has been nearly ascertained by the collection of a hearth-money tax, from which it has been computed, that the population of that part of the United Kingdom somewhat exceeds four millions of persons.

On these considerations, with a very moderate allowance for omissions in the returns, the total population of the united kingdom of Great Britain and Ireland, amounts to 15,100,000 persons; and, besides these, its eastern and western possessions and colonies contain many natives of the British isles.

The proportion of persons to a house appeared by the returns to be as follows:

In England	- - -	$5\frac{2}{3}$
Wales	- - -	5
Scotland	- - -	$5\frac{2}{7}$
Great Britain	- -	$5\frac{5}{9}$

Population of the principal Sea Ports and Manufacturing Towns of Great Britain, and of France.

GREAT BRITAIN.	Inhabitants.	FRANCE.	Inhabitants.
London - -	864,845	Paris - - -	546,856
Manchester -	84,020	Bourdeaux	112 844
Edinburgh -	82,560	Lyons - - -	109,500
Liverpool -	77,653	Marseilles	111,130
Glasgow - -	77,385	Rouen - -	87,000
Birmingham -	73,670	Nantes - -	73,649
Bristol - -	63,645	Brussels - -	66,227
Leeds - - -	53,162	Lisle - - -	54,756
Plymouth -	43,194	Toulouse - -	50,171
Norwich - -	36,832	Strasburg	49,056
Portsmouth -	32,166	Cologne - -	38,844
Sheffield - -	31,314	Bruges - -	33,760
Hull - - -	29,516	Dunkirk - -	21,158
Nottingham -	28,861	Brest - -	27,000
Newcastle -	28,366	Toulon - -	20,500

POPULUS, the POPLAR, a genus of the octandria order, in the diœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. The calyx of the amentum is a lacerated, oblong, and squamous leaf; the corolla is turbinated, oblique, and entire. The female has the calyx of the amentum and corolla the same as in the male; the stigma is quadrifid; the capsule bilocular, with many pappous seeds. There are eleven species; the most noted are:

1. The alba, or abele-tree, grows naturally in the temperate parts of Europe. Its leaves are large, and divided into three, four, or five lobes, indented on their edges, of a very dark colour on their upper side, but very white and downy on the under side; standing upon footstalks an inch long. The young branches have a purple bark, and are covered with a white down; but the bark of the stem and older branches is grey. 2. The major, or white poplar, has its leaves rounder than the first, and not much above half their size; they are indented on their edges, and are downy on their under side, but not so white as those of the former, nor are their upper surfaces of such a deep green colour. 3. The nigra, or black poplar, has oval heart-shaped leaves, slightly crenated on their edges; they are smooth on both sides, and of a light-green colour. 4. The tremula, or aspen-tree, has roundish, angularly indented leaves: they are smooth on both sides, and stand on long footstalks, and so are shaken by the least wind; whence it has the title of the trembling poplar, or aspen-tree. 5. The balsamifera, or Carolina poplar, is a native of Carolina, where it becomes a large tree. The shoots of this sort grow very strong in Britain, and are generally angular; with a light green bark like the willow. The leaves on young trees, and also those on the lower shoots, are very large, almost heart-shaped, and crenated; but those upon the older trees are smaller: as the trees advance, their bark becomes lighter, approaching to a greyish colour. 6. The tacamahaca grows naturally in Canada and other parts of North America. This is a tree of a middling growth, sending out on every side many short thick shoots, which are covered with a light-brown bark, with leaves differing from one another in shape and size; most of them are almost heart-shaped, but some are oval, and others nearly spear-shaped; they are whitish on their under side, but green on the upper. 7. The Lombardy poplar (deletata), well known.

These trees may be propagated either by layers or cuttings, as also from the suckers which the white poplars send up from their roots in great plenty. The best time for transplanting these suckers is in October, when their leaves begin to decay.

The wood of these trees, especially of the abele, is good for laying flowers, where it will last for many years, and, on account of its extreme whiteness, is by many preferred to oak; yet, on account of its soft contexture, being very subject to take the impression of nails, &c. it is less proper on this account than the harder woods. The abele likewise deserves particular notice, on account of the virtue of its bark in curing intermitting fevers, as stated by the reverend Mr. Stone, in Phil. Trans. vol. liii. p. 195. This bark will also tan leather.

The inner bark of the black poplar is used by the inhabitants of Kamtschatka as a material for bread; and paper has sometimes been made of the cottony down of the seeds. The roots have been observed to dissolve into a kind of gelatinous substance, and to be coated over with a tubular crustaceous spar, called by naturalists osteocolla, formerly imagined to have some virtue in producing the callus of a fractured bone. The buds of the sixth species are covered with a glutinous resin, which smells very strong, and is the gum tacamahaca of the shops. The best, called (from its being collected in a kind of gourd-shells) tacamahaca in shells, is somewhat unctuous and softish, of a pale yellowish or greenish colour, an aromatic taste, and a fragrant delightful smell, approaching to that of lavender or ambergris. This sort is very rare; that commonly found in the shops is in semitransparent globes or grains, of a whitish, yellowish, brownish, or greenish colour, of a less grateful smell than the foregoing. This resin is said to be employed externally by the Indians for discussing and maturating tumours, and abating pains in the limbs. It is an ingredient in some anodyne, hysteric, cephalic, and stomachic plasters; but the fragrance of the finer sort sufficiently points out its utility in other respects.

M. Fougeroux de Bondaroy, from a set of experiments on the subject, gives an account of the uses of the several kinds of poplar, the substance of which is as follows: He finds that the wood of the black poplar is good and useful for many purposes; that the Lombardy poplar, is of very little value; that the Virginia poplar, populus Virginiana, affords a wood of excellent quality, that may be applied to many uses. The Carolina poplar, populus Carolinensis heterophylla (Lin.), is a very quick grower; beautiful when sound, but liable to be hurt by cold. Its wood appears to M. de Bondaroy to be of little value; but M. Malesherbes, who cu down a large tree of this sort, was assured by his carpenter that the wood was very good. That the tacamahaca is a dwarfish plant of little value. That the liard, populus Canadensis, is a large tree, the wood light, not easy to be split, and fit for several uses. That the white poplar, is a large-growing tree, affording a wood of excellent quality, and is among the most valuable of this species. That the trembling poplar is neither so large a tree, nor affords such good wood, as the former. These are in few words the principal results of the experiments of this gentleman on this class of plants. A few other sorts are mentioned, but nothing decisive with regard to them is determined.

From some experiments made by M. Dambourney, it appears that the poplar may be usefully employed in dyeing. The Italian or Lombardy poplar gives a dye of as fine a lustre, and equally durable, as that of the finest yellow wood, and its colour is more easily extracted. It is likewise very apt to unite with other colours in composition. Besides this, M. Dambourney tried also the black poplar, the Virginian, the balsam or liard, the white, and the trembling poplar; and found that all these dyed wool of a nut-colour, fawn-colour (vigogne), Nankin, musk, and other grave shades, according to the quantity of wood employed, and the length of time it was boiled.

PORANA, a genus of the monogynia order, in the pentandria class of plants. The corolla is campanulated; the calyx is quinquefid, and larger than the fruit; the style semibifid, long, and permanent; the stigmata globular; the perianthium bivalved. There is one species, a shrub of the East Indies.

PORCELAIN, a fine kind of earthenware, chiefly manufactured in China, and thence called China-ware. All earthenwares which are white and semitransparent are generally called porcelain; but amongst these so great differences may be observed, that, notwithstanding the similarity of their external appearance, they cannot be considered as matters of the same kind. These differences are so evident, that even persons who are not connoisseurs in this way prefer much the porcelain of some countries to that of others.

The word porcelain is of European derivation; none of the syllables which compose it can even be pronounced or written by the Chinese, whose language comprehends no such sounds. It is probable that we are indebted to the Portuguese for it; the word porcellana, however, in their language, signifies properly a cup or dish; and they themselves distinguish all works of porcelain by the general name of loca. Porcelain is called in China tsé-ki.

The art of making porcelain is one of those in which Europe has been excelled by the Oriental nations. The first porcelain that was seen in Europe was brought from Japan and China. The whiteness, transparency, fineness, neatness, and even magnificence of this pottery, which soon became the ornament of sumptuous tables, did not fail to excite the admiration and industry of Europeans; and their attempts have succeeded so well, that in different parts of Europe earthenwares have been made so like the Oriental, that they have acquired the name of porcelain. The first European porcelains were made in Saxony and in France; and afterwards in England, Germany, and Italy; but as all these were different from the Japanese, so each of them had its peculiar character.

The finest and best porcelain of China is made in a village called King-te-tching, in the province of Kiang-si. This celebrated village is a league and a half in length, and we are assured that it contains a million of inhabitants. The workmen of King-te-tching, invited by the attracting allurements of the European trade, have established manufactories also in the provinces of Fo-kien and Canton; but this porcelain is not esteemed.

We are indebted to father d'Entrecolles, a Romish missionary, for a very accurate account of the manner in which porcelain is made in China; and as he lived in King-te-tching, his information must have been the very best possible. We shall therefore give his account of the Chinese manner of making it, as abridged by Grosier in his General Description of China. The principal ingredients of the fine porcelain are pe-tun-tse and kao-lin, two kinds of earth, from the mixture of which the paste is produced. The kao-lin is intermixed with small shining particles; the other is purely white, and very fine to the touch. These first materials are carried to the manufactories in the shape of bricks. The pe-tun-tse, which is so fine, is nothing else but fragments of rock taken from certain quarries, and reduced to powder. Every kind of stone is not fit for this purpose. The colour of that which is good, say the Chinese, ought to incline a little towards green. A large iron club is used for breaking these pieces of rock: they are afterwards put into mortars; and, by means of levers headed with stone bound round with iron, they are reduced to a very fine powder. These levers are put in action either by the labour of men, or by water, in the same manner as the hammers of our paper-mills. The dust afterwards collected is thrown into a large vessel full of water, which is strongly stirred with an iron shovel. When it has been left to settle for some time, a kind of cream rises on the top, about four inches in thickness, which is skimmed off, and poured into another vessel filled with water; the water in the first vessel is stirred several times; and the cream which arises is still collected, until nothing remains but the coarse dregs, which, by their own weight, precipitate to the bottom; these dregs are carefully collected, and pounded anew.

With regard to what is taken from the first vessel, it is suffered to remain in the second until it is formed into a kind of crust at the bottom. When the water above it seems quite clear, it is poured off by gently inclining the vessel, that the sediment may not be disturbed; and the paste is thrown into large moulds proper for drying it. Before it is entirely hard, it is divided into small square cakes, which are sold by the hundred. The colour of this paste, and its form, have occasioned it to receive the name of pe-tun-tse.

The kao-lin, which is used in the composition of porcelain, requires less labour than the pe-tun-tse. Nature has a greater share in the preparation of it. There are large mines of it in the bosoms of certain mountains, the exterior strata of which consist of a kind of red earth. These mines are very deep, and the kao-lin is found in small lumps, that are formed into bricks after having gone through the same process as the pe-tun-tse. Father d'Entrecolles thinks, that the earth called terre de Malte, or St. Paul's earth, has much affinity to the kao-lin, although those small shining particles are not observed in it which are interspersed in the latter.

It is from the kao-lin that fine porcelain derives all its strength; if we may be allowed the expression, it stands it in the stead of nerves. It is very extraordinary, that a soft earth should give strength and consistency to the pe-tun-tse, which is procured from the hardest rocks. A rich Chinese merchant told father d'Entrecolles, that the English and Dutch had purchased some of the pe-tun-tse, which they transported to Europe with a design of making porcelain; but having carried with them none of the kao-lin, their attempt proved abortive, as they have since acknowledged. "They wanted," said this Chinese laughing, "to form a body, the flesh of which should support itself without bones."

The Chinese have discovered, within these few years, a new substance proper to be employed in the composition of porcelain. It is a stone, or rather species of chalk, called hoa-che, from which the physicians prepare a kind of draught that is said to be detersive, aperient, and cooling. The manufacturers of porcelain have thought proper to employ this stone instead of kao-lin. It is called hoa, because it is glutinous, and has a great resemblance to soap. Porcelain made with hoa-che is very rare, and much dearer than any other. It has an exceedingly fine grain; and with regard to the painting, if it is compared with that of the common porcelain, it appears to surpass it as much as vellum does paper. This porcelain is, besides, so light, that it surprises those who are accustomed to handle other kinds; it is also much more brittle; and it is very difficult to hit upon the proper degree of tempering it.

Hoa-che is seldom used in forming the body of the work; the artist is contented sometimes with making it into a very fine size, in which the vessel is plunged when dry, in order that it may receive a coat before it is painted and varnished; by these means it acquires a superior degree of beauty.

When hoa-che is taken from the mine, it is washed in rain or river water, to separate it from a kind of yellow earth which adheres to it. It is then pounded, put into a tub filled with water to dissolve it, and afterwards formed into cakes like kao-lin. We are assured that hoa-che, when prepared in this manner, without the mixture of any other earth, is alone sufficient to make porcelain. It serves instead of kao-lin; but it is much dearer. Kao-lin costs only ten-pence sterling; the price of hoa-che is half-a-crown; this difference, therefore, greatly enhances the value of porcelain made with the latter.

To pe-tun-tse and kao-lin, the two principal elements, must be added the oil or varnish from which it derives its splendour and whiteness. This oil is of a whitish colour, and is extracted from the same kind of stone which produces the pe-tun-tse; but the whitest is always chosen, and that which has the greenest spots. The oil is obtained from it by the same process used in making the pe-tun-tse: the stone is first washed and pulverised; it is then thrown into water, and after it has been purified it throws up a kind of cream. To 100 pounds of this cream is added one pound of che-kao, a mineral something like alum, which is put into the fire till it becomes red-hot, and then pounded. This mineral is a kind of runnet, and gives a consistence to the oil, which is however carefully preserved in its state of fluidity. The oil thus prepared is never employed alone; another oil must be mixed with it, which is extracted from lime and fern-ashes, to 100 pounds of which is also added a pound of che-kao. When these two oils are mixed, they must be equally thick; and in order to ascertain this, the workmen dip into each of them some cakes of the pe-tun-tse, and, by inspecting their surfaces closely after they are drawn out, thence judge of the thickness of the liquors. With regard to the quantity necessary to be employed, it is usual to mix ten measures of stone-oil with one measure of the oil made from lime and fern-ashes.

In forming vessels of porcelain, the first thing is to purify the pe-tun-tse and kao-lin, which, for the first, is done after the manner already described in preparing the squares; for the second it is sufficient to plunge it into an urn of water, in an open basket, as it will easily dissolve. The dregs that remain are perfectly useless, and are emptied out of the work-house when a quantity is got together.

To make a just mixture of pe-tun-tse and kao-lin, regard must be had to the fineness of the porcelain to be made; for the finer porcelain they use equal quantities; four parts of kao-lin to six of pe-tun-tse for moderate ones; and never less than one of kao-lin to three of pe-tun-tse for the coarsest. The hardest part of the work is the kneading and tewing the two earths together, which is done till the mass is well mixed, and grows hard, by the workmen trampling it continually with their feet. Then being taken out of the basons or pits wherein it is kneaded, it is done over a second time, but piecemeal, and with the hands, on large slates for that purpose: and on this preparation it is, that the perfection of the work depends; the least heterogeneous body remaining in the matter, or the least vacuity that may be found in it, being enough to spoil the whole. The porcelain is fashioned or formed either with the wheel like our earthenware, or in moulds. See Stone-ware.

Smooth pieces, as urns, cups, dishes, &c. are made with the wheel; the rest, such as are in relievo, as figures of men, animals, &c. are formed in moulds, but finished with the chisel. The large pieces are made at two operations: one piece is raised with the wheel by three or four workmen, who hold till it has acquired its proper figure: which done, they apply to it the other half, which has been formed in the same manner, uniting the two with porcelain-earth made liquid by adding water to it, and polishing the juncture with a kind of iron spatula. After the same manner it is that they join the several pieces of porcelain formed in moulds, or by the hand; and that they add handles, &c. to the cups, and other works formed by the wheel.

The moulds are made after the same manner with those of our sculptors, viz. of divers pieces which severally give their respective figure to the several parts of the model to be represented, and which are afterwards united to form a mould for an entire figure. The earth they are made of is yellow, and fat. Is is kneaded like potter's-earth; and when sufficiently mellow, fine, and moderately dry, beating it stoutly, they form it into moulds, according to the works required, either by hand, or on the wheel.

All the works that are made in moulds are finished by the hands, with several instruments proper to dig, smooth, polish, and to touch up, the strokes that escape the mould, so that it is rather a work of sculpture than of pottery. There are some works whereon relievos are added, ready-made, as dragons, flowers, &c. others that have an impression in creux, which last are engraved with a kind of puncheons. In general, all porcelain-works are to be sheltered from the cold; their natural humidity making them liable to break when they dry unequally.

PORCH. See Architecture.

PORCUPINE. See Histrix.

PORE, *in anatomy*, a little interstice or space between the parts of the skin, serving for perspiration. See Cutis, Perspiration, Physiology, &c.

PORELLA, in botany, a genus of mosses, the anthera of which is multilocular and foraminose.

POROSTEMA, a genus of the polyadelphia polyandria class and order. The calyx is six-parted; no corolla; filaments nine, with four anthers on each; capsules covered, six-celled. There is one species, a tree of Guiana.

PORPHYRY, a genus of stones belonging to the order of saxa. It is found of several different colours, as green, deep red, purple, black, dark brown, and grey. Under the name of porphyry, Mr. Kirwan and M. de Saussure include those stones which contain either feltspar, schoerl, quartz, or mica, with other species of crystallized stone on a siliceous or calcareous ground. There are a great many different kinds. M. Ferber describes twenty varieties under four species; but in general it is considered with relation to its ground, which is met with of the colours already mentioned. When the ground is of jasper, the porphyry is commonly very hard; the red generally contains feltspar in small white dots or specks, and frequently, together with these, black spots of schoerl. The green is often magnetic, and is either a jasper or schoerl, with spots of quartz. Sometimes a porphyry of one colour contains a fragment of another of a different colour. Those that have chert for their ground are fusible per se. The calcareous porphyry consists of quartz, feltspar, and mica, in separate grains, united by a calcareous cement; and, lastly, the micaceous porphyry consists of a greenish grey micaceous ground, in which red feltspar and greenish soap-rock are inserted.

The porphyry of the antients is a most elegant mass of an extremely firm and compact structure, remarkably heavy, and of a fine strong purple, variegated more or less with pale red and white; its purple is of all degrees, from the claret-colour to that of the violet; and its variegations are rarely disposed in veins, but spots, sometimes very small, and at others running into large blotches. It is less fine than many of the ordinary marbles; but it excels them all in hardness, and is capable of a most elegant polish. It is still found in immense strata in Egypt. The hard red lead coloured porphyry, variegated with black, white, and green, is a most beautiful and valuable substance. It has the hardness and all the other characters of the Oriental porphyry; and even greatly excels it in brightness and in the beauty and variegation of its colours. It is found in great plenty in the island of Minorca; and is well worth importing, being greatly superior to all the Italian marbles. The hard, pale-red porphyry, variegated with black, white, and green, is of a pale flesh-colour, often approaching to white. It is variegated in blotches from half an inch to an inch broad. It takes a high polish, and emulates all the qualities of the Oriental porphyry. It is found in immense strata in Arabia Petræa, and in the Upper Egypt; and in separate nodules in Germany, England, and Ireland.

Ficoroni takes notice of two exquisitely fine columns of black porphyry in a church at Rome. In Egypt there are three celebrated obelisks or pillars of porphyry; one near Cairo, and two at Alexandria. The French call them aguglias, and in England they are called Cleopatra's needles.

The art of cutting porphyry, practised by the antients, appears now to be lost. Indeed it is difficult to conceive what tools they used for fashioning those huge columns and other porphyry-works, in some of the antient buildings in Rome.

Da Costa, however, supposes, that the method used by the antients in cutting and engraving porphyry was extremely simple, and that it was performed without the aid of any scientific means that are now lost. He imagines, that, by unwearied diligence, and with numbers of common tools at great expence, they rudely hewed or broke the stone into the intended figures, and by continued application reduced them into more regular designs; and that they completed the work by polishing it with great labour, by the aid of particular hard sands found in Egypt. And he thinks, that in the porphyry-quarries there were layers of grit or loose disunited particles, analogous to the porphyry, which they carefully sought for, and used for this work.

PORT, a harbour or place of shelter, where ships arrive with their freight, and customs from goods are taken.

Port-holes, in a ship, are the holes in the side of the vessel, through which are put the muzzles of the great guns. These are shut up in storms, to prevent the water from driving through them. The English, Dutch, and French ships, have the valves or casements fastened at the top of the port-holes, and the Spanish vessels aside of them.

Port-royal, the name of two monasteries of cistercian nuns, in the diocese of Paris; the one near Chevreuse, at the distance of five leagues from Paris, called Port royal of the fields, and the other in Paris, in the suburbs of St. James's.

The nuns of the former of these monasteries, proving refractory, were dispersed; when many ecclesiastics, and others, who were of the same sentiments as these religious, retired to Port Royal, took apartments there, and printed many books; hence the name of Port-royalists was given to all their party, and their books were called books of Port-royal; hence we say the writers of Port-royal, messieurs de Port-royal, and the translations and grammars of Port-royal.

PORTA, or VENA PORTA. See ANATOMY.

PORTERAGE. By stat. 39 Geo. III. c. 58, no inn-keeper, warehouse-keeper, or other person, to whom any box, basket, package, parcel, truss, game, or other thing whatsoever, not exceeding fifty-six pounds weight, or any porter or other person employed by such inn-keeper, warehouse-keeper, or other person, in porterage, or delivery of any such box, parcel, &c. within the cities of London, Westminster, or borough of Southwark, and their respective suburbs, and other parts contiguous, not exceeding half a mile from the end of the carriage-pavement, in the several streets and places within the abovementioned limits, shall ask or demand, or receive or take, in respect of such porterage or delivery, any greater rate or price than as follows:

Not exceeding a	quarter of a mile	3*d*.
————	half a mile	4*d*.
————	one mile	6*d*.
————	one mile and a half	8*d*.
————	two miles	10*d*.

For every further distance, not exceeding half a mile, three-pence additional.

Persons asking or receiving more than the above rates, shall for every such offence, forfeit a sum not exceeding 20*s*. nor less than 5*s*.

PORTICO. See ARCHITECTURE.

PORTLAND STONE is a dull whitish species much used in buildings about London. It is composed of a coarse grit, cemented together by an earthy spar. It will not strike fire with steel, but makes a violent effervescence with nitric acid. See FREESTONE.

PORTLANDIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is elevated and funnel-shaped; the antheræ are longitudinal; the capsule pentagonal, and retuse at top, bilocular, and crowned with a pentaphyllous calyx. There are four species. The grandiflora has been particularly described by Dr. Browne, who has also given a good figure of it. It has frequently flowered in the royal garden at Kew, and in Dr. Pitcairn's at Islington. The external bark is remarkably rough, furrowed, and thick: it has no taste. The inner bark is very thin, and of a dark-brown colour. Its taste is bitter and astringent, and its virtues are the same as those of the Jesuits' bark. Infused in spirits or wine with a little orange-peel, it makes an excellent stomachic tincture.

PORTRAIT. See PAINTING.

PORTULACA, *purslane*, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The corolla is pentapetalous; the calyx bifid; the capsule unilocular, and cut round. There are 12 species, but the two following are the most remarkable: 1. The oleracea, annual, or common culinary purslane. There are two varieties; one with deep-green leaves, the other with yellow leaves; both of which rise from the same seed. 2. The anacampseros, perennial, or shrubby Cape purslane. Both these plants are of a succulent nature: the first is an herbaceous annual, for culinary uses; and the second a shrubby perennial, raised by the curious for variety. They are both exotics of a tender quality, of the temperature of greenhouse or stove plants. The common culinary purslane is raised annually from seed for summer use, and is an excellent ingredient in summer salads, but improper for winter on account of its cold moist nature. The plant being tender, must be raised either on a hotbed or in a warm border.

PORTULACARIA, a genus of the class and order pentandria trigynia. The calyx is two-leaved; the petals five; seed one, three-sided and winged. There is one species, called purslane-tree.

POSITION. See ARCHITECTURE.

POSITION, or the *rule of false position*, otherwise called the *rule of falsehood*, in arithmetic, is a rule so called, because in calculating on several false numbers taken at random, as if they were the true ones, and from the differences found therein, the number sought is determined. This rule is either single or double. Single position is when there happens in the proposition some partition of numbers into parts proportional, in which case the question may be resolved at one operation, by this rule: Imagine a number at pleasure, and work therewith according to the tenor of the question, as if it were the true number; and what proportion there is between the false conclusion and the false proportion, such proportion the given number has to the number sought.

Therefore the number found by argumentation, shall be the first term of the rule of three; the second number supposed, the second term; and the given number, the third. See ARITHMETIC. Or the result is to be regulated by this proportion, viz. As the total arising from the error, to the true total, so is the supposed part, to the true one. Example: A, B, and C, designing to buy a quantity of lead to the value of 140*l*. agree that B shall pay as much again as A, and C as much again as B; what then must each pay?

Now suppose A to pay 10*l*. then B must pay 20*l*. and C 40*l*. the total of which is 70*l*. but it should be 140*l*. Therefore, if 70*l*. should be 140*l*. what should 10*l*. be?

Answer, 20*l*. for A's share, which doubled, makes 40*l*. for B's share, and that again doubled, gives 80*l*. for C's share, the total of which is 140*l*.

Double position, is when there can be no partition in the numbers to make a proportion. In this case, therefore, you must make a supposition twice, proceeding therein according to the tenor of the question. If neither of the supposed numbers solves the proportion, observe the errors, and whether they are greater or less than the supposition requires, and mark the errors accordingly with the sign + or —. See CHARACTER.

Then multiply contrariwise the one position by the other error; and if the errors are both too great, or both too little, subtract the one product from the other, and divide the difference of the products by the difference of the errors. If the errors are unlike, as the one + and the other —, add the products, and divide the sum thereof by the sum of the errors added together; for the proportion of the errors is the same with the proportion of the excesses or defects of the numbers supposed to be the numbers sought; or the suppositions and their errors being placed as before, work by this proportion as a general rule, viz. as the difference of the errors if alike, or their sum if alike, to the difference of the suppositions, so either error, to a fourth number; which accordingly added to or subtracted from the supposition against it, will answer the question.

POSITION, in geometry, is a term sometimes used in contradistinction to magnitude: thus, a line is said to be given in position, positione data, when its situation, bearing, or direction, with regard to some other line, is given; on the contrary, a line is given in magnitude when its length is given, but not its situation.

POSSE COMITATUS. See POWER OF THE COUNTY.

POSSESSION is two-fold, actual and in law. Actual possession is when a man actually enters into lands and tenements to him descended. Possession in law, is when the lands or tenements are descended to a man, and he has not as yet actually entered into them. Staundf. 198.

POST, a military station. Thus the detachments established in front of the army are termed out-posts; the stations on the wings of the army are said to be the posts of honour, as being the most conspicuous and most exposed. But in the operations of a campaign, a post properly signifies any spot of ground capable of lodging soldiers; or any situation, whether fortified or not, where a body of men may make a stand and engage the enemy to advantage. The great advantages of good posts, in carrying on war, as well as the mode of securing them, are only learned by experience. Barbarous nations disdain the choice of posts, or at least are contented with such as immediately fall in their way; they trust solely or chiefly to strength and courage: and hence the fate of a kingdom may be decided by the event of a battle. But enlightened and experienced officers make the choice of posts a principal object of attention. The use of them is chiefly felt in a defensive war against an invading enemy; as, by carrying on a war of posts in a country where this can be done to advantage, the most formidable army may be so harassed and reduced, that all its enterprises may be rendered abortive.

In the choice of a post, the general rules to be attended to are, that it should be convenient for sending out parties to reconnoitre, surprise, or intercept the enemy; that if possible it may have some natural defence, as a wood, a river, or a morass, in front or flank, or at least that it be difficult of access, and susceptible of speedy fortification; that it shall be so situated as to preserve a communication with the main army, and have covered places in the rear to favour a retreat; that it may command a view of all the approaches to it, so that the enemy cannot advance unperceived and rest concealed, while the detachment stationed in the posare forced to remain under arms; that it is not commanded by any neighbouring heights; and proportioned in extent to the number of men who are to occupy and defend it. It is not to be expected that all these advantages will often be found united; but those posts ought to be selected which offer the greatest number of them.

POST, an operation in book-keeping. See BOOK-KEEPING.

POST, a conveyance for letters or dispatches. England appears to be the first country in Europe, which formed a regular establishment for this purpose: though it was not till a late period that it assumed any thing like a regular form even here. In the reign of Edward VI., however, some species of posts must have been set up, as an act of parliament passed in 1548, fixing the rate of post-horses at one penny per mile: the post-horses here referred to were, it is probable, chiefly for travelling, and the carriage of letters or packets only an occasional service. In 1581, we find in Camden's Annals mention made of a chief postmaster for England being appointed. How his office was managed, does not clearly appear; the limited state of the correspondence of the country probably rendered it of trifling consequence. King James I. originally erected a post-office under the controul of one Matthew de Quester, or de l'Equester, for the conveyance of letters to and from foreign parts; which office was afterwards claimed by lord Stanhope, but was confirmed and continued to William Frizel and Thomas Witherings, by king Charles I., in 1632. Previous to this time, it would appear that private persons were in the habit of conveying letters to and from foreign parts; all such interference with the postmaster's office is, therefore, expressly prohibited. King Charles, in 1635, erected a letter-office for England and Scotland, under the direction of the above Thomas Witherings. The rates of postage then established were, two-pence for every single letter for a distance under 80 miles; four-pence from 80 to 140 miles; six-pence above 140 miles. The allowance to the post-masters on the road for horses employed in these posts, was fixed at two-pence halfpenny per mile for every single horse. All private inland posts were discharged at this time; and in 1637, all private foreign posts were in like manner prohibited. The posts thus established, however, extended only to a few of the principal roads; and the times of transmission were not in every case so certain as they ought to have been.

Witherings was superseded for abuses in the execution of his offices in 1640, and they were sequestrated into the hands of Philip Burlamachy, to be exercised under the care and oversight of the king's principal secretary of state. On the breaking out of the civil war, great confusions and interruptions were necessarily occasioned in the conduct of the letter-office; but it was about that time that the outline of the present more extended and regular plan seems to have been conceived by Mr. Edmond Prideaux, who was afterwards appointed attorney-general to the commonwealth. He was chairman of a committee in 1642, for considering the rate of postage to be set upon inland letters; and some time was appointed postmaster by an ordinance of both houses of parliament, in the execution of which office he first established a weekly conveyance of letters into all parts of the nation. In 1653, this revenue was farmed for 10,000*l.* for England, Scotland, and Ireland; and after the charge of maintaining postmasters, to the amount of 7000*l.* per annum was saved to the public. Prideaux's emoluments being considerable, the common council of London endeavoured to erect another post-office in opposition to his; but they were checked by a resolution of the house of commons, declaring that the office of postmaster is, and ought to be, in the sole power and disposal of the parliament. This office was farmed by one Maubey, in 1654. In 1656, a new and regular general post-office was erected by the authority of the Protector and his parliament, upon nearly the same model that has been ever since adopted, with the following rates of postage: for 80 miles distance, a single letter two-pence; for a greater distance, not out of England, three-pence; to Scotland, four-pence. By an act of parliament passed soon after the Restoration in 1660, the regulations settled in 1656 were re-established, and a general post-office similar to the former, but with some improvements, was erected. In 1663, the revenue of the post-office was found to produce 21,500*l.* annually. In 1685, it was made over to the king, as a branch of his private income, and was then estimated at 65,000*l.* per annum. The year after the Revolution, the amount of the post-office revenue was 90,504*l.* 10*s.* 6*d.* At the Union, the produce of the English post-office was stated to be 101,101*l.* In 1711, the former establishments of separate post-offices for England and Scotland were abolished; and by the stat. 9 Anne, c. 10. one general post-office, and one postmaster-general, were established for the whole united kingdom; and this postmaster was empowered to erect chief letter-offices at Edinburgh, at Dublin, at New York, and other proper places in America, and the West Indies. The rates of postage were also increased at this time, as follows: In England, for all distances under 80 miles, three-pence; above 80 miles, four-pence. From London to Edinburgh, six-pence. In Scotland, under 50 miles, two-pence; from 50 to 80 miles, three-pence; above 80 miles, four-pence. In Ireland, under 40 miles, two-pence; above 40 miles, four-pence. By the above act, all persons, except those employed by the postmaster, were strictly prohibited from conveying letters. That year the gross amount of the post-office was 111,461*l.* 17*s.* 10*d.* The net amount, on a medium of the three preceding years, was, in the printed report of the commissioners for the equivalent, stated to be for England, 62,000*l.*, and for Scotland, 2000*l.* In 1754, the gross revenue of the post-office for Great Britain amounted to 210,663*l.*; in 1764, to 281,535*l.*; and in 1774 to 345,321*l.* The privilege of franking letters had been enjoyed by members of parliament from the first erection of the post-office; the original design of this exemption was, that they might correspond freely with their constituents on the business of the nation. By degrees the privilege came to be shamefully abused, and was carried so far, that it was not uncommon for the servants of members of parliament to procure a number of franks for the purpose of selling them; an abuse which was easily practised, as nothing more was required for a letter's passing free than the subscription of a member on the cover. To restrain these frauds, it was enacted, in 1764, that no letter should pass free unless the whole direction was of the member's writing, and his subscription annexed. Even this was found too great a latitude; and by a new regulation in 1784, no letter was permitted to go free, unless the date was marked on the cover in the member's own handwriting, and the letter put into the office the same day. That year the rates of postage were raised in the following proportions: an addition of one penny for a single stage; one penny from London to Edinburgh; one penny for any distance under, and two-pence for any distance above 150 miles. An addition to the revenue of 120,000*l.* was estimated to arise from these regulations and additional rates. In all the statements of duties upon postage of letters given in this account, the rates mentioned are those upon single letters: double letters pay double, treble letters treble, an ounce weight quadruple postage; all above are charged by the weight, in the same proportion.

About the year 1784, a great improvement was made in the mode of conveying the mails, upon a plan first suggested in 1782, by Mr. John Palmer. Diligences and stage-coaches, he observed, were established to every town of note in the kingdom; and he proposed that government, instead of sending the mails in the old mode, by a boy on horseback, and in carts, should contract with the masters of these diligences to carry the mail, along with a guard for its protection. This plan, he shewed, could not fail to ensure much more expeditious conveyance, the rate of travelling in diligences being far quicker than the rate of the post; and it was easy to carry it into execution with little additional expence, as the coach-owners would have a strong inducement to contract at a cheap rate for conveying the mail, on account of the additional recommendation to passengers, their carriages would thereby acquire in point of security, regularity, and dispatch. Though government heartily approved of this plan, and the public at large were satisfied of its utility, yet, like all new schemes however beneficial, it met with a strong opposition: it was represented by a number of the oldest and ablest officers in the post-office, not only as impracticable, but dangerous to commerce and the revenue. Notwithstanding this opposition, however, it was at last established, and gradually extended to many different parts of the kingdom; and, upon a fair comparison, it appeared that the revenue was very considerably improved, though Mr. Palmer's numerous reforms, and the great number of new appointments which they rendered necessary, greatly increased the former expence of management. The conveyance of the mails on the new plan was contracted for, after the two first years trial, at 20,000*l.* per annum less than the sum first estimated by Mr. Palmer.

The present establishment of the general post-office for Great Britain, consists of a postmaster-general, to the duties of which station there have, for many years past, been two persons appointed, under the title of joint postmasters-general; a secretary; upwards of 150 assistants and clerks for the head letter-office in London, under the direction of a superintending president of the inland-letter department; and a comptroller of the foreign-letter office. Near 600 deputy-postmasters, throughout the kingdom, act under one principal and nine riding surveyors. There are also distinct offices and clerks, acting under an accountant-general and a receiver-general; as well as a separate establishment for the two-penny, formerly the penny-post, which, since the abolition of Mr. Palmer's appointment of surveyor and comptroller-general, has been new modelled and greatly improved in all its branches. There is likewise a postmaster-general of Scotland, with a secretary, comptroller, surveyors, and a separate establishment of all the requisite officers and clerks at Edinburgh, acting under the orders of the joint postmasters-general in London. The annual expence of management is about 150,000*l.* and the gross produce exceeds 700,000*l.* a year.

For the present rates of postage, and the laws respecting franking, see Letter.

No action can be maintained against the postmaster-general for the loss of bills or articles sent in letters by the post, and lost. Many attempts have been made by postmasters in country towns, to charge an halfpenny or penny each letter, on delivery at the houses in the town, above the parliamentary rates, under pretence that they were not obliged to carry letters out of the office gratis; but it has been repeatedly decided, that such demand is illegal, and that they are bound to deliver the letters to the inhabitants within the usual and established limits of the town, without any addition to the rate of postage. 5 Bur. 5709.

Post *two-penny*, a post established for the benefit of London, and other parts adjacent, whereby any letter or small parcel is speedily and safely conveyed to and from all places within the bills of mortality, or within ten miles of the city. It is now managed by the general post-office, and receiving-houses are established in most of the principal streets for the more convenient transmission of the letters.

Letters were originally conveyed by this office at the rate of one-penny; but the rate has been lately raised to two-pence, and for letters off the stones the rate is three-pence.

Post, a particular mode of travelling. A person is said to travel post, in contradistinction to common journey travelling, when, in place of going on during his whole journey in the same vehicle, and with the same horses, he stops at different stages, to provide fresh horses or carriages, for the sake of greater convenience and expedition. As he thus uses the same mode of travelling that is employed for the common post, he is said to travel post, or in post, *i. e.* in the manner of a post.

In tracing the origin of posts, it appears that the more antient establishments of this kind were fully as much for travelling stations as the conveyance of letters. The relays of horses provided at these public stations for the messengers of the prince, were occasionally, by special licence, allowed to be used by other travellers who had sufficient interest at court. Frequent demands of this nature would suggest the expedient of having in readiness supplies of fresh horses or carriages over and above what the public service required, to be hired out to other travellers on payment of an adequate price. We find, therefore, that in former times, the postmasters alone were in use to let out horses for riding post, the rates of which were fixed in 1548, by a statute of Edward VI., at one penny per mile. In what situation the state of the kingdom was with regard to travelling post for more than a century after this period, we cannot now certainly discover; but in the statute re-establishing the post-office in 1660, it is enacted, that none but the postmaster, his deputies, or assigns, shall furnish post-horses for travellers; with a proviso, however, that if he has them not ready in half an hour after being demanded, the traveller shall be at liberty to provide himself elsewhere. The same prohibition is contained in the act establishing the Scots post-office in 1695, as well as in the subsequent act of queen Anne, erecting the general office for the united kingdom. It is doubtful, however, whether it ever was strictly enforced. By an explanatory act of 26 Geo. II. the prohibition is confined to post horses only, and every person declared to be at liberty to furnish carriages of every kind for riding post. This regulation has, in fact, done away the prohibition, as hardly any person now thinks of travelling post, except in a carriage.

The rate fixed by the act 1695, in Scotland, for a horse riding post, was three-pence per Scotch mile. By the act 9. Anne, c. 10. three-pence a mile without, and four-pence a mile with, a guide, was the sum fixed for each horse riding post. The increase of commerce, and necessity for a speedy communication between different parts of the kingdom, have brought the mode of travelling post so much into use, that upon every great road in the kingdom, post chaises are now in readiness at proper distances; and the convenience of posting is enjoyed in Britain to a degree far superior to what is to be met with in any other country whatever.

Posting at last appeared to the legislature a proper object of taxation. In 1779 the first act was passed, imposing duties on horses hired either by themselves or to run in carriages travelling post; the duties were, one penny per mile on each horse if hired by the mile or stage, and one shilling per day if hired by the day. Every person letting out such horses was also obliged to take out a licence at five shillings per annum. These duties were next year repealed, and new duties imposed, of one penny per mile on each horse hired by the mile or stage, and one shilling and six-pence on each if hired by the day. A number of additional regulations were at the same time enacted for securing these duties. An addition of one halfpenny per mile, or three-pence per day, for each horse riding post, was imposed in 1785, by stat. 25 Geo. III. c. 51. The duty is secured by obliging every letter of horses to deliver to the person hiring them a ticket, expressing the number of horses hired, and either the distance in miles to be travelled, or that the horses are hired by the day, as the case happens to be. These tickets must be delivered to the bar-keeper at the first turnpike through which the traveller passes; and the turnpike-keeper gives, if demanded, what is termed an exchange ticket, to be produced at the next turnpike. The stamp-office issues to the person licenced to let post horses such a number of these tickets as is required, and these must be regularly accounted for by the person to whom they are issued. As an effectual check upon his account, the turnpike-keeper is obliged to return back to the stamp-office all the tickets he takes up from travellers. Evasions are by these means rendered difficult to be practised without running a great risk of detection. In 1787, for the more effectually levying the post-horse duties, a law was passed authorising the commissioners of the stamp-office to let them to farm by public auction, for a sum not less than the produce in the year ending 1st August 1786.

In the advertisement published by the commissioners in consequence of this law, previous to the receiving proposals for farming them, the total amount of the duty for Great Britain is stated to have been, at the period above referred to, 119,873*l.* The sum for which that duty was farmed in 1794, amouted in all to 140,030*l.* of which the district of North Britain was 6000*l.*

POST DISSEISIN, a writ for him that having recovered land or tenements by præcipe quod reddat, upon default of reddition is again disseised by the former disseisor.

POSTEA, is the return of the proceedings by nisi prius into the court of common pleas after a verdict, and there afterwards recorded. Plowd. 211.

POSTERN, in fortification, is a small gate generally made in the angle of the flank of a bastion, or in that of the curtin, or near the orillon, descending into the ditch; by which the garrison may march in and out unperceived by the enemy, either to relieve the works, or to make private sallies, &c.

POSTULATE, in mathematics, &c., is described to be such an easy, and self-evident supposition, as needs no explication or illustration to render it intelligible; as, that a right line may be drawn from one point to another.

POTAMOGETON, *pond-weed*, a genus of the tetrandria tetragynia class of plants, the corolla whereof consists of four roundish obtuse, hollow, patent, and unguiculated petals: there is no pericarpium; the seeds are four in number, roundish and accuminated, gibbous on one side, and compressed and angulated on the other. This plant has a refrigerating virtue, and is recommended in the cure of old ulcers. There are 14 species.

POTASS. If a sufficient quantity of wood is burnt to ashes, and these ashes afterwards washed repeatedly with water till it comes off free from any taste, and if this liquid is filtrated and evaporated to dryness, the substance which remains behind is potass; not, however, in a state of purity, for it is contaminated with several other substances, but sufficiently pure to exhibit many of its properties. In this state it occurs in commerce under the name of potash. When heated to redness, many of its impurities are burnt off; it becomes much whiter than before, and is then known in commerce by the name of pearl-ash. Still, however, it is contaminated with many foreign bodies, and is itself combined with carbonic acid gas, which blunts all its properties. It may be obtained perfectly pure by the following process:

1. Mix it with twice its weight of quick-lime, and ten times its weight of pure water. Boil the mixture for some hours in a clean iron vessel, or allow it to remain for 48 hours in a close glass vessel, shaking it occasionally. Then pass it through a filter. Boil the liquid obtained in a silver vessel very rapidly, till it is so much concentrated as to assume when cold the consistence of honey. Then pour upon it a quantity of alcohol equal in weight to one-third of the pearl-ash employed. Shake the mixture, put it on the fire, let it boil for a minute or two, then pour it into a glass ves-

sel and cork it up. The solution gradually separates itself into two strata: the lowest consists of the impurities, partly dissolved in water and partly in a solid state; the uppermost consists of the pure potass dissolved in alcohol, and is of a reddish-brown colour. Decant this alcohol solution into a silver bason, and evaporate it rapidly till a black charry crust forms on the surface, and the liquid below acquires such consistence as to become solid on cooling. Then remove the black crust, and pour the solution into a porcelain vessel. When cold, it concretes into a fine white substance, which is pure potass. It must be broken to pieces, and put into an air-tight phial.

For this process we are indebted to Berthollet. The following, which was proposed by Lowitz of Petersburgh, is less expensive. The potash of commerce and quicklime are to be boiled together as above described. The filtered liquor is then to be evaporated till a thick pellicle appears on its surface, and afterwards allowed to cool; and all the crystals which have formed are to be separated, for they consist of foreign salts. The evaporation is then to be continued in an iron pot; and, during the process, the pellicle which forms on the surface is to be carefully taken off with an iron skimmer. When no more pellicle appears, and when the matter ceases to boil, it is to be taken off the fire, and must be constantly agitated with an iron spatula while cooling. It is then to be dissolved in double its own weight of cold water. This solution is to be filtered and evaporated in a retort (not of glass, because potass in this state dissolves glass), till it begins to deposit regular crystals. If the mass consolidates ever so little by cooling, a small quantity of water is to be added, and it must be heated again. When a sufficient number of crystals have been formed, the liquor which swims over them, and which has assumed a very brown colour, must be decanted off, and kept in a well-closed bottle till the brown matter has subsided, and then it may be evaporated as before, and more crystals obtained.

The theory of these processes is obvious: the lime separates the carbonic acid, for which it has a stronger affinity; and the alcohol or the evaporation separate all the other foreign ingredients.

As potass is never obtained at first in a state of purity, but always combined with carbonic acid, it was long before chemists understood to what the changes produced upon it by lime were owing. At last, in 1756, Dr. Black proved, by the most ingenious and satisfactory analysis, that the potass which the world had considered as a simple substance, was really a compound, consisting of potass and carbonic acid; that lime deprived it of this acid; and that it became more active by becoming more simple.

That potass was known to the antient Gauls and Germans cannot be doubted, as they were the inventors of soap, which, Pliny informs us, they composed of ashes and tallow. These ashes (for he mentions the ashes of the beech tree particularly), were nothing else but potass; not, however, in a state of purity. The κονια, too, mentioned by Aristophanes and Plato, appears to have been a ley made of the same kind of ashes. The alchymists were well acquainted with it; and it has been in every period very much employed in chemical researches. It was long distinguished among us by the name of vegetable alkali, because it is obtained from vegetables, and because it was long thought to be peculiar to the vegetable kingdom; but this is now known to be a mistake. It was called also salt of tartar, because it may be obtained by burning the salt called tartar. Mr. Kirwan has given it the name of tartarin, Dr. Pearson has called it vegalkali, Klaproth kali, and Dr. Black lixiva. By most British chemists it is called potash: but this term, in common language, signifies the carbonat of potass, or the potass of commerce. For in fact, till Berthollet published his process in the year 1786, chemists had never examined potass in a state of complete purity.

2. Potass is a brittle substance of a white colour, and a smell resembling that which is perceived during the slacking of quicklime. Its taste is remarkably acrid; and it is so exceedingly corrosive, that when applied to any part of the body, it destroys it almost instantaneously. On account of this property, it has been called caustic, and is often used by surgeons under the name of the potential cautery, to open abcesses, and to destroy useless or hurtful excrescences. Its specific gravity is 1.70.

When heated it melts; at a red heat it swells, and evaporates slowly in a white acrid smoke. A strong heat gives it a greenish tinge, but produces no other alteration in it. Potass is not altered by exposure to light.

When exposed to the air, it soon attracts moisture, and is converted into a liquid; at the same time it combines with carbonic acid, for which it has a strong affinity.

3. It has a very strong affinity for water. At the common temperature of the air, one part of water dissolves two parts of potass. The solution is transparent, very dense, and almost of the consistence of oil. It is in this state that potass is usually employed by chemists. When four parts of potass in powder, and one of snow are mixed together, the mixture becomes liquid, and at the same time absorbs a quantity of caloric. This mixture was employed by Lowitz to produce artificial cold. When the aqueous solution of potass is evaporated to a proper consistency, the potass crystallizes. The shape of its crystals is very different, according to the way in which they have been produced. When allowed to form spontaneously, they are octahedrons in groups, and contain 0.43 of water. When formed by evaporation on the fire, they assume the figure of very thin transparent blades of extraordinary magnitude, which, by an assemblage of lines crossing each other in prodigious numbers, present an aggregate of cells or cavities, commonly so very close, that the vessel may be inverted without losing one drop of the liquid which it contains.

4. Potass shews no disposition to unite with oxygen, neither is it altered by the action of any of the compounds into which oxygen enters, though it has a strong tendency to unite with several of these compounds.

5. It unites with none of the simple combustibles except sulphur. Carbon and hydrogen do not act upon it at all; neither does it produce any alteration in them, but it acts upon phosphorus with considerable energy.

When three parts of sulphur and one of potass are triturated together in a glass mortar, the sulphur acquires a green colour, the mixture becomes hot, and exhales an aliaceous odour. It gradually attracts moisture from the air, and is totally soluble in water. When two parts of potass and one of sulphur are heated in a crucible, they melt and combine, and form sulphuret of potass. The potash of commerce may be also employed; for the carbonic acid separates in the form of a gas during the combination of the potass and sulphur. When the fusion is complete, the sulphuret is to be poured upon a marble slab; and as soon as it congeals, it must be broken to pieces, and set by into a well-corked phial.

Sulphuret of potass, thus prepared, is of a brown colour, not unlike the liver of animals. Hence it was formerly called hepar sulphuris, "liver of sulphur;" but when exposed to the air, it soon becomes green, and even white. It is hard, brittle, and has a glassy fracture. Its taste is acrid, caustic, and bitter, and it leaves a brown stain upon the skin. It has no other smell than that of sublimed sulphur. When exposed to a violent heat the sulphur sublimes, and the potass remains in a state of purity. This sulphuret converts vegetable blues to green, and soon destroys them. When heated with charcoal, it dissolves, and combines with it.

When sulphuret of potass is exposed to the air, or when it is moistened with water, its properties very soon change. It acquires a green colour, and exhales the odour of sulphureted hydrogen gas. This change is owing to the formation of a quantity of sulphureted hydrogen, in consequence of the decomposition of the water. This new-formed substance combines with the sulphuret, and converts it into hydrogenated sulphuret of potass, which is soluble in water, and has a brownish green colour. It may be formed also by boiling in water two parts of potass and one part of sulphur. Sulphuret of potass produces no change upon air, but hydrogenated sulphuret gradually absorbs oxygen. When inclosed in a vessel with a quantity of air, it soon absorbs all the oxygen of that portion, and leaves nothing but azotic gas. This fact, which was first observed by Scheele, induced him to use hydrogenated sulphuret to measure the quantity of oxygen contained in any given portion of atmospheric air. Hydrogenated sulphuret is capable of oxydizing and dissolving almost all the metals. We are indebted to M. Berthollet for the first accurate account of the difference between these two substances.

Potass cannot be combined with phosphorus by any method at present known. But when potass, dissolved in water, is heated over phosphorus in a retort, the water is gradually decomposed, part of the phosphorus is converted into phosphoric acid, and a great quantity of phosphureted hydrogen gas is emitted, which takes fire as usual as soon as it comes into contact with the air of the atmosphere. It was by this process that Gemgembre first obtained phosphureted hydrogen gas.

6. It does not appear that potass is capable of uniting with azote, or even of acting on it at all; but with muriatic acid it unites very readily, and forms the compound known by the name of muriat of soda.

7. Potass does not combine with any of the metals; but some of the metals which

have a strong affinity for oxygen, when put into a solution of potass in water, especially if heat is applied, are gradually oxydized. This is the case with molybdenum, zinc, and iron. Tin also is oxydized in a very small proportion; and this seems also to be the case with manganese.

It is capable of dissolving a considerable number of the metallic oxides; and in some cases it deprives them of a dose of their oxygen. Thus, when poured upon the red oxide of iron it soon converts it into the black. The cause of this change is unknown. It has been ascertained, that the oxides of the following metals are soluble in potass.

Tin,	Arsenic,
Nickel,	Cobalt,
Zinc,	Manganese,
Antimony,	Tungsten,
Tellurium,	Molybdenum.

But the nature of these solutions has not hitherto been examined with any degree of attention; though the subject is remarkably curious, and promises to throw light both upon the nature of alkalies and metals.

The affinities of potass are as follow:

Sulphuric acid,	Citric,
Nitric,	Lactic,
Muriatic,	Benzoic,
Phosphoric,	Sulphurous,
Fluoric,	Acetic,
Oxalic,	Saclactic,
Tartaric,	Boracic,
Arsenic,	Carbonic,
Succinic,	Prussic.

Potass has never yet been decomposed. Several chemists, indeed, have conjectured, that it is a compound of lime and azote; and some persons have even endeavoured to prove this by experiment; but none of their proofs are at all satisfactory. We ought, therefore, perhaps, in strict propriety, to have assigned it a place among our enumeration of simple bodies in the article chemistry; but as it is excluded by most of the foreign chemists, we thought it least likely to promote confusion to follow their arrangement. Besides, we are certain, from a variety of facts, that all the alkalies are compounds. One of them has actually been decompounded; and the other two have been detected in the act of formation, though the ingredients which compose them have not hitherto been discovered. Morveau and Desormes indeed announced, some time ago, that they considered potass as a compound of hydrogen and lime. Their chief proofs were the appearance of lime, when the salt, composed of hyperoxygenized muriatic acid and potass, is strongly heated with phosphoric acid in a crucible of platinum; and a manifest combustion together with the deposition of lime, when charcoal and potass are in like manner exposed to a strong heat in a platinum crucible. But these, and the other experimental proofs, being examined by Darracq, that accurate chemist ascertained that the results obtained by Desormes and Morveau were owing, in most cases, to the impurity of the potass with which they had made their experiments; while in others, they had drawn wrong inferences from mistaken resemblances. Their hypothesis of course cannot be maintained.

Potass is of the highest importance, not only in chemistry, where it is employed for a great variety of purposes, but also in many arts, and manufactures; as washing, bleaching, dying, glass-making, and others, as will appear on an inspection of these articles. It is employed also in surgery and medicine.

POTATOE. See SOLANUM.

POTENT, or POTENCE, in heraldry, a term for a kind of a cross, whose ends all terminate like the head of a crutch.

POTENTILLA, *silver-weed, wild tansey*, or *cinquefoil*, a genus of the pentagynia order, in the icosandria class of plants, and in the natural method ranking under the 35th order senticosæ. The calyx is decemfid; there are five petals; the seeds roundish, naked, and affixed to a small dry receptacle. There are 32 species, the most noted are:

1. The fruticosa, or shrubby potentilla, commonly called shrub-cinquefoil. This is a beautiful deciduous flowering shrub, worthy a place in every curious collection. It grows wild in Yorkshire, and other northern parts of England, &c. but has been long cultivated in gardens as an ornamental shrub. 2. The reptans, or creeping common five-leaved potentilla, or five-leaved grass. 3. The rupestris, or mountain upright cinquefoil, having the stalks terminated by small white flowers. 4. The recta, or erect seven-lobed yellow cinquefoil, has the stalks terminated by corymbose clusters of yellow flowers. 5. The fragaroides, or strawberry-like trailing potentilla. This species bears a great resemblance to the small sterile strawberry plants. 6. The argentea, silvery upright potentilla, with small yellow flowers,

All these plants flower in June and July; the flowers are composed each of five roundish petals, and about 20 stamina. They are all very hardy, and may be employed in the different compartments of the pleasure ground. Their propagation is very easy.

POTERIUM, *garden burnet*, a genus of the polyandria order, in the monœcia class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The male calyx is tetraphyllous; the corolla quadripartite; and there are from 30 to 40 stamina. The female calyx is tetraphyllous; the corolla quadripartite; there are two pistils; the berry is formed of the indurated tube of the corolla. There are five species, the most remarkable are: 1. The sanguisorba, or common garden burnet. This species grows wild in England in chalky soils, but has been long cultivated as a sallad-herb for winter and spring use, it being of a warm nature; the young leaves are the useful parts. It is perennial in root, and retains its radical leaves all the year, but the stalks are annual. 2. The hybridum, hybrid agrimony-leaved Montpelier burnet. This species often proves biennial; but, by cutting down some of the stalks before they flower, it will cause it to multiply at bottom, and become abiding. 3. Poterium spinosum, shrubby spinous burnet of Crete.

Burnet is of a cordial nature; in summer, the leaves are used for cool tankards, to give the wine an agreeable flavour. The powder of the root of the first species is commended against spitting of blood, bleeding at the nose, dysenteries, and diseases attended with violent secretions. In winter and spring, the young tender leaves are used in salads. Its uses as food for cattle are well known.

POTHOS, a genus of the polyandria order, in the gynandria class of plants. The spatha or sheath is a simple spadix covered; there is no calyx, but four petals, and as many stamina; the berries dispermous.

POTSTONE, a mineral found in nests and beds, and is always amorphous. Its structure is often slaty; fracture undulatingly foliated, greasy and brittle. Specific gravity from 2.85 to 3.02. Colour grey, with a shade of green, and sometimes of red or yellow, sometimes leek-green and sometimes speckled with red. Potstone is not much affected by the fire, and is made into utensils for boiling water: hence its name. It consists of

38	magnesia
38	silica
7	alumina
5	iron
1	carbonat of lime
1	fluoric acid.

POTTERY, the manufacture of earthen ware, or the art of making earthen vessels. In a general sense, therefore, it applies to all the different branches. See DELFT-WARE, STONE-WARE, and PORCELAIN, &c. In a more particular sense it is confined to the coarser kinds, such as the making of garden-pots, &c. The wheel and lathe are the chief and almost the only instruments in pottery: the first for large works, and the last for small. The potter's wheel consists principally in the nut, which is a beam or axis, whose foot or pivot, plays perpendicularly on a freestone sole or bottom. From the four corners of this beam, which does not exceed two feet in height, arise four iron bars, called the spokes of the wheel; which forming diagonal lines with the beam, descend, and are fastened at bottom to the edges of a strong wooden circle, four feet in diameter, perfectly like the felloe of a coach-wheel, except that it has neither axis nor radii, and is only joined to the beam, which serves it as an axis by the iron bars. The top of the nut is flat, of a circular figure, and a foot in diameter; and on this is laid the clay which is to be turned and fashioned. The wheel thus disposed is encompassed with four sides of four different pieces of wood fastened on a wooden frame; the hind-piece, which is that on which the workman sits, is made a little inclining towards the wheel; on the fore-piece is placed the prepared earth; on the side-pieces he rests his feet, and these are made inclining to give him more or less room. Having prepared the earth, the potter lays a round piece of it on the circular head of the nut, and, sitting down, turns the wheel with his feet till it has got the proper velocity; then, wetting his hands with water, he presses his fist or his fingers-ends into the middle of the lump, and thus forms the cavity of the vessel, continuing to widen it from the middle; and thus turning the inside into form with one hand, while he proportions the outside with the other, the wheel constantly turning all the while, and he wetting his hands from time to time. When the vessel is too thick, he uses a flat piece of iron, somewhat sharp on the edge, to pare off what is redundant; and when it is finished, it is taken off from the circular head by a wire passed under the vessel.

The potter's lathe is also a kind of wheel, but more simple and slight than the former; its three chief members are an iron beam or axis three feet and a half high, and two feet and a half in diameter, placed horizontally at the top of the beam, and serving to form the vessel upon; and another larger wooden wheel, all of a piece, three inches thick, and two or three feet broad, fastened to the same beam at the bottom, and parallel to the horizon. The beam or axis turns by a pivot at the bottom in an iron stand. The workman gives the motion to the lathe with his feet, by pushing the great wheel alternately with each foot, still giving it a greater or lesser degree of motion as his work requires. They work with the lathe with the same instruments, and after the same manner as with the wheel. The mouldings are formed by holding a piece of wood or iron, cut in the form of the moulding to the vessel, while the wheel is turning round; but the feet and handles are made by themselves, and set on with the hand; and if there is any sculpture in the work, it is usually done in wooden moulds, and stuck on piece by piece on the outside of the vessel. For the glazing of the work, see GLAZING, Vol. 1, page 853.

POUNCE, gum sandarach pounded and sifted very fine, to rub on paper, in order to preserve it from sinking, and to make it more fit to write upon. Pounce is also a little heap of charcoal dust, inclosed in a piece of muslin or some other open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs on paper, silk, &c. placed underneath; which are to be afterwards finished with a pen and ink, a needle, or the like. This kind of pounce is much used by embroiderers, to transfer their patterns upon stuffs; by lace-makers, and sometimes also by engravers.

POUND, a standard-weight, for the proportion and subdivisions of which, see WEIGHT.

POUND also denotes a money of account; so called because the antient pound of silver weighed a pound troy. See MONEY.

POURSUIVANT, or PURSUIVANT, in heraldry, the lowest order of officers at arms. The poursuivants are properly attendants on the heralds, when they marshal public ceremonies. Of these, in England, there were formerly many, but at present there are only four, viz. blue-mantle, rouge-cross, rouge-dragon, and portcullice. In Scotland, there is only one king at arms, who is stiled lion, and has no less than six heralds, and as many poursuivants, and a great many messengers at arms under him.

POWER, in mechanics, denotes any force, whether of a man, a horse, a spring, the wind, water, &c. which being applied to a machine, tends to produce motion.

POWERS, in arithmetic and algebra, are nothing but the products arising from the continual multiplication of a number, or quantity, into itself: thus, 2, 4, 8, 16, 32, &c. are the powers of the number 2; and a, a^2, a^3, a^4, &c. the powers of the quantity a; which operation is called involution.

Powers of the same quantity are multiplied by only adding their exponents, and making their sum the exponent of the product: thus, $a^4 \times a^5 = a^{4+5} = a^9$. Again, the rule for dividing powers of the same quantity, is to subtract the exponents, and make the difference the exponent of the quotient: thus, $\frac{a^6}{a^4} = a^{6-4} = a^2$.

Negative powers, as well as positive, are multiplied by adding, and divided by subtracting their exponents, as above. And, in general, any positive power of a, multiplied by a negative power of a, of an equal exponent, gives unit for the product; for the positive and negative destroy each other, and the product is a^0, which is equal to unit. Likewise, $\frac{a^{-5}}{a^{-2}} = a^{-5+2} = a^{-3} = \frac{1}{a^3}$; and $\frac{a^{-2}}{a^{-5}} = a^{-2+5} = a^3 = \frac{1}{a^{-3}}$. And, in general, any quantity placed in the denominator of a fraction, may be transposed to the numerator, if the sign of its exponent be changed: thus, $\frac{1}{a^3} = a^{-3}$, and $\frac{1}{a^{-3}} = a^3$.

The quantity a^m expresses any power of a, in general; the exponent m being undetermined: and a^{-m} expresses $\frac{1}{a^m}$, or a negative power of a, of an equal exponent: and $a^m \times a^{-m} = a^{m-m} = a^0 = 1$. Again, a^n expresses any other power of a; and $a^m \times a^n = a^{m+n}$, and $\frac{a^m}{a^n} = a^{m-n}$.

To raise any simple quantity to its second, third, or fourth power, is to add its exponent twice, thrice, or four times to itself; so that the second power of any quantity is had by doubling its exponent; and the third, by tripling its exponent; and, in general, the power expressed by m, of any quantity, is had by multiplying the exponent by m: thus the second power, or square of a, is $a^{2\times1} = a^2$; its third power, $a^{3\times1} = a^3$; and the mth power of a, is $a^{m\times1} = a^m$. Also the square of a^4, is $a^{2\times4} = a^8$; the cube of a^4, is $a^{3\times4} = a^{12}$; and the mth power of a^4, is $a^{4\times m}$. The square of abc, is $a^2b^2c^2$; its cube $a^3b^3c^3$; and the mth power, $a^m b^m c^m$. See ALGEBRA.

POWER, in law, is an authority which one man gives to another to act for him; and it is sometimes a reservation which a person makes in a conveyance for himself to do some acts, as to make leases or the like. 2 Lil. Abr. 339. Thus power of attorney, an instrument or deed whereby a person is authorized to act for another, either generally, or in a specific transaction. See AGENT, BROKER, DEED.

POWER *of the county*, contains the aid and attendance of all knights, gentlemen, yeomen, labourers, servants, apprentices, and all others above the age of fifteen years within the county. This the sheriff at any time may raise to assist him in the execution of a precept of restitution. The power of the county is also called the posse comitatus.

POX, or SMALL-POX. See MEDICINE.

PRACTICE, or rules of practice, are certain compendious ways of working the rule of proportion, or golden rule. See ARITHMETIC.

PRÆCIPE, a writ commanding the defendant to do the thing required, or to shew cause why he hath not done it.

PRÆMUNIRE. This punishment is inflicted upon him who denies the king's supremacy the second time; upon him who affirms the authority of the pope, or refuses to take the oath of supremacy; upon such as are seditious talkers of the inheritance of the crown; and upon such as affirm that there is any obligation by any oath, covenant, or engagement whatsoever, to endeavour a change of government either in church or state; or that both or either house or parliament have or has a legislative power without the king, &c.

The judgment in præmunire at the suit of the king, against the defendant being in prison, is, that he shall be out of the king's protection; that his lands and tenements, goods and chattles, shall be forfeited to the king; and that his body shall remain in prison at the king's pleasure; but if the defendant is condemned upon his default of not appearing, whether at the suit of the king or party, the same judgment shall be given as to the being out of the king's protection and the forfeiture; but instead of the clause that the body shall remain in prison, there shall be an award of a capiatur. Co. Lit. 129. Upon an indictment of a præmunire, a peer of the realm shall not be tried by his peers. 12 Co. 92.

PRAGMATIC SANCTION, in the civil law, is defined to be a rescript, or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him on some case of their community. The like answer given to any particular person, is called simply rescript.

The term pragmatic sanction, is chiefly applied to a settlement of Charles VI. emperor of Germany, who, in the year 1722, having no sons, settled his hereditary dominions on his eldest daughter, the archduchess Maria Theresa, which was confirmed by the diet of the empire, and guaranteed by Great Britain, France, the States-General, and most of the powers in Europe.

PRASE, in mineralogy. See QUARTZ.

PRASIUM, in botany, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order verticillatæ. There are four monospermous berries. There are two species.

PREBENDARY, an ecclesiastic who enjoys a prebend. The difference between a prebendary and a canon is, that the former receives his prebend in consideration of his officiating in the church; but the latter merely by his being received into the cathedral or college.

PRECEDENCE, or PRECEDENCY, a place of honour to which a person is entitled: this is either of courtesy or of right. The former is that which is due to age, estate, &c. which is regulated by custom and civility: the latter is settled by authority, and when broken in upon gives an action at law. The following table will exhibit the order of precedency:

A table of precedency of men and women.

The king.
Prince of Wales.
King's sons.
King's brothers.
King's uncles.
King's grandsons.
King's brothers or sisters sons.

Archbishop of Canterbury, lord primate of all England.
Lord high chancellor, or lord keeper.
Archbishop of York, primate of England.
Lord high treasurer. | Being of the degree of barons.
Lord president of the privy council,
Lord privy seal,
Lord high constable.
Earl marshal.
Lord high admiral.
Lord steward of his majesty's household.
Lord chamberlain of his majesty's household.
Dukes according to their patents.
Marquisses according to their patents.
Dukes eldest sons.
Earls according to their patents.
Marquisses eldest sons.
Dukes younger sons.
Viscounts according to their patents.
Earls eldest sons.
Marquisses younger sons.
Bishops of London, Durham, Winchester, and all other bishops according to their seniority of consecration.
Barons according to their patents.
Speaker of the house of commons.
Viscounts eldest sons.
Earls younger sons.
Barons eldest sons.
Knights of the garter.
Privy councillors.
Chancellor of the exchequer.
Chancellor of the duchy of Lancaster.
Lord chief justice of the king's bench.
Master of the rolls.
Lord chief justice of the common pleas.
Lord chief baron of the exchequer.
Judges and barons of the degree of the coife of the said court according to seniority.
Bannerets made by the king himself in person under the royal standard displayed in an army royal, in open war, for the term of their lives and no longer.
Viscounts younger sons.
Barons younger sons.
Baronets.
Bannerets not made by the king himself in person.
Knights of the Bath.
Knights batchelors.
Eldest sons of the younger sons of peers.
Baronets eldest sons.
Knights of the garter's eldest sons.
Bannerets eldest sons.
Knights of the bath's eldest sons.
Knights eldest sons.
Baronets younger sons.
Esquires of the king's body.
Gentlemen of the privy-chamber.
Esquires of the knights of the bath.
Esquires by creation.
Esquires by office.
Younger sons of knights of the garter.
Younger sons of bannerets of both kinds.
Younger sons of knights of the bath.
Younger sons of knights batchelors.
Gentlemen entitled to bear arms.
Clergymen, barristers at law, officers in the navy and army, who are all gentlemen by profession.
Citizens.
Burgesses.

A table of precedency of women.

The queen.
Princess of Wales.
Princesses daughters of the king.
Princesses and duchesses, wives of the king's sons.
Wives of the king's brothers.
Wives of the king's uncles.
Wives of the eldest sons of dukes of the blood royal.
Daughters of dukes of the blood royal.
Wives of the king's brothers or sisters sons.
Duchesses.
Marchionesses.
Wives of the eldest sons of dukes.
Daughters of dukes.
Countesses.
Wives of the eldest sons of marquisses.
Daughters of marquisses.
Wives of the youngest sons of dukes.
Viscountesses.
Wives of the eldest sons of earls.
Daughters of earls.
Wives of the younger sons of marquisses.
Baronesses.
Wives of the eldest sons of viscounts.
Daughters of viscounts.
Wives of the younger sons of earls.
Wives of the eldest sons of barons.
Daughters of barons.
Maids of honour.
Wives of the younger sons of viscounts.
Wives of the younger sons of barons.
Baronetesses.
Wives of knights of the garter.
Wives of bannerets of each kind.
Wives of the knights of the bath.
Wives of knights batchelors.
Wives of the eldest sons of the younger sons of peers.
Wives of the eldest sons of baronets.
Daughters of baronets.
Wives of the eldest sons of knights of the garter.
Daughters of knights of the garter.
Wives of the eldest sons of bannerets.
Daughters of bannerets.
Wives of the eldest sons of knights of the bath.
Daughters of knights of the bath.
Wives of the eldest sons of knights bachelors.
Daughters of knights bachelors.
Wives of the younger sons of baronets.
Daughters of knights.
Wives of the esquires of the king's body.
Wives of the esquires to the knights of the bath.
Wives of esquires by creation.
Wives of esquires by office.
Wives of the younger sons of knights of the garter.
Wives of the younger sons of bannerets.
Wives of the younger sons of knights of the bath.
Wives of the younger sons of knights bachelors.
Wives of gentlemen entitled to bear arms.
Daughters of esquires entitled to bear arms, who are gentlewomen by birth.
Daughters of gentlemen entitled to bear arms, who are gentlewomen by birth.
Wives of clergymen, barristers at law, officers in the navy and army.
Wives of citizens.
Wives of burgesses.

PRECEPT, in law, a command in writing sent by a chief justice, justice of the peace, &c. for bringing a person, record, or other matter, before him.

Precept is also used for the command or incitement by which one man stirs up another to commit felony, theft, &c.

PRECESSION. See EQUINOXES.

PRECIPITATION, a process in chemistry, which is a separation whereby the particles of a body dissolved and suspended in any liquor, are detached from it and fall down to the bottom of the vessel. See CHEMISTRY.

PRECORDIA. See ANATOMY.

PREDIAL TITHES, those which are paid of things arising and growing from the ground only, as corn, hay, fruit of trees, and the like.

PREDICATE, in logic, that part of a proposition which affirms or denies something of the subject: thus, in these propositions, snow is white, ink is not white, whiteness is the predicate which is affirmed of snow, and denied of ink. See PROPOSITION.

It is a celebrated law in predicates, that nothing is esteemed to be absolutely affirmed of another, unless it is affirmed in such a manner as wants nothing either in the subject, predicate, or copula to make it true. This also is a noted property of a predicate, that it contains in some measure its own subject; thus, metal contains gold, silver, copper, &c. of which it is predicated. Every predicate is indeed an attribute; but every attribute is not a predicate; thus, soul, learning, are attributed to man, but not predicated of him.

PREGNANCY, is a plea in stay of execution, when a woman is convicted of a capital crime, alledging that she is with child; in which case, the judge must direct a jury of twelve discreet women to enquire of the fact; and if they bring in their verdict quick with child (for barely with child is not sufficient), execution shall be staid generally, till either she is delivered, or proves by the course of nature, not to have been with child. 4 Black. 395.

PREHNITE. Though this stone had been mentioned by Sage, Romé de Lisle, and other mineralogists, Werner was the first who properly distinguished it from other minerals, and made it a distinct species. The specimen which he examined was brought from the Cape of Good Hope by Colonel Prehn; hence the name prehnite, by which he distinguished it. It was found near Dunbarton by Mr. Grotche; and since that time it has been observed in other parts of Scotland.

It is both amorphous and crystallized. The crystals are in groups, and confused; they seem to be four-sided prisms with dihedral summits. Sometimes they are irregular six-sided plates, and sometimes flat rhomboidal parallelopipeds

Its texture is foliated; fracture uneven; internal lustre pearly; brittle. Specific gravity 2.6 to 2.69. Colour apple green, or greenish grey. Before the blow-pipe it froths more violently than zeolite, and melts into a brown enamel. A specimen of prehnite, analysed by Klaproth, was composed of

43.83	silica
30.33	alumina
18.33	lime
5.66	oxide of iron
1.16	air and water
99.31.	

Whereas Mr. Hassenfratz found in another specimen

50.0 silica
20.4 alumina
23.3 lime
4.9 iron
.9 water
.5 magnesia

100.0.

The mineral known by the name of koupholite is a variety of the prehnite.

PREMISSES, is that part of the beginning of a deed, the office of which is to express the grantor and grantee, and the land or thing granted. 5 Rep. 55. See DEED.

PREMNA, a genus of the didynamia angiospermia class and order. The calyx is two-lobed; corolla four-cleft; berry four-celled; seeds solitary. There are two species, small trees of the East Indies.

PREMUNIRE. See PRÆMUNIRE.

PREANTHES, in botany, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx calyculated; the pappus is simple, and almost sessile; the florets are placed in a single series. There are 19 species, some of them natives of England.

PREPENSE, in law, denotes fore-thought: thus, when a man is slain upon a sudden quarrel, if there was malice prepense formerly between them, it makes it murder.

PREPUSE. See ANATOMY.

PREROGATIVE, is a word of large extent, including all the rights and privileges which by law the king has as chief of the commonwealth, and as intrusted with the execution of the laws. 4 Back. Abr. 149.

All jurisdiction exercised in these kingdoms that are in obedience to our king, is derived from the crown; and the laws, whether of a temporal, ecclesiastical, or military nature, are called his laws; and it is his prerogative to take care of the due execution of them. Hence all judges must derive their authority from the crown, by some commission warranted by law; and must exercise it in a lawful manner, and without any the least deviation from the known and stated forms.

The king, as the fountain of justice, has an undoubted prerogative in erecting officers, and all officers are said to derive their authority mediately, or immediately from him; but though all such officers derive their authority from the crown, and whence the king is termed the universal officer or disposer of justice, yet it has been held, that he has not the office in him to execute it himself, but is only to grant or nominate; nor can the king grant any new powers or privileges to any such officers, but they must execute their offices according to the rules established and prescribed them by law. Co. Lit. 114.

PREROGATIVE COURT, the court wherein all wills are proved, and all administrations taken which belong to the archbishop by his prerogative; that is in case where the deceased had goods of any considerable value out of the diocese wherein he died; and that value is ordinarily 5*l.* except it is otherwise by composition between the said archbishop and some other bishop, as in the diocese of London it is 10*l.* and if any contention grow between two or more, touching any such will or administration, the cause is properly debated and decided in this court. 4 Inst. 335.

PRESBYTERIANS, a sect of protestants, so called from their maintaining that the government of the church appointed in the new testament was by presbyteries; that is, by ministers and ruling elders, associated for its government and discipline.

The presbyterians affirm that there is no order in the church as established by Christ and his apostles, superior to that of presbyters; that all ministers being ambassadors of Christ, are equal by their commission; and that elder or presbyter, and bishop are the same in name and office, for which they alledge, Acts xx. 28, &c. The only difference between them and the church of England, relates to discipline and church government. Their highest assembly is a synod, which may be provincial, national, or œcumenical; and they allow of appeals from inferior to superior assemblies, according to Acts xv. 2, 6, 22, 23. The next assembly is composed of a number of ministers and elders, associated for governing the churches within certain bounds. This authority they found upon Acts xi. 30, Acts xv. 4, 6, &c. The lowest of their assemblies or presbyteries, consists of the minister and elders of a congregation, who have power to cite before them any member, and to admonish, instruct, rebuke, and suspend him from the eucharist. They have also a deacon, whose office is to take care of the poor.

The ordination of their ministers is by prayer, fasting, and imposition of the hands of the presbytery. This is now the discipline of the church of Scotland.

But the appellation presbyterian, is in England appropriated to a large denomination of dissenters, who have no attachment to the Scotch mode of church government any more than to episcopacy among us; and, therefore, to this body of Christians the term presbyterian is improperly applied. English presbyterians adopt the same mode of church government with the independents. See INDEPENDENTS.

PRESCRIPTION, in law, is a right or title acquired by use and time, introduced for assuring the property of effects, in favour of persons who have for a certain time had them in their possession. Prescription has been called a penalty imposed by the laws upon negligence; but the law of prescription does not punish the indolence of proprietors, but only interprets their silence for their consent, presuming that a man who neglects to assert his right for a series of years, gives it up. In the common law, prescription is usually understood of a possession from time immemorial, or beyond the memory of man; but in the civil law, and even in our statute law, there are prescriptions of a much shorter date. The things a person may make title to by prescription are, a fair, market, toll, way, water, rent, common, park, warren, franchise, court-leet, waifs, estrays, &c. There is likewise a prescription against actions and statutes: thus, by the 31 Eliz. c. 1. it is ordained that all actions, &c. that are brought upon statutes, the penalty whereof belongs to the king, shall be brought within two years after the offence is committed, or shall be void. By our statutes also, a judge or clerk convicted of false entering of pleas, &c. may be sued within two years; but the crime of maintenance or embracery, whereby perjury is committed by a jury, must be prosecuted within six days, or otherwise the parties prescribe. See the article LIMITATION.

PRESENTATION, in law, the act of a patron offering his clerk to be instituted in a benefice of his gift, the same being void. All persons that have ability to make a purchase or grant, may also present to vacant benefices in their gift; though where a clergyman is patron of a church, he cannot present himself, but may pray to be admitted by the bishop, and the admission shall be effectual. An infant of any age may also present in his own name; but a presentation by a feme covert must be in the name of both husband and wife. As coparceners make but one patron, they are either to present jointly, or the eldest may present first, and the rest in their turn. Joint-tenants must also join in a presentation; and when a corporation presents, it must be under their common seal. Aliens born and papists cannot present to benefices, which are presented to by the universities; but a popish recusant may grant his patronage to another, who may present where there is no fraud. A patron may revoke his presentation before institution, but not afterwards; and a right of presenting to the next avoidance of a church, whether granted by will or deed, will pass; but a presentation whilst the church is full, is judged void.

PRESENTMENT *of offences*, is that which the grand jury find of their own knowledge, and present to the court, without any bill of indictment laid before them at the suit of the king, as a presentment of a nuisance, a libel, and the like, upon which the officer of the court must afterwards frame an indictment before the party presented can be put to answer it. There are also presentments by justices of the peace, constables, surveyors of the highways, church-wardens, &c.

PRESIDENT, an officer created or elected to preside over a company, in contradistinction to the other members, who are called residents.

The lord president of the council is the fourth great officer of the crown, as antient as king John, when he was stiled conciliarius capitalis. His office is to attend on the king, propose business at the council table, and report the transactions there to the king.

The lord president of the court of session in Scotland, is the first of the fifteen lords who presides in that august assembly, which is the supreme court of justice in that kingdom.

PRESS, in the mechanic arts, a machine made of iron or wood, serving to squeeze or compress any body very close. The ordinary presses consists of six members, or pieces, viz. two flat smooth planks, between which the things to be pressed are laid; two screws or worms, fastened to the lower plank, and passing through two holes in the upper; and two nuts, in form of an S, serving to drive the upper plank, which is moveable, against the lower, which is stable, and without motion.

PRESS *used by inlayers*, resembles the joiner's press, except that the pieces of wood are thicker, and that only one of them is moveable; the other, which is in form of a tressel, being sustained by two legs or pillars, jointed into it at each end. This press serves them for sawing and cleaving the pieces of wood required in marquetry or inlaid work.

PRESS, *founder's*, is a strong square frame, consisting of four pieces of wood firmly joined together with tenons, &c. This press is of various sizes, according to the sizes of the moulds; two of them are required to each mould, at the two extremes whereof they are placed; so as that, by driving wooden wedges between the mould and the sides of the presses, the two parts of the mould wherein the metal is to be run may be pressed close together.

PRESS, *printing*. See PRINTING-PRESS.

PRESS, *rolling*, is a machine used for the taking off prints from copper plates. It is much less complete than that of the letter-printers. See its description and use under the article *Rolling-press* PRINTING.

PRESS, *in coining*, is one of the machines used in striking of money, differing from the balance in that it has only one iron bar to give it motion, and press the moulds or coins: it is not charged with lead at its extremes, nor drawn by cordage. See COINING.

Binder's cutting-PRESS, is a machine used equally by bookbinders, stationers, and pasteboard-makers; consisting of two large pieces of wood, in form of cheeks, connected by two strong wooden screws, which, being turned by an iron bar, draw together, or set asunder, the cheeks, as much as is necessary for the putting in the books or paper to be cut. The cheeks are placed lengthwise on a wooden stand, in the form of a chest, into which the cuttings fall. Aside of the cheeks are two pieces of wood, of the same length with the screws, serving to direct the cheeks, and prevent their opening unequally. Upon the cheeks the plough moves, to which the cutting-knife is fastened by a screw; which has its key, to dismount it on occasion to be sharpened.

The plough consists of several parts; among the rest a wooden screw or worm, which, catching within the nuts of the two feet that sustain it on the cheeks, brings the knife to the book or paper which is fastened in the press between two boards. This screw, which is pretty long, has two directories, which resemble those of the screws of the press. To make the plough slide square and even on the cheeks, so that the knife may make an equal paring, that foot of the plough where the knife is not fixed, slides in a kind of groove, fastened along one of the cheeks. Lastly, the knife is a piece of steel, six or seven inches long, flat, thin, and sharp, terminating at one end in a point, like that of a sword, and at the other in a square form, which serves to fasten it to the plough. See BOOKBINDING.

As the long knives used by us in the cutting of books or paper are apt to jump in the cutting thick books, the Dutch are said to use circular knives, with an edge all round, which not only cut more steadily, but last longer without grinding.

PRESS, *in the woollen manufactory*, is a large wooden machine, serving to press cloths, serges, rateens, &c. thereby to render them smooth and even, and to give them a gloss. This machine consists of several members; the principal whereof are the cheeks, the nut, and the worm or screw, accompanied with its bar, which serves to turn it round, and make it descend perpendicularly on the middle of a thick wooden plank, under which the stuffs to be pressed are placed. The calender is also a kind of press, serving to press or calender linens, silks, &c.

PRESSES used for expressing of liquors are of various kinds; some, in most respects, the same with the common presses, excepting that the under plank is perforated with a great number of holes, to let the juice expressed run through into a tub or receiver underneath.

Plate, Presses, fig. 1, is a simple packing press, described by M. Buschendorf, in Les Annales des Arts. ABD is a strong frame of wood; through the upper bar D a strong iron rack E, similar to a saw, slides a small click *e*, pushed by a spring, prevents it rising after the lever F has pressed it down: the lower end of this rack has the bed of the press K fixed to it, under which the goods G to be pressed are put. The lever F has a mortise through it, to admit the rack E; and a click *f*, which takes into its teeth the lever, moves round a bolt *g*, as a centre, which can be put through any of the holes in the beam, according to the quantity of the goods to be pressed. The machine operates as follows. When the lever F is lifted up, its click *f* slips over the sloping side of the teeth, and when it is pulled down, the click takes hold of the teeth and draws the rack down with it another tooth: the click *e* then holds it, while the lever is raised to take another tooth as before. The only objection to this simple press is a want of power for pressing many articles, and that the teeth of the rack could not be made fine enough for a man to press down a whole tooth without resting. To remedy the first inconvenience, it has occurred to us that a bolt *h* might be put through two of the beams, and the end of a common handspike H put under it. This handspike might be connected with F by an endless chain put over both: this chain might have a hook at the end, so as to shorten or lengthen it by hooking it into another link, as occasion required. For the second inconvenience a plate of iron *i*, with teeth in it, might be fastened to the lever F, and a long click I, connected with the frame, might fall into them, so as to prevent the lever rising. By this means each tooth of the rack may be divided into four or five parts; and when the click *e* takes hold of a new tooth, the long click I may be lifted up, and the lever raised. As before, the click might be hooked up when the press I is used as above described: the chain or handspike may be taken away, and replaced in a very short time.

Fig. 2. is a screw-press, used for expressing some kinds of oil; the frame ADB is formed of one piece of cast-iron, the upper piece has a brass nut fixed in it, through which the screw E works; the screw has holes through its lower end, to put in a long iron lever F, by which the screw is turned. The substance from which the oil is to be pressed is tied up in horse-hair bags, and laid under the bed of the press G, with a warm iron plate between each bag; the screw is then turned by men, as long as they can move it: a rope is then hooked to the end of the lever, and the power of a windlass or capstan is used to assist the lever: the oil weeps out of the bags, and runs down through a spout into the reservoir H, placed to raise it.

Fig. 3. is a representation of the hydrostatic press for which Mr. Bramah took out a patent in 1796. The frame of this is like a common press; the bed A is fastened to the piston B of a stout brass barrel D, the lower end of which communicates by a pipe E, with a forcing pump within the cylindric vessel F; the piston *f f* of this is cut hollow, and has the connecting rod *g* jointed within side of it. The lever *b*, which works the pump, is jointed to the lower end of this rod, so that the circular motion of the lever is allowed by the connecting rod *g* moving in or out of the hollow in the piston rod; and the parallelism of the piston is preserved by a collar H.

Fig 4. explains the construction of the pump within the cistern F; I is the barrel of brass, this has the piece J screwed into it lower, and this piece J is screwed into the end of the pipe E, and contains within it a valve opening downwards. To the part L of the barrel, the piece K containing a valve opening inwards is screwed; this is open to the water, oil, &c. contained in the cistern F, when the lever G is raised, the barrel fills with water through the valve K, and when it is pushed down, the valve K shuts, J opens, and the water is forced through the pipes E into the large barrel D, and by pushing out its piston B, presses the goods laid upon the bed A of the press. When the goods are sufficiently pressed, the lever G is pushed down, and the lower end of the piston opens the valves JK, and the dettent *k* pushes towards the piston, opens the valves K, which allows the water to pass back into the reservoir, the bed of the press falls down, the valves are composed of a small brass cone, fig. 4. which exactly fits its seat, and is kept in its place by a wire fastened to it; this wire is cut flat on one side to allow the water to pass through when the valve is open, and a small spiral spring closes it.

PRESS *used by joiners*, to keep close the pieces they have glued, especially pannels, &c. of wainscot, is very simple, consisting of four members, viz. two screws, and two pieces of wood, four or five inches square, and two or three feet long; whereof the holes at the two ends serve for nuts to the screws.

PRESSING, in the manufactures, is the violently squeezing a cloth, stuff, &c. to render it smooth and glossy There are two methods of pressing, viz. cold or hot. As to the former, or cold-pressing, after the stuff has been scoured, fulled, and shorn, it is folded square in equal plaits, and a skin of vellum, or pasteboard, put between each plait. Over the whole is laid a square wooden plank, and so put into the press, which is screwed down tight by means of a lever. After it has lain a sufficient time in the press, they take it out, removing the pasteboards, and lay it up to keep. Some only lay the stuff on a firm table, after plaiting and pasteboarding, cover the whole with a wooden plank, and load it with a proper weight.

The method of pressing hot is this: when the stuff has received the above preparations, it is sprinkled a little with water, sometimes gum-water, then plaited equally, and between each two plaits are put leaves of pasteboard; and between every sixth or seventh plait, as well as over the whole, an iron or brass-plate well heated in a kind of furnace. This done, it is laid upon the press, and forcibly screwed down. Under this press are laid five, six, &c. pieces at the same time, all furnished with their pasteboards and iron-plates. When the plates are well cold, the stuffs are taken out and stitched a little together to keep them in the plaits. This manner of pressing was only invented to cover the defects of the stuffs; and accordingly it has been frequently prohibited.

PREVARICATION, in the civil law, is where the informer colludes with the defendants, and so makes only a sham prosecution.

PRICKING, in the sea-language, is to make a point on the plan or chart, near about where the ship then is, or is to be at such a time, in order to find the course they are to steer.

PRIMÆ VIÆ, among physicians, denote the whole alimentary duct; including the oesophagus, stomach, and intestines, with their appendages.

PRIMATES, the first order of mammalia in the Linnean system; they are distinguished by fore-teeth cutting, upper four parallel (except in some species of bats, which have two or none); tusks solitary, that is, one on each side, in each jaw; teats two, pectoral; feet two, are hands; nails, usually flattened, oval; food fruits, except a few that use animal food. There are four genera, viz. homo, lemur, simia, and vespertilio.

PRIMING, or *prime of a gun*, is the gunpowder put into the pan or touch-hole of a piece, to give it fire thereby; and this is the last thing done in charging.

For pieces of ordnance they have a pointed iron-rod, to pierce the cartridge through the touch-hole, called primer or priming-iron.

PRIMOGENITURE, the right of first-born. This right seems to be an unjust prerogative, and contrary to the natural right; for since it is birth alone gives children a title to the paternal succession, the chance of primogeniture should not throw any inequality among them.

It was not till the race of Hugh Capet, that the prerogative of succession to the crown was appropriated to the first-born. By the antient custom of gavel-kind, still preserved in some parts of our island, and we believe throughout the United States of America, primogeniture is of no account, the paternal estate being equally shared among the sons. See Gavel-kind.

PRIMULA, the *primrose*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 21st order, preciæ. The involucrum lies under a simple umbel; the tube of the corolla cylindrical, with the mouth or limb patulous. This genus, including also the polyanthus and auricula, furnishes an excellent collection of low, fibrous-rooted, herbaceous, flowery perennials, extending to 20 species, of which the most remarkable are:

1. The primula vulgaris, or spring primrose, has thick and very fibrous roots, crowned by a cluster of large oblong indented rough leaves, and numerous flower-stalks, from about three or four, to five or six inches high, each terminated commonly by one flower. The varieties are, common yellow-flowered primrose of the woods, white primrose, paper white, red, double red, double yellow, and double white. All these flower abundantly in March and April, and continue for a month or six weeks. 2. Primula officinalis. The paigle or cowslip has very thick fibrous roots, crowned by a cluster of oblong, indented, round leaves, and upright, firm flower stalks five or six inches high, terminated each by a cluster of small flowers. The varieties are, common single yellow cowslip of the meadows, double yellow cowslip, scarlet cowslip, ho e and hose-cowslip; one flower growing out of the bosom of another, the lowermost serving as a calyx, all of which varieties have the flower-stalks crowned by many flowers in branches. They flower in April and May, continuing in succession a month or six weeks. 3. Primula elatis, the great cowslip, oxcip. The polyanthus, so long and so much cultivated in English gardens, is a variety of these. The polyanthus is one of the noted prize flowers among the florists, many of whom are remarkably industrious in raising a considerable variety of different sorts, as well as in using every art to blow them with all requisite perfection; for among the virtuosi, a polyanthus must possess several peculiar properties in order to be admitted in their collections. The chief properties required in a florist's polyanthus, are: 1. The stem or flower-stalk shall be upright, moderately tall, with strength in proportion, and crowned by a good regular bunch of flowers on short pedicles, strong enough to support them nearly in an upright position. 2. The florets of each branch should be equally large, spreading open flat, with the colours exquisite, and the stripes and variegations lively and regular. 3. The eye in the centre of each floret should be large, regular, and bright; and the antheræ, by the florists called the thrum, should rise high enough to cover the mouth of the tube or hollow part in the middle of the florets, and render them what they call thrum-eyed; but when the style elevates the stigma above the antheræ, the eye of the tube generally appears hollow, showing the stigma in the middle, like the head of a pin, and is rejected as an incomplete flower, though its other properties should be ever so perfect. This pin-eyed polyanthus, however, though rejected by the florists, is the flower in its most perfect state, and great numbers of them are of as beautiful forms and colours as the thrum-eyed varieties.

4. Primula auricula has a thick fibrous root, crowned by a cluster of oblong, fleshy, broad, serrated, smooth leaves, resembling the shape of a bear's ear; and amidst them upright flower-stalks from about three or four to six or eight inches high, terminated by an umbellate cluster of beautiful flowers, of many different colours in the varieties. All of these have a circular eye in the middle of each flower, and of which there are different colours; whence the auriculas are distinguished into yellow-eyed, white-eyed, &c. The petals of most of the kinds are powdered with an exceeding fine farina or mealy powder, which contributes greatly to the beauty of the flower. They all flower in April or May, continuing a month or six weeks in beauty, and ripening plenty of seeds in June.

All the varieties of the common spring primrose multiply so fast by the roots, that it is scarcely worth while to raise them from seeds. However, though many single kinds may be raised from seed, yet parting the roots is the only method by which the double kind can be preserved; and the same thing is to be observed of all the rest.

PRINCE's METAL, a mixture of copper and zinc, in imitation of gold. See Zinc.

PRINCIPAL POINT. See Perspective.

PRINCIPLE EXTRACTIVE. See Plants, *physiology of*.

PRINOS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is sexfid; the corolla monopetalous, and rotaceous; the belly hexaspermous. There are seven species, natives of the West Indies.

PRINT, the impression taken from a copper-plate. See Printing.

A print may be taken off, so as that the outlines and principal strokes may be exactly copied for engraving, in the following manner. If the print is not above a year or two old, the paper need only be well moistened with water, as for printing, but if it is more antient, it should be laid to soak all night in water, and afterwards hung in the air till it becomes dry enough for the press. The paper thus prepared is to be laid with its printed side next to the plate, thinly cased over with white wax; and is thus to be communicated to the rolling-press, whereby an impression of the cut will be gained.

PRINTING, the art of taking impressions from characters or figures moveable, or immoveable, on paper, linnen, silk, &c. There are three kinds of printing, the one from moveable letters for books; the other from copper-plates for pictures; and the last from blocks, in which the representation of birds, flowers, &c. are cut for printing calicoes, linnens, &c. the first, called common press-printing, the second rolling press-printing, and the last calico, &c. printing. The principal difference between the three consists in this, that the first is cast in relievo in distinct pieces, the second engraven in creux, and the third cut in relievo, and generally stamped, by placing the block upon the materials to be printed and striking upon the back of it. See Calico Printing.

Printing, *progress of.* Who the first inventors of the European method of printing books were, in what city, and what year it was set on foot, are questions long disputed among the learned. In effect, as the Grecian cities contended for the birth of Homer, so do the German for that of printing. Mentz, Haerlem, and Strasburg, are the warmest on this point of honour, and these are left in possession of the question, which is not yet decided: though it must be owned that Mentz has always had the majority of voices. John Guttemburg, and John Fust of Mentz, John Mentel of Strasburg, and L. John Koster of Haerlem, are the persons to whom this honour is severally ascribed, by their respective countrymen; and they have all their advocates among the learned. However, their first essays were made on wooden blocks, after the Chinese manner. The book at Haerlem, the vocabulary called Catholicon, and the pieces in the Bodleian library, and that of Bennet college, are all performed in this way; and the impression appears to have been only given on one side of the leaves; after which the two blank sides were pasted together. But they soon found the inconveciences of this method, and therefore an improvement was suggested, which was, by making single letters distinct from one another, and these being first done in wood, gave room for a second improvement, which was making them of metal; and in order to that, forming moulds, matrices, &c. for casting them. See TYPE.

From this ingenious contrivance we ought to date the origin of the present art of printing, contradistinguished from the method practised by the Chinese. And of this Schoeffer, or Scheffer, first servant, and afterwards partner and son-in-law of Fust, at Mentz, above-mentioned, is generally allowed to be the inventor; so that he may properly be reckoned the first printer, and the Bible which was printed with moveable letters in 1450, the first printed book; the next was Augustine de Civitate Dei, then Tully's Offices, printed about the year 1461. In these books they left the places of the initial letters blank, and gave them to the illuminers to have them ornamented and painted in gold and azure, in order to render the work more beautiful, and, as some think, to make their books pass for manuscripts. Thus at present, in some curious works, the initial letter at the beginning of a book or chapter, is sometimes left out, and a space is left for its being afterwards printed with various ornaments from a copper-plate.

Some authors tell us, that Fust carrying a parcel of Bibles with him to Paris, and offering them to sale as manuscripts; the French, upon considering the number of books, and their exact conformity to each other, even to a point, and that it was impossible for the best book-writers to be so exact, concluded there was witchcraft in the case, and by their actually indicting him as a conjurer, or threatening to do so, extorted from him the secret; and hence the origin of the popular story of Dr. Faustus.

From Mentz, the art of printing soon spread itself throughout a good part of Europe; Haerlem and Strasburg had it very early; from Haerlem it passed to Rome in 1467; and into England in 1468, by means of Thos. Bourchier, archbishop of Canterbury, who sent W. Turner, master of the robes, and W. Caxton, merchant, to Haerlem to learn the art. These privately prevailing with Corseilles, an under-workman, to come over, a press was set up at Oxford, and an edition of Ruffinus on the Creed was printed the same year in octavo. From Oxford, Caxton brought it to London about the year 1470, and the same year it was carried to Paris. Hitherto there had been nothing printed but in Latin, and the vulgar tongues; and this first in Roman characters, then in Gothic, and at last in Italic; but in 1480, the Italians cast a set of Greek types, and they have also the honour of the first Hebrew editions, which were printed about the same time with the Greek. Towards the end of the sixteenth century there appeared various editions of books in Syriac, Arabic, Persian, Armenian, Coptic, or Egyptian characters, some to gratify the curiosity of the learned, and others for the use of the Christians of the Levant. Out of Europe, the art of printing has been carried into the three other parts of the world.

PRINTING, *method of:* the printing-letters, or types as they are sometimes called, are described, as well as the method of forming and casting them, under the article TYPE.

The workmen employed in the art of printing are of two kinds; compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author; and pressmen, who apply ink upon the same, and take off the impression. The types being cast, the compositor distributes each kind by itself among the divisions of two wooden frames, an upper and an under one, called cases, each of which is divided into little cells or boxes. Those of the upper case are in number ninety-eight; these are all of the same size, and in them are disposed the capitals, small capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower case, which are fifty-four, are placed the small letters with the points, spaces, &c. The boxes are here of different sizes, the largest being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letters oftenest wanted, are nearest the compositor's hand. Each case is placed a little aslope, that the compositor may the more easily reach the upper boxes. The instrument in which the letters are set is called a composing-stick, see Plate Miscel. fig. 193; which consists of a long and narrow plate of brass or iron, &c. *c*, on the right side of which arises a ledge *bb*, which runs the whole length of the plate, and serves to sustain the letters, the sides of which are to rest against it: along this ledge is a row of holes, which serve for introducing the screw *a* in order to lengthen or shorten the extent of the line, by moving the sliders *bc* farther from, or nearer to, the short ledge at the end *d*. Where marginal notes are required in a work, the two sliding-pieces *bc* are opened to a proper distance from each other; in such a manner as that while the distance between *b* and *c* forms the length of the line in the text, the distance between the two sliding-pieces forms the length of the lines for the notes on the side of the page. Before the compositor proceeds to compose, he puts a rule, or thin slip of brass plate, cut to the length of the line, and of the same height as the letter, in the composing stick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his stick in his left hand, his thumb being over the slider *c*; with the right he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by pressing them to the end of the slider *c*, the other hand being constantly employed in setting in more letters: the whole being performed with a degree of expedition and address not easy to be imagined.

A line being thus composed, if it ends with a word or syllable, and exactly fills the measure, there needs no farther care; otherwise more spaces are to be put in, or else the distances lessened between the several words, in order to make the measure quite full; so that every line may end even. The spaces here used are pieces of metal exactly shaped like the shanks of the letters; these are of various thicknesses, and serve to support the letters, and to preserve a proper distance between the words; but not reaching so high as the letters, they make no impression when the work is printed. The first line being thus finished, the compositor proceeds to the next; in order to which he moves the brass rule from behind the former, and places it before it, and thus composes another line against it, after the same manner as before; going on thus till his stick is full, when he empties all the lines contained in it into the galley; which is a frame formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom. The compositor then fills and empties his composing-stick as before, till a complete page is formed; when he ties it up with a cord or packthread, and setting it by, proceeds to the next, till the number of pages to be contained in a sheet is completed; which done, he carries them to the imposing-stone, there to be ranged in order, and fastened together in a frame called a chase, and this is termed imposing. The chase is a rectangular iron frame, of different dimensions according to the size of the paper to be printed; having two cross pieces of the same metal, called a long and short cross, mortised at each end, so as to be taken out occasionally. By the different situation of these crosses the chase is fitted for different volumes; for quartos and octavos, one traverses the middle lengthwise, the other broadwise, so as to intersect each other in the centre; for twelves and twenty-fours the short cross is shifted nearer to one end of the chase; for folios the long cross is left entirely out, and the short one left in the middle; and for broadsides both crosses are set aside. To dress the chase, or range and fix the pages therein, the compositor makes use of a set of furniture, consisting of slips of wood of different dimensions, and about half an inch high that they may be lower than the letters: some of these are placed at the top of the pages, and called head-sticks; others between them to form the inner margin; others on the sides of the crosses to form the outer margin, where the paper is to be doubled; and others in the form of wedges to the sides and bottom of the pages. Thus all the pages being placed at their proper distances, and secured from being injured by the chase and furniture placed about them, they are all untied, and fastened together by driving small pieces of wood called quoins, cut in the wedge-form, up between the slanting side of the foot and side-sticks and the chase, by means of a piece of hard wood and a mallet; and all being thus bound fast together, so that none of the letters will fall out, it is ready to be committed to the pressman. In this condition the work is called a form; and as there are two of these forms required for every sheet, when both sides are to be printed, it is necessary that the distances between the pages in each form should be placed with such exactness, that the impression of the pages in one form shall fall exactly on the back of the pages of the other, which is called register.

As it is impossible but that there must be some mistakes in the work, either through the oversight of the compositor, or by the casual transposition of letters in the case, a sheet is printed off, which is called a proof, and given to the corrector, who reading it over, and rectifying it by the copy, by making the alterations in the margin, it is delivered back to the compositor to be corrected. For the characters used in correcting a sheet for the compositor, see CORRECTION.

The compositor then unlocking the form upon the correcting-stone, by loosening the quoins or wedges which bound the letters together, rectifies the mistakes by picking out the faulty or wrong letters with a slender sharp-pointed steel bodkin, and puts others into their places; but when there are considerable alterations, and particularly where insertions or omissions are to be made, he is under a necessity of over-running. Thus, if one or more words to be inserted in a line cannot be got in by changing the spaces for lesser ones, part of the line must be put back into the close of the preceding one, or forward into the beginning of the subsequent one, and this continued till the words are got in. After this another proof is made, sent to the author, and corrected as before: and, lastly, there is another proof, called a revise, which is made in order to see whether all the mistakes marked in the last proof are corrected.

The pressman's business is, to work off the forms thus prepared and corrected by the compositor; in doing which there are four things required, paper, ink, balls, and a press. To prepare the paper for use, it is to be first wetted by dipping several sheets together in water; these are afterwards laid in a heap over each other; and to make them take the water equally, they are all pressed close down with a weight at the top. The ink is made of oil and lamp-black, for the manner of preparing which see INK.

The balls by which the ink is applied on the forms, are a kind of wooden funnels with handles, the cavities of which are filled with wool or hair; also a piece of alum-leather or pelt is nailed over the cavity, and made extremely soft by soaking in urine, and by being well rubbed. One of these the pressman takes in each hand, and applying one of them to the ink-block, dabs and works them together to distribute the ink equally; and then blackens the form which is placed on the press, by beating with the balls upon the face of the letter.

The printing-press represented in the Plate, fig. 194, is a very curious, though complex machine; the body consists of two strong cheeks *aa*, placed perpendicularly, and joined together by four cross-pieces; the cap *b*; the head *c*, which is moveable, being partly sustained by two iron pins or long bolts, that pass the cap; the till or shelf *dd*, by which the spindle and its apparatus are kept in their proper position; and the winter *e*, which bears the carriage, and sustains the effort of the press beneath. The spindle *f* is an upright piece of iron pointed with steel, having a male screw which goes into the female one in the head about four inches. Through the eye *g* of this spindle is fastened the bar *k*, by which the pressman makes the impression. The spindle passes through a hole in the middle of the till; and its point works into a brass pan or nut, supplied with oil, which is fixed to an iron plate let into the top of the platten. The body of the spindle is sustained in the centre of an open frame of polished iron, 1, 1, 2, 2, 3, 3, fixed to it in such a manner, as, without obstructing its free play, to keep it in a steady direction, and at the same time to serve for suspending the platten. This frame consists of two parts; the upper, called the garter, 1, 1; and the under, called the crane, 2, 2. These are connected together by two short legs or bolts, 3, 3, which being fixed below in the two ends of the crane, pass upwards through two holes in the till, and are received at top into two eyes at the ends of the garter, where they are secured by screws. The carriage *ll* is placed a foot below the platten, having its fore part supported by a prop called the fore stay, while the other rests on the winter. On this carriage, which sustains the plank, are nailed two long iron bars or ribs; and on the plank are nailed short pieces of iron or steel, called cramp-irons, equally tempered with the ribs, and which slide upon them when the plank is turned in or out. Under the carriage is fixed a long piece of iron called the spit, with a double wheel in the middle, round which leather girths are fastened, nailed to each end of the plank; and to the outside of the spit is fixed a rounce *m*, or handle, to turn round the wheel. Upon the plank is a square frame or coffin, in which is inclosed a polished stone, on which the form *n* is laid; at the end of the coffin are three frames, viz. the two tympans and frisket; the tympans *o* are square, and made of three slips of very thin wood, and at the top a piece of iron still thinner; that called the outer tympan is fastened with hinges to the coffin; they are both covered with parchment; and between the two are placed blankets, which are necessary to take off the impression of the letters upon the paper. The frisket *p* is a square frame of thin iron, fastened with hinges to the tympan: it is covered with paper cut in the necessary places, that the sheet which is put between the frisket and the great or outward tympan may receive the ink, and that nothing may hurt the margins. To regulate the margins, a sheet of paper is fastened upon this tympan, which is called the tympan-sheet; and on each side is fixed an iron point, which makes two holes in the sheet, which is to be placed on the same points when the impression is to be made on the other side. In preparing the press for working, the parchment which covers the outer tympan is wetted till it is very soft, in order to render the impression more equable; the blankets are then put in, and secured from slipping by the inner tympan: then while one pressman is beating the letter with the balls *q*, covered with ink taken from the ink-block, the other man places a sheet of white paper on the tympan-sheet, turns down the frisket upon it to keep the paper clean and prevent its slipping, then bringing the tympans upon the form, and turning the rounce, he brings the form with the stone, &c. weighing about 300lbs. weight, under the platten; pulls with the bar, by which means the platten presses the blankets and paper close upon the letter, whereby half the form is printed; then easing the bar, he draws the form still forward, gives a second pull; and letting go the bar, turns back the form, takes up the tympans and frisket, takes out the printed sheet, and lays on a fresh one; and this is repeated till he has taken off the impression upon the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the press, and worked off in the same manner. See STEREOTYPE.

PRINTING, *Chinese*, is performed from wooden planks or blocks, cut like those used in printing of callico, paper, cards, &c.

PRINTING, *rolling-press*, is employed in taking off prints or impressions from copper-plates engraved, etched, or scraped, as in mezzotintos. See ENGRAVING. This art is said to have been as antient as the year 1540; and to owe its origin to Finiguerra, a Florentine goldsmith, who pouring some melted brimstone on an engraved plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur: upon this he attempted to do the same on silver plates with wet paper, by rolling it smoothly with a roller, and this succeeded: but this art was not employed in England till the reign of king James I., when it was brought from Antwerp by Speed. The form of the rolling-press, the composition of the ink used in it, and the manner of applying both in taking off prints, are as follow:

The rolling-press AL, Plate 195, may be divided into two parts, the body and carriage; the body consists of two wooden cheeks PP, placed perpendicularly on a stand or foot LM, which sustains the whole press. From the foot likewise rise four other perpendicular pieces *c*, *c*, *c*, *c*, joined by other cross or horizontal ones *d*, *d*, *d*, which serve to sustain a smooth even plank or table HIK, about four feet and a half long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DEFG, about six inches in diameter, borne up at each end by the cheeks; whose ends, which are lessened to about two inches diameter, and called trunnions, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate their motion. Lastly, to one of the trunnions of the upper roller is fastened a cross, consisting of two levers AB, or pieces of wood, traversing each other: the arms of which cross serve instead of the bar or handle of the letter-press, by turning the upper roller; and when the plank is between the two rollers, giving the same motion to the under one, by drawing the plank forward and backward.

The ink used for copper-plates is a composition made of the stones of peaches and apricots, the bones of sheep, and ivory, all well burnt, and called Frankfort black, mixed with nut-oil that has been well boiled, and ground together on a marble in the same manner as painters do their colours.

The method of printing from copper-plates is as follows: They take a small quantity of this ink on a rubber made of linen rags strongly bound about each other, and with it smear the whole face of the plate as it lies on a grate over a charcoal fire. The plate being sufficiently inked, they first wipe it over with a foul rag, then with the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they rub it from time to time in whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman consists. The plate thus prepared, is laid on the plank of the press; over the plate is laid the paper, first well moistened to receive the impression; and over the paper two or three folds of flannel. Things thus disposed, the arms of the cross are pulled, and by that means the plate with its furniture is passed through between the collars; which pinching very strongly, yet equally, press the moistened paper into the strokes of the engraving, whence it absorbs the ink

PRISM, in geometry, an oblong solid, contained under more than four planes, whose bases are equal, parallel, and alike situated. See GEOMETRY.

PRISM, in dioptrics. See OPTICS.

PRISON, a gaol, or place of confinement. See GAOL. Lord Coke observes, that a prison is only a place of safe custody, salva custodia, not a place of punishment. Any place where a person is confined may be said to be a prison: and when a process is issued against one, he must, when arrested thereon, either be committed to prison, or be bound in a recognizance with sureties, or else give bail, according to the nature of the case, to appear at a certain day in court, there to make answer to what is alleged against him. When a person is taken and sent to prison in a civil case, he may be released by the plaintiff in the suit; but if it is for treason or felony, he may not regularly be discharged until he is indicted of the fact and acquitted.

The good policy of imprisonment for debt has been frequently called in question (probably by those who were most in danger of suffering from it). We are of opinion, however, that it is in the whole productive of salutary consequences in a state, and the terror of a gaol is is many cases an useful moral restraint. The following paper, however, set forth by the laudable society for the discharge and relief of persons imprisoned for small debts, will excite various reflections in different readers; and without any comment we submit it as a curious document to the statesman, or political arithmetician, as throwing some light on the manners and character of the age.

A summary view of the money annually expended by the society for the discharge and relief of persons imprisoned for small debts, Craven-street, Strand, from the institution in 1772, to the 31st of March, 1804.

1772 to	No. of debtors discharged and relieved.	Expended. £.	s.	d.
1774	1772 for the sum of	4622	17	1

20,906 debtors, who had 12,546 wives and 35,699 children } 69,115 persons immediately benefited for 54781*l.* 3*s.* 5½*d.*

The average for the debts of the above 20,905 debtors is 2*l.* 12*s.* 4½*d.* each, and for each individual relieved 15*s.* 1*d.*

PRISTIS, or saw-fish, a genus of fishes of the order chondropterigii: the generic character is, snout long, flat, spinous down the edges, spiracles lateral; body oblong, roundish, covered with a rough, coriaceous skin; mouth beneath; nostrils before the mouth, half-covered with a membranaceous flap; behind the eyes two oval orifices; ventral fins approximate. There are five species:

1. Pristis antiquorum. The head is rather flat at top; the eyes large, with yellow irides; behind each is a hole, which some have supposed may lead to an organ of hearing. The mouth is well furnished with teeth, but they are blunt, serving rather to bruise its prey than to divide it by cutting. Before the mouth are two foramina, supposed to be the nostrils. The rostrum, beak, or snout, is in general about one-third of the total length of the fish, and contains in some eighteen, in others twenty-three or twenty-four, spines on each side; these are very stout, much thicker at the back part, and channelled, inclining to an edge forwards. The fins are seven in number, viz. two dorsal, placed at some distance from each other; two pectoral, taking rise just behind the breathing-holes, which are five in number; two ventral, situated almost underneath the first dorsal; and lastly, the caudal, occupying the tail both above and beneath, but longest on the upper part. The general colour of the body is a dull grey, or brownish, growing paler as it approaches the belly, where it is nearly white. 2. Pectinatus, which, with the former species, grows to the largest size of any that have yet come under the inspection of the naturalist, some specimens measuring 15 feet in length. The pectinatus differs from the pristis antiquorum, in having the snout more narrow in proportion at the base, and the whole of it more slender in all its parts; whereas the first is very broad at the base, and tapers considerably from thence to the point. The spines on each side are longer and more slender, and vary from twenty-five to thirty-four in the different specimens: we have indeed been informed of one which contained no less than thirty-six spines on each side of the snout; but we must confess that we have never been fortunate enough to have seen such a specimen. 3. Cuspidatus, of which we have only seen two specimens, the one about a foot and a half in length, and the other more than two feet and a half. In both of these were twenty-eight spines on each side; but the distinguishing feature is in the spines themselves being particularly flat and broad, and shaped at the point more like the lancet used by surgeons in bleeding, than any other figure. We believe that no other author has hitherto taken notice of this species. 4. Microdon, of which the total length is twenty-eight inches, the snout occupying ten; from the base of this to that of the pectoral fins four inches; between the pectoral and ventral fins six. The two dorsal fins occupy nearly the same proportions in respect to each other; but the hinder one is the smallest, and all of them are greatly hollowed out at the back part, much more so than in the two first species. The snout differs from that of every other, in several particulars: it is longer in proportion, being more than one-third of the whole fish. The spines do not stand out from the sides more than a quarter of an inch, and from this circumstance seem far less capable of doing injury than any other species yet known. 5. Cirratus, of which we have only met with one specimen, which was brought from Port Jackson in New Holland. It is a male, and the total length about 40 inches; the snout, from the tip of it to the eye, eleven: the spines widely different from any of the others; they are indeed placed, as usual, on the edge, but are continued on each side even beyond the eyes. The longer ones are slender, sharp, somewhat bent, and about twenty in number; and between these are others not half the length of the primal ones, between some three or four, between others as far as six; and in general the middle one of these smaller series is the longest: beside these a series of minute ones may be perceived beneath, at the very edge. In the snout likewise another singularity occurs:—about the middle of it, on each side, near the edge, arises a flexible, ligamentous cord, about three inches and a half in length, appearing not unlike the beards at the mouth of some of the gadus or cod genus, and no doubt as pliant in the recent state. The colour of the fish is a pale brown; the breathing apertures four in number; the mouth furnished with five rows of minute, but very sharp teeth.

PRIVET, in botany. See LIGUSTRUM.

PRIVILEGE, in law, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law.

Privileges are said to be personal or real. Personal privileges are such as are extended to peers, ambassadors, members of parliament and of the convocation, and their menial servants, &c. A real privilege is that granted to some particular place; as the king's palace, the courts at Westminster, the universities, &c.

PRIVY, in law, denotes one who is partaker, or has an interest, in an affair.

PRIVY COUNCIL, is the principal council belonging to the king, and is generally called by way of eminence the council.

Privy counsellors are made by the king's nomination without either patent or grant; and on taking the necessary oaths, they become immediately privy counsellors during the life of the king that chooses them, but subject to removal at his discretion. No inconvenience now arises from the extension of the number of the privy council, as those only attend who are especially summoned for that particular occasion.

PRIVY SEAL, is a seal that the king uses to such grants, or other things, as pass the great seal.

PRIZE, or PRISE, in maritime affairs, a vessel taken at sea from the enemies of a state, or from pirates; and that either by a ship of war, a privateer, &c. having a commission for that purpose.

Vessels are looked on as prize, if they fight under any other standard than that of the state from which they have their commission; if they have no charter-party, invoice, or bill of lading, aboard; if loaded with effects belonging to the king's enemies, or with contraband goods. Those of the king's subjects recovered from the enemy, after remaining twenty-four hours in their hands, are deemed lawful prize.

Vessels that refuse to strike, may be constrained; and if they make resistance and fight, become lawful prize if taken.

In ships of war, the prizes are to be divided among the officers, seamen, &c. as his majesty shall appoint by proclamation; but among privateers, the division is according to the agreement between the owners.

By stat. 13 Geo. II. c. 4. judges and officers, failing of their duty, in respect to the condemnation of prizes, forfeit five hundred pounds, with full costs of suit: one moiety to the king, and the other to the informer.

PROA, *flying*, in navigation, is a name given to a vessel used in the South Seas, because with a brisk trade-wind it sails near twenty miles an hour. In the construction of the proa, the head and stern are exactly alike, but the sides are very different; the side intended to be always the lee-side being flat; and the windward side made rounding, in the manner of other vessels; and to prevent her oversetting, which from her small breadth, and the straight run of her leeward side, would, without this precaution, infallibly happen, there is a frame laid out of her from windward, to the end of which is fastened a log, fashioned in the shape of a small boat and made hollow. The weight of the frame is intended to balance the proa, and the small boat is by its buoyancy (as it is always in the water) to prevent her oversetting to windward; and this frame is usually called an outrigger. The body of the vessel is made of two pieces joined endwise, and sewed together with bark, for there is no iron used about her; she is about two inches thick at the bottom, which at the gunwale is reduced to less than one. The sail is made of matting, and the mast, yard, boom, and outriggers, are all made of bamboo.

PROBABILITY of an event, in the doctrine of chances, is greater or less according to the number of chances by which it may happen or fail. (See EXPECTATION.) The probability of life is liable to rules of computation. In the Encyclopedie Methodique, we find a table of the probabilities of the duration of life, constructed from that which is to be found in the seventh volume of the Supplemens à l'Histoire de M. de Buffon, of which the following is an abridgement.

Of 23,994 children born at the same time, there will probably die,

$\frac{1}{3}$	In one year -	7998
$\frac{2}{3}$	Remaining $\frac{2}{3}$ or 15996	
$\frac{1}{2}$	In eight years -	11297
$\frac{1}{2}$	Remaining $\frac{1}{2}$ or 11997	
$\frac{2}{3}$	In thirty-eight years -	15996
$\frac{1}{3}$	Remaining $\frac{1}{3}$ or 7998	
$\frac{3}{4}$	In fifty years -	17994
$\frac{1}{4}$	Remaining $\frac{1}{4}$ or 5999	
$\frac{5}{6}$	In sixty-one years -	19995
$\frac{1}{6}$	Remaining $\frac{1}{6}$ or 3992	
$\frac{9}{10}$	In seventy years - -	21595
$\frac{1}{10}$	Remaining $\frac{1}{10}$ or 2399	
$\frac{39}{40}$	In eighty years - -	22395
$\frac{1}{40}$	Remaining $\frac{1}{40}$ or 599	
$\frac{299}{300}$	In ninety years - -	23914
$\frac{1}{300}$	Remaining $\frac{1}{300}$ or 80	
	In a hundred years - -	23992
	Remaining $\frac{1}{10000}$ or 2.	

PROBATE. See WILL.

PROBE, a surgeon's instrument for examining the circumstances of wounds, &c. See SURGERY.

PROBLEM, in logic, a proposition that neither appears absolutely true nor false; and consequently may be asserted either in the affirmative or negative.

PROBLEM, in geometry, is a proposition wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See GEOMETRY.

PROBLEM, in algebra, is a question or proposition which requires some unknown truth to be investigated, and the truth of the discovery demonstrated.

PROBLEM, *Kepler's*, in astronomy, is the determining a planet's residence from the time; so called from Kepler, who first proposed it. It was this: to find the position of a right line, which, passing through one of the foci of an ellipsis, shall cut off an area described by its motion, which shall be in any given proportion to the whole area of the ellipsis.

The proposer knew no way of solving the problem but by an indirect method; but sir Isaac Newton, Dr. Keil, &c. have since solved it directly and geometrically several ways.

PROBLEMATICAL RESOLUTION, in algebra, a method of solving difficult questions by certain rules, called canons.

PROBOSCIS, in natural history, is the trunk or snout of an elephant, and some other beasts and insects.

PROCEDENDO, in law, a writ whereby a plea or cause, formerly called from an inferior court to the court of chancery, king's bench, or court of common pleas, by writ of privilege, habeas corpus, or certiorari, is released, and returned to the other court to be proceeded in, upon its appearing that the defendant has no cause of privilege, or that the matter in the party's allegation is not well proved.

PROCELLARIA, in ornithology; a genus of birds, belonging to the order of anseres. The beak is somewhat compressed, and without teeth; the mandibles are equal, the superior one being crooked at the point; the feet are palmated, the hind claw being sessile, without any toe. Mr. Latham enumerates twenty-four species, which are principally distinguished by their colour. The most remarkable are:

1. The onicrea, petrel, or fulmar. The size of this bird is rather superior to that of the common gull: the bill very strong, much hooked at the end, and of a yellow colour. The nostrils are composed of two large tubes, lodged in one sheath: the head, neck, whole under side of the body, and tail, are white; the back and coverts of the wings ash-coloured; the quill-feathers dusky; and the legs yellowish. In lieu of a back toe, it has only a sort of spur, or sharp straight nail. These birds feed on the blubber or fat of whales, &c. which being soon convertible into oil, supplies them constantly with means of defence, as well as provision for their young, which they cast up into their mouths. They are likewise said to feed on sorrel, which they use to qualify the unctuous diet they live on. This species inhabits the isle of St. Kilda; makes its appearance there in November, and continues the whole year, except September and October; it lays a large, white, and very brittle egg, and the young are hatched the middle of June. No bird is of such use to the islanders as this: the fulmar supplies them with oil for their lamps, down for their beds, a delicacy for their tables, a balm for their wounds, and a medicine for their distempers. The fulmar is also a certain prognosticator of the change of the wind: if it comes to land, no west wind is expected for some time; and the contrary when it returns and keeps the sea. The whole genus of petrels have a peculiar faculty of spouting from their bills to a considerable distance, a large quantity of pure oil; which they do by way of defence, into the face of any one that attempts to take them; so that they are, for the sake of this panacea, seized by surprise; as this oil is subservient to the above-mentioned medical purposes. Martin tells us, it has been used in London and Edinburgh with success in rheumatic cases. Frederick Martens, who had the opportunity of seeing vast numbers of these birds in Spitzbergen, observes, that they are very bold, and resort after the whale-fishers in great flocks; and that, when a whale is taken, they will, in spite of all endeavours, light on it and pick out large lumps of fat, even when the animal is alive: that the whales are often discovered at sea, by the multitudes of them flying; and that, when one of the former is wounded, prodigious multitudes immediately follow its bloody track. He adds, that it is a most gluttonous bird, eating till it is forced to disgorge itself.

2. The puffinus, or shear-water, is fifteen inches in length; the breadth thirty-one; the weight seventeen ounces; the bill is an inch and three quarters long; nostrils tubular, but not very prominent; the head, and whole upper sides of the body, wings, tail, and thighs, are of a sooty blackness; the under side from chin to tail, and inner coverts of the wings, white; the legs weak, and compressed sideways; dusky behind, whitish before. These birds are found in the Calf of Man; and, as Mr. Ray supposes, in the Scilly isles. They resort to the former in February, take a short possession of the rabbit-burrows there, and then disappear till April. They lay one egg, white, and blunt at each end; and the young are fit to be taken the beginning of August, when great numbers are killed by the person who farms the island; they are salted and barrelled; and when they are boiled, are eaten with potatoes. During the day they keep at sea, fishing; and towards evening return to their young, whom they feed by discharging the contents of their stomachs into their mouths, which by that time is turned into oil: from the backward situation of their legs, they sit quite erect. They quit the island the latter end of August, or beginning of September; and we have reason to imagine that, like the

storm-finch, they are dispersed over the whole Atlantic ocean.

3. The pelagica, or stormy petrel, is about the bulk of the house-swallow; the length six inches; the extent of wings thirteen. The whole bird is black, except the coverts of the tail and vent-feathers, which are white; the bill is hooked at the end; the nostrils tubular; the legs slender and long. It has the same faculty of spouting oil from its bill as the other species; and Mr. Brunnich tells us, that the inhabitants of the Ferroe islands make this bird serve the purposes of a candle, by drawing a wick through the mouth and rump, which being lighted, the flame is fed by the fat and oil of the body. Except in breeding-time, it is always at sea, and is seen all over the vast Atlantic ocean, at the greatest distance from land; often following the vessels in great flocks, to pick up any thing that falls from on board: for trial sake, chopped straw has been flung over, which they would stand on with expanded wings, but were never observed to settle or swim in the water: it presages bad weather, and cautions the seamen of the approach of a tempest, by collecting under the stern of the ships; it braves the utmost fury of the storm, sometimes skimming with incredible velocity along the hollows of the waves, sometimes on the summits.

PROCESS, is the manner of proceeding in every cause, being the writs and precepts that proceed or go forth upon the original in every action, being either original or judicial. Britton, 138. Process is only meant to bring the defendant into court, in order to contest the suit, and abide the determination of the law. See Impey's Practice.

PROCKIA, a genus of the polyandria monogynia class and order. The cal. is three-leaved; cor. none; berry five-cornered, many-seeded. There is one species, a shrub of Santa Cruz.

PROCLAMATION, a public notice given of any thing of which the king thinks proper to advertise his subjects. Proclamations are a branch of the king's prerogative, and no person can make them without the king's authority, except mayors of towns, &c. by custom or privilege. Proclamations which require the people to do, or not to do, certain things, have the force of laws; but then they are supposed to be consistent with the laws already in being, otherwise they are superseded.

PROCREATION. See PHYSIOLOGY.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law. The proctors of the clergy, are the representatives chosen by the clergy to sit in the lower house of convocation; of these there are two for each diocese, and one for each collegiate church.

PROCURATOR, a person who has a charge committed to him to act for another. Thus the proxies of the lords in parliament are, in our law-books, called procurators; the bishops are sometimes called procuratores ecclesiarum; and the representatives sent by the clergy to convocation, procuratores cleri. The word is also used for a vicar or lieutenant; and we read of a procurator regni, who was an antient magistrate. Those who manage causes in Doctors' Commons, are also called procurators or proctors. In our statutes, he who gathers the fruits of a benefice for another is particularly called a procurator, and the instrument impowering him to receive them is termed a procuracy.

PROCYON, in astronomy, a fixed star of the second magnitude in the constellation called Canis minor. See CANIS.

PRODUCING, in geometry, signifies the drawing out a line farther till it has any assigned length.

PRODUCT, in arithmetic and geometry, the factum of two or more numbers, or lines, &c. into one another: thus $5 \times 4 = 20$ the product required.

In lines it is always (and in numbers sometimes) called the rectangle between the two lines, or numbers, multiplied by one another.

PROFILE, the draught of a building, fortification, &c. See ARCHITECTURE.

PROFILE also denotes the outline of a figure, building, member of architecture, &c.

PROFILE, in sculpture and painting, denotes a head, portrait, &c. when represented sideways, or in a side view. On almost all medals, faces are represented in profile.

PROGRESSION, an orderly advancing or proceeding in the same manner, course, tenor, proportion, &c.

Progression is either arithmetical, or geometrical.

Arithmetical PROGRESSION, is a series of quantities proceeding by continued equal differences, either increasing or decreasing. Thus,

increasing 1, 3, 5, 7, 9, &c. or
decreasing 21, 18, 15, 12, 9, &c;

where the former progression increases continually by the common difference 2, and the latter series or progression decreases continually by the common difference 3.

1. And hence, to construct an arithmetical progression, from any given first term, and with a given common difference; add the common difference to the first term, to give the 2d; to the 2d, to give the 3d; to the 3d, to give the 4th; and so on; when the series is ascending or increasing: but subtract the common difference continually, when the series is a descending one.

2. The chief property of an arithmetical progression, and which arises immediately from the nature of its construction, is this; that the sum of its extremes, or first and last terms, is equal to the sum of every pair of intermediate terms that are equidistant from the extremes, or to the double of the middle term when there is an uneven number of the terms.

Thus,

	1,	3,	5,	7,	9,	11,	13,
	13,	11,	9,	7,	5,	3,	1,
Sums	14	14	14	14	14	14	14,

where the sum of every pair of terms is the same number, 14.

Also,	a.	$a+d$,	$a+2d$,	$a+3d$,	$a+4d$,
	$a+4d$,	$a+3d$,	$a+2d$,	$a+d$,	a
sums	$2a+4d$	$2a+4d$	$2a+4d$	$2a+4d$	$2a+4d$.

3. And hence it follows, that double the sum of all the terms in the series, is equal to the sum of the two extremes multiplied by the number of the terms and consequently, that the single sum of all the terms of the series, is equal to half the said product. So the sum of the 7 terms

$$1,\ 3,\ 5,\ 7,\ 9,\ 11,\ 13,$$

$$\text{is } \overline{1+13} \times \tfrac{7}{2} = \tfrac{14}{2} \times 7 = 49.$$

And the sum of the five terms

$$a,\ a+d,\ a+2d,\ a+3d,\ a+4d.$$

$$\text{is } \overline{a+a+4d} \times \tfrac{5}{2}.$$

4. Hence also, if the first term of the progression is 0, the sum of the series will be equal to half the product of the last term multiplied by the number of terms: *i. e.* the sum of

$$0 + d + 2d + 3d + 4d \text{ - - - - - - } \overline{n-1}\,.\,d$$
$$= \tfrac{1}{2}n\,.\,\overline{n-1}\,.\,d,$$

where n is the number of terms, supposing 0 to be one of them. That is, in other words, the sum of an arithmetical progression, whether finite or infinite, whose first term is 0, is to the sum of as many times the greatest term, in the ratio of 1 to 2.

5. In like manner, the sum of the squares of the terms of such a series, beginning at 0, is to the sum of as many terms each equal to the greatest, in the ratio of 1 to 3. And,

6. The sum of the cubes of the terms of such a series, is to the sum of as many times the greatest term, in the ratio of 1 to 4.

7. And universally, if every term of such a progression is raised to the mth power, then the sum of all those powers will be to the sum of as many terms equal to the greatest, in the ratio of $m+1$ to 1. That is,

$$\text{the sum } 0 + d + 2d + 3d \text{ - - - - - - } l,$$
$$\text{is to } l^m + l^m + l^m + l^m \text{ - - - - - - } l^m,$$

in the ratio of 1 to $m+1$.

8. A synopsis of all the theorems, or relations, in an arithmetical progression, between the extremes or first and last term, the sum of the series, the number of terms, and the common difference, is as follows: viz. if

a denotes the least term,
z the greatest term,
d the common difference,
n the number of terms,
s the sum of the series;

then will each of these five quantities be expressed in terms of the others, as below:

$$a = z - \overline{n-1}\,.\,d = \frac{2s}{n} - z = \frac{s}{n} - \frac{n-1}{2}d = \sqrt{\overline{\tfrac{1}{2}d+z}|^2 - 2ds} + \tfrac{1}{2}d.$$

$$z = a + \overline{n-1}\,.\,d = \frac{2s}{n} - a = \frac{s}{n} + \frac{n-1}{2}d = \sqrt{\overline{\tfrac{1}{2}d-a}|^2 + 2ds} - \tfrac{1}{2}d.$$

$$d = \frac{z-a}{n-1} = \frac{s-na}{n-1}\,.\,\frac{2}{n} = \frac{nz-s}{n-1}\,.\,\frac{2}{n} = \frac{z+a\,.\,z-a}{2s-a-z}.$$

$$n = \frac{z-a}{d} + 1 = \frac{2s}{a+z} = \frac{\tfrac{1}{2}d - a + \sqrt{\overline{\tfrac{1}{2}d-a}|^2 + 2ds}}{d} = \frac{\tfrac{1}{2}d + z - \sqrt{\overline{\tfrac{1}{2}d+z}|^2 - 2ds}}{d}$$

$$\frac{a+z}{2}n = \frac{a+z}{2}\,.\,\frac{z-a+d}{d} = \frac{2a+\overline{n-1}\,.\,d}{2}n = \frac{2z-\overline{n-1}\,.\,d}{2}n.$$

And most of these expressions will become much simpler if the first term is 0 instead of a.

Geometrical PROGRESSION, is a series of quantities proceeding in the same continual ratio or proportion, either increasing or decreasing; or it is a series of quantities that are continually proportional; or which increase by one common multiplier, or decrease by one common divisor; which common multiplier or divisor is called the common ratio. As,

increasing, 1, 2, 4, 8, 16, &c.
decreasing, 81, 27, 9, 3, 1, &c.;

where the former progression increases continually by the common multiplier 2, and the latter decreases by the common divisor 3.

Or ascending, $a,\ ra,\ r^2a,\ r^3a$, &c.

or descending, $a,\ \frac{a}{r},\ \frac{a}{r^2},\ \frac{a}{r^3}$, &c;

where the first term is a, and common ratio r.

1. Hence, the same principal properties obtain in a geometrical progression, as have been remarked of the arithmetical one, using only multiplication in the geometricals for addition in the arithmeticals, and division in the former for subtraction in the latter. So that, to construct a geometrical progression, from any given first term, and with a given common ratio; multiply the 1st term continually by the common ratio for the rest of the terms, when the series is an ascending one; or divide continually by the common ratio, when it is a descending progression.

2. In every geometrical progression, the product of the extreme terms is equal to the product of every pair of the intermediate terms that are equidistant from the extremes, and also equal to the square of the middle term when there is a middle one, or an uneven number of the terms.

Thus,	1,	2,	4,	8,	16,
	16	8	4	2	1
prod.	16	16	16	16	16.

3. The last term of a geometrical progression, is equal to the first term multiplied, or divided, by the ratio raised to the power whose exponent is less by 1 than the number of terms in the series; so $z = ar^{n-1}$, when the series is an ascending one, or $z = \frac{a}{r^{n-1}}$, when it is a descending progression.

4. As the sum of all the antecedents, or all the terms except the least, is to the sum of all the consequents, or all the terms except the greatest, so is 1 to r, the ratio. For,

if $a + ra + r^2a + r^3a$ are all except the last, then $ra + r^2a + r^3a + r^4a$ are all except the first; where it is evident that the former is to the latter as 1 to r, or the former multiplied by r gives the latter. So that, z denoting the last term, a the first term, and r the ratio, also s the sum of all the terms; then $s - z : s - a :: 1 : r$, or $\overline{s - a} = \overline{s - z} \cdot r$. And from this equation all the relations among the four quantities a, z, r, s, are easily derived; such as, $s = \frac{rz - a}{r - 1}$; viz. multiply the greatest term by the ratio, subtract the least term from the product, then the remainder divided by 1 less than the ratio, will give the sum of the series. And if the least term a is 0, which happens when the descending progression is infinitely continued, then the sum is barely $\frac{rz}{r-1}$. As in the infinite progression $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8}$ &c. where $z = 1$, and $r = 2$, it is s or $\frac{rz}{r-1} = \frac{2}{2-1} = \frac{2}{1} = 2$.

5. The first or least term of a geometrical progression, is to the sum of all the terms, as the ratio minus 1, to the nth power of the ratio minus 1; that is, $a : s :: r - 1 : r^n - 1$.

Other relations among the five quantities a, z, r, n, s, where

a denotes the least term,
z the greatest term,
r the common ratio,
n the number of terms,
s the sum of the progression,

are as below; viz.

$$a = \frac{z}{r^{n-1}} = zr - (r-1)s = \frac{r-1}{r^n - 1}s.$$

$$z = ar^{n-1} = \frac{a + (r-1)s}{r} = \frac{r-1}{r^n - 1}sr^{n-1}.$$

$$r = \frac{s-a}{s-z} = \sqrt[n-1]{\frac{z}{a}}.$$

$$n = \frac{\log \frac{rz}{a}}{\log. r} = \frac{\log. \frac{a + (r-1)s}{a}}{\log. r} = \frac{\log. \frac{rz}{rz - (r-1)s}}{\log. r} = \frac{\log. \frac{s-a \cdot z}{s-z \cdot a}}{\log. \frac{s-a}{s-z}}.$$

$$s = \frac{rz - a}{r-1} = \frac{r^n - 1}{r-1}a = \frac{r^n - 1}{r-1} \cdot \frac{z}{r^{n-1}} = \frac{\sqrt[n-1]{z^n} - \sqrt[n-1]{a^n}}{\sqrt[n-1]{z} - \sqrt[n-1]{a}}.$$

And the other values of a, z, and r, are to be found from these equations, viz.

$$(s-z)^{n-1}z = (s-a)^{n-1}a,$$

$$r^n - \frac{s}{a}r = 1 - \frac{s}{a},$$

$$r^n - \frac{s}{s-z}r^{n-1} = \frac{z}{s-z}.$$ See SERIES.

PROHIBITION, is a writ properly issuing only out of the court of king's bench, being the king's prerogative writ; but, for the furtherance of justice, it may now also be had in some cases out of the court of chancery, common pleas, or exchequer, directed to the judge and parties of a suit in an inferior court, commanding them to cease from the prosecution thereof, upon a suggestion, that either the cases originally, or some collateral matter arising therein, does not belong to that jurisdiction, but the cognizance of some other court. 3 Black. 112.

Upon the court being satisfied that the matter alleged by the suggestion is sufficient, the writ of prohibition immediately issues; commanding the judge not to hold, and the party not to prosecute, the plea. And if either the judge or party shall proceed after such prohibition, an attachment may be had against them for the contempt, by the court that awarded it, and an action will lie against them to repair the party in damages. 3 Black. 113.

PROJECTILE, or PROJECT, in mechanics, is any body which, being put into a violent motion by an external force impressed upon it, is dismissed from the agent, and left to pursue its course; such as a stone thrown out of the hand or a sling, an arrow from a bow, a ball from a gun, &c.

PROJECTILES, the science of the motion, velocity, flight, range, &c. of a projectile put into violent motion by some external cause, as the force of gunpowder, &c. This is the foundation of gunnery, under which article may be found all that relates peculiarly to that branch.

All bodies, being indifferent as to motion or rest, will necessarily continue the state they are put into, except so far as they are hindered, and forced to change it by some new cause. Hence, a projectile, put in motion, must continue eternally to move on in the same right line, and with the same uniform or constant velocity, were it to meet with no resistance from the medium, nor had any force of gravity to encounter.

In the first case, the theory of projectiles would be very simple indeed; for there would be nothing more to do, than to compute the space passed over in a given time by a given constant velocity: or either of these, from the other two being given.

But by the constant action of gravity, the projectile is continually deflected more and more from its right-lined course, and that with an accelerated velocity: which, being combined with its projectile impulse, causes the body to move in a curvilineal path, with a variable motion, which path is the curve of a parabola, as will be proved below; and the determination of the range, time of flight, angle of projection, and variable velocity, constitutes what is usually meant by the doctrine of projectiles, in the common acceptation of the word.

What is said above, however, is to be understood of projectiles moving in a non-resisting medium; for when the resistance of the air is also considered, which is enormously great, and which very much impedes the first projectile velocity, the path deviates greatly from the parabola, and the determination of the circumstances of its motion becomes one of the most complex and difficult problems in nature.

In the first place, therefore, it will be proper to consider the common doctrine of projectiles, or that on the parabolic theory, or as depending only on the nature of gravity and the projectile motion, as abstracted from the resistance of the medium.

Little more than 200 years ago, philosophers took the line described by a body projected horizontally, such as a bullet out of a cannon, while the force of the powder greatly exceeded the weight of the bullet, to be a right line, after which they allowed it became a curve. Nicholas Tartaglia was the first who perceived the mistake; maintaining that the path of the bullet was a curved line through the whole of its extent. But it was Galileo who first determined what particular curve it is that a projectile describes; shewing that the path of a bullet projected horizontally from an eminence, was a parabola, the vertex of which is the point where the bullet quits the cannon. And the same is proved generally, in the 2d article following, when the projection is made in any direction whatever, viz. that the curve is always a parabola, supposing the body moves in a non-resisting medium.

The Laws of the Motion of PROJECTILES.

I. If a heavy body is projected perpendicularly, it will continue to ascend or descend perpendicularly; because both the projecting and the gravitating force are found in the same line of direction.

II. If a body is projected in free space, either parallel to the horizon, or in any oblique direction; it will, by this motion in conjunction with the action of gravity, describe the curve line of a parabola. (Fig. 1.)

For, let the body be projected from A, in the direction AD, with any uniform velocity; then in any equal portions of time it would, by that impulse alone, describe the equal spaces AB, BC, CD, &c. in the line AD, if it was not drawn continually down below that line by the action of gravity. Draw BE, CF, DG, &c. in the direction of gravity, or perpendicular to the horizon; and take BE, CF, DG, &c. equal to the spaces through which the body would descend by its gravity in the same times in which it would uniformly pass over the spaces AB, AC, AD, &c. by the projectile motion. Then, since by these motions, the body is carried over the space AB in the same time as the space BE, and the space AC in the same time as the space CF, and the space AD in the same time as the space DG, &c.; therefore, by the composition of motions, at the end of those times the body will be found respectively in the points E, F, G, &c. and consequently the real path of the projectile will be the curve line AEFG, &c. But the spaces AB, AC, AD, &c. being described by uniform motion, are as the times of description; and the spaces BE, CF, DG, &c. described in the same times by the accelerating force of gravity, are as the squares of the times; consequently the perpendicular descents are as the squares of the spaces in AD,

that is, - - - - BE, CF, DG, &c,
are respectively propor-
tional to - - - AB^2, AC^2, AD^2, &c.

which is the same as the property of the parabola. Therefore the path of the projectile is the parabolic line AEFG, &c. to which AD is a tangent at the point A.

Hence, 1. The horizontal velocity of a projectile is always the same constant quantity, in every point of the curve; because the horizontal motion is in a constant ratio to the motion in AD, which is the uniform projectile motion; viz. the constant horizontal velocity being to the projectile velocity, as radius to the cosine of the angle DAH, or angle of elevation or depression of the piece above or below the horizontal line AH.

2. The velocity of the projectile in the direction of the curve, or of its tangent, at any point A, is as the secant of its angle BAI of direction above the horizon. For the motion in the horizontal direction AI being constant, and AI being to AB as radius to the secant of the angle A; therefore the motion at A, in AB, is as the secant of the angle A.

3. The velocity in the direction DG of gravity, or perpendicular to the horizon, at any point G of the curve, is to the first uniform projectile velocity at A, as 2GD to AD. For the times of describing AD and DG being equal, and the velocity acquired by freely descending through DG being such as would carry the body uniformly over twice DG in an equal time, and the spaces described with uniform motions being as the velocities, it follows that the space AD is to the space 2DG, as the projectile velocity at A is to the perpendicular velocity at G.

III. The velocity in the direction of the curve, at any point of it, as A, is equal to that which is generated by gravity in freely descending through a space which is equal to one-fourth of the parameter of the diameter to the parabola at that point. (Fig. 2.)

Let PA or AB be the height due to the velocity of the projectile at any point A, in the direction of the curve or tangent AC, or the velocity acquired by falling through that height; and complete the parallelogram ACDB. Then is CD = AB or AP, the height due to the velocity in the curve at A; and CD is also the height due to the perpendicular velocity at D, which will therefore be equal to the former: but, by the last corollary, the velocity at A is to the perpendicular velocity at D, as AC to 2CD; and as these velocities are equal, therefore AC or BD is equal to 2CD or 2AB; and hence AB or AP is equal to $\frac{1}{2}$BD, or $\frac{1}{4}$ of the parameter of the diameter AB, by the nature of the parabola.

Hence, 1. If through the point P, the line PL is drawn perpendicular to AP; then the velocity in the curve at every point, will be equal to the velocity acquired by falling through the perpendicular distance of the point from the said line PL; that is, a body falling freely through

PA, acquires the velocity in the curve at A,
EF, - - - - - at F,
KD, - - - - - at D,
LH, - - - - - at H.

The reason of which is, that the line PL is what is called the directrix of the parabola; the property of which is, that the perpendicular to it, from every point of the curve, is equal to one-fourth of the parameter of the diameter at that point, viz.

PA = $\frac{1}{4}$ the parameter of the diameter at A,
EF = - - - - - at F,
KD = - - - - - at L,
LH = - - - - - at H.

2. If a body, after falling through the height PA, which is equal to AB, and when it arrives at A, if its course is changed, by reflection from a firm plane AI, or otherwise, into any direction AC, without altering the velocity; and if AC is taken equal to 2AP or 2AB, and the parallelogram is completed; the body will describe the parabola passing through the point D.

3. Because AC = 2AB, or 2CD, or 2AP; therefore AC^2 = 2AP . 2CD, or AP . 4CD; and because all the perpendiculars EF, CD, GH, are as AE^2, AC^2, AG^2 therefore, also AP . 4EF = AE^2, and AP . 4GH = AG^2, &c.; and because the rectangle of the extremes is equal to the rectangle of the means, of four proportionals, therefore it is always,

AP : AE :: AE : 4EF,
and AP : AC :: AC : 4CD,
and AP : AG :: AG : 4GH,
and so on.

IV. Having given the direction of a projectile, and the impetus or altitude due to the first velocity; to determine the greatest height to which it will rise, and the random or horizontal range. (Fig. 3.)

Let AP be the height due to the projectile velocity at A, or the height which a body must fall to acquire the same velocity as the projectile has in the curve at A; also AG the direction, and AH the horizon. Upon AG let fall the perpendicular PQ, and on AP the perpendicular QR; so shall AR be equal to the greatest altitude CV, and 4RQ equal to the horizontal range AH. Or, having drawn PQ perpendicular to AG, take AG = 4AQ, and draw GH perpendicular to AH; then AH is the range.

For, by the last cor. AP : AG :: AG : 4GH,
and by sim. triangles, AP : AG :: AQ : GH,
or AP : AG :: 4AQ : 4GH;

therefore AG = 4AQ; and, by similar triangles, AH = 4RQ.

Also, if V is the vertex of the parabola, then AB or $\frac{1}{2}$AG = 2AQ, or AQ = QB; consequently AR = BV, which is = CV by the nature of the parabola.

Hence, 1. Because the angle Q is a right angle, which is the angle in a semicircle: therefore if upon AP as a diameter a semicircle is described, it will pass through the point Q. (Fig. 4.)

2. If the horizontal range and the projectile velocity are given, the direction of the piece so as to hit the object H will be thus easily found: Take AD = $\frac{1}{4}$AH, and draw DQ perpendicular to AH, meeting the semicircle described on the diameter AP in Q and q: then either AQ or Aq will be the direction of the piece. And hence it appears, that there are two directions AB and Ab which, with the same projectile velocity, give the very same horizontal range AH: and these two directions make equal angles qAD and QAP with AH and AP, because the arc PQ is equal to the arc Aq.

3. Or if the range AH and direction AB are given, to find the altitude and velocity or impetus: Take AD = $\frac{1}{4}$AH, and erect the perpendicular DQ meeting AB in Q; so shall DQ be equal to the greatest altitude CV. Also erect AP perpendicular to AH, and QP to AQ so shall AP be the height due to the velocity.

4. When the body is projected with the same velocity, but in different directions; the horizontal ranges AH will be as the sines of double the angles of elevation; or, which is the same thing, as the rectangle of the sine and cosine of elevation. For AD or RQ, which is $\frac{1}{4}$AH, is the sine of the arc AQ, which measures double the angle QAD of elevation.

And when the direction is the same, but the velocities different, the horizontal ranges are as the square of the velocities, or as the height AP, which is as the square of the velocity; for the sine AD or RQ, or $\frac{1}{4}$AH, is as the radius, or as the diameter AP.

Therefore, when both are different, the ranges are in the compound ratio of the squares of the velocities, and the sines of double the angles of elevation.

5. The greatest range is when the angle of elevation is half a right angle, or 45°. For the double of 45 is 90°, which has the greatest sine. Or the radius OS, which is $\frac{1}{4}$ of the range, is the greatest sine.

And hence the greatest range, or that at an elevation of 45°, is just double the altitude AP, which is due to the velocity, or equal to 4VC. And consequently, in that case, C is the focus of the parabola, and AH its parameter.

And the ranges are equal at angles equally above and below 45°.

6. When the elevation is 15°, the double of which, or 30°, having its sine equal to half the radius, consequently its range will be equal to AP, or half the greatest range at the elevation of 45°; that is, the range at 15° is equal to the impetus or height due to the projectile velocity.

7. The greatest altitude CV, being equal to AR, is as the versed sine of double the angle of elevation, and also as AP or the square of the velocity. Or as the square of the sine of elevation, and the square of the velocity; for the square of the sine is as the versed sine of the double angle.

8. The time of flight of the projectile, which is equal to the time of a body falling freely through GH or 4CV, 4 times the altitude, is therefore as the square root of the altitude, or as the projectile velocity and sine of the elevation.

9. And hence may be deduced the following set of theorems, for finding all the circumstances relating to projectiles on horizontal planes, having any two of them given. Thus, let

s, c, t = sine, cosine, and tang. of elevation,
S, v = sine and vers. of double the elevation,

R the horizontal rage, T the time of flight, V the projectile velocity, H the greatest height of the projectile, $g = 16\frac{1}{12}$ feet, and a = the impetus or the altitude due to the velocity V. Then,

$$R = 2aS = 4asc = \frac{SV^2}{2g} = \frac{scV^2}{g} = \frac{gcT^2}{s} = \frac{gT^2}{t}$$
$$= \frac{4H}{t}.$$

$$V = \sqrt{4ag} = \sqrt{\frac{2gR}{S}} = \sqrt{\frac{gR}{sc}} = \frac{gT}{s} = \frac{2\sqrt{gH}}{s}$$

$$T = \frac{sV}{g} = 2s\sqrt{\frac{a}{g}} = \sqrt{\frac{tR}{g}} = \sqrt{\frac{sR}{gc}} = 2\sqrt{\frac{H}{g}}$$

$$H = as^2 = \tfrac{1}{2}av = \tfrac{1}{4}tR = \frac{sR}{4c} = \frac{sV^2}{4g} = vV^4$$
$$= \frac{gT^2}{4}.$$

And from any of these, the angle of direction may be found.

V. To determine the range on an oblique plane; having given the impetus or the velocity, and the angle of direction.

Let AE be the oblique plane, at a given angle above or below the horizontal plane AH; AG the direction of the piece; and AP the altitude due to the projectile velocity at A. (Fig. 5.)

By the last prop. find the horizontal range AH to the given velocity and direction draw HE perpendicular to AH, meeting the oblique plane in E; draw EF parallel to the direction AG, and FI parallel to HE; so shall the projectile pass through I, and the range on the oblique plane will be AI. This is evident from the properties of the parabola: see CONIC SECTIONS, where it is proved, that if AH, AI, are any two lines terminated at the curve, and IF, HE, are parallel to the axis; then is EF parallel to the tangent AG. (Figs. 6 and 7.)

Hence, 1. If AO is drawn perpendicular to the plane AI, and AP is bisected by the perpendicular STO; then with the centre O describing a circle through A and P, the same will also pass through q; because the angle GAI, formed by the tangent AG and AI, is equal to the angle APq, which will therefore stand upon the same arc Aq.

2. If there are given the range and velocity, or the impetus, the direction will then be easily found thus: Take $Ak = \frac{1}{4}$AI; draw kq perpendicular to AH, meeting the circle described with the radius AO in two points q and q; then Aq or Aq will be the direction of the piece. And hence it appears that there are two directions, which, with the same impetus, give the very same range AI, on the oblique plane. And these two directions make equal angles with AI and AP, the plane and the perpendicular, because the arc Pq = the arc Aq. They also make equal angles with a line drawn from A through S, because the arc Sq = the arc Sq.

3. Or, if there are given the range AI, and the direction Aq, to find the velocity or impetus. Take $Ak = \frac{1}{4}$AI; and erect kq perpendicular to AH, meeting the line of direction in q; then draw qP, making the angle AqP = the angle Akq; so shall AP be the impetus, or altitude due to the projectile velocity.

4. The range on an oblique plane, with a given elevation, is directly as the rectangle of the cosine of the direction of the piece above the horizon, and the sine of the direction above the oblique plane, and reciprocally as the square of the cosine of the angle of the plane above or below the horizon.

For, put s = sin. ∠ qAI or APq,
c = cos. ∠ qAH or sin. PAq,
C = cos. ∠ IAH or sin. Akd or Akq or AqP.

Then, in the tri. APq, C : s :: AP : Aq,
and in the trian. Akq, C : c :: Aq : Ak,
therefore by compos. $C^2 : cs$ :: AP : $Ak = \frac{1}{4}$AI,
so that the oblique range $AI = \frac{cs}{C^2} \times 4AP$.

Hence the range is the greatest when Ak is the greatest, that is, when kq touches the circle in the middle point S; and then the line of direction passes through S, and bisects the angle formed by the oblique plane and the vertex. Also the ranges are equal at equal angles above and below this direction for the maximum.

5. The greatest height cv or kq of the projectile, above the plane, is equal to $\frac{s^2}{c^2} \times$ AP. And therefore it is as the impetus and square of the sine of direction above the plane directly, and square of the cosine of the plane's inclination reciprocally.

For, C (sin. AqP) : s (sin. APq) :: AP : Aq,
and C (sin. Akq) : s (sin. kAq) :: Aq : kq,
therefore by comp. $C^2 : s^2$ :: AP : kq.

6. The time of flight in the curve AvI is $= \frac{2s}{c}\sqrt{\frac{AP}{g}}$, where $g = 16\frac{1}{12}$ feet. And therefore it is as the velocity and sine of direction above the plane directly, and cosine of the plane's inclination reciprocally. For the time of describing the curve, is equal to the time of falling freely through GI, or $4kq$, or $\frac{4s^2}{c^2} \times$ AP. Therefore, the time being as the square root of the distance, $\sqrt{g} : \frac{2s}{c}\sqrt{AP} :: 1'' : \frac{2s}{c}\sqrt{\frac{AP}{g}}$ the time of flight.

7. From the foregoing corollaries may be collected the following set of theorems, relating to projectiles made on any given inclined planes, either above or below the horizontal plane; in which the letters denote as before, namely,

c = cos. of direction above the horizon,
C = cos. of inclination of the plane,
s = sin. of direction above the plane,
R the range on the oblique plane,
T the time of flight,
V the projectile velocity,
H the greatest height above the plane,
a the impetus, or alt. due to the velocity V,
$g = 16\frac{1}{12}$ feet. Then

$$R = \frac{cs}{C^2} \times 4a = \frac{cs}{C^2 g}V^2 = \frac{gC}{s}T^2 = \frac{4c}{s}H.$$

$$H = \frac{s^2}{C^2}a = \frac{s^2V^2}{4gC^2} = \frac{sR}{4c} = \frac{g}{4}T^2.$$

$$V = \sqrt{4ag} = C\sqrt{\frac{gR}{cs}} = \frac{gC}{s}T = \frac{2C}{s}\sqrt{gH}.$$

$$T = \frac{2s}{C}\sqrt{\frac{a}{g}} = \frac{sV}{gC} = \sqrt{\frac{sR}{gc}} = 2\sqrt{\frac{H}{g}}.$$

And from any of these, the angle of direction may be found.

Of the Path of PROJECTILES, *as depending on the Resistance of the Air.*

For a long time after Galileo, philosophers seemed to be satisfied with the parabolic theory of projectiles, deeming the effect of the air's resistance on the path as of no consequence. In process of time, however, as the true philosophy began to dawn, they began to suspect that the resistance of the medium might have some effect upon the projectile curve, and they set themselves to consider this subject with some attention.

Huygens, supposing that the resistance of the air was proportional to the velocity of the moving body, concluded that the line described by it would be a kind of logarithmic curve.

But Newton, having clearly proved, that the resistance to the body is not proportional to the velocity itself, but to the square of it, shews, in his Principia, that the line a projectile describes, approaches nearer to an hyperbola than a parabola.

Mr. Robins has shewn that, in some cases, the resistance to a cannon-ball amounts to more than 20 times the weight of the ball; and Dr. Hutton, having prosecuted this subject far beyond any former example, has sometimes found this resistance amount to near 100 times the weight of the ball, viz. when it moved with a velocity of 2000 feet per second, which is a rate of almost 23 miles in a minute.

Mr. Robins has not only detected the errors of the parabolic theory of gunnery, which takes no account of the resistance of the air, but shews how to compute the real range of resisted bodies.

There is an odd circumstance which often takes place in the motion of bodies projected with considerable force, which shews the great complication and difficulty of this subject; namely, that bullets in their flight are not only depressed beneath their original direction by the action of gravity, but are also frequently driven to the right or left of that direction by the action of some other force.

Now if it was true that bullets varied their direction by the action of gravity only, then it ought to happen that the errors in their flight to the right or left of the mark they were aimed at, should increase in the proportion of the distance of the mark from the piece only. But this is contrary to all experience: the same piece which will carry its bullet within an inch of the intended mark at 10 yards distance, cannot be relied on to 10 inches in 100 yards, much less to 30 in 300 yards.

And this inequality can only arise from the track of the bullet being incurvated sideways as well as downwards; for by this means the distance between the incurvated line and the line of direction, will increase in a much greater ratio than that of the distance; these lines coinciding at the mouth of the piece, and afterwards separating in the manner of a curve from its tangent, if the mouth of the piece is considered as the point of contact.

This is put beyond a doubt from the experiments made by Mr. Robins; who found also that the direction of the shot in the perpendicular line was not less uncertain, falling sometimes 200 yards short of what it did at other times, although there was no visible cause of difference in making the experiment. See RIFLE.

PROJECTION, in mechanics, the act of giving a projectile its motion.

If the direction of the force, by which the projectile is put in motion, is perpendicular to the horizon, the projection is said to be perpendicular; if parallel to the apparent horizon, it is said to be an horizontal projection; and if it makes an oblique angle with the horizon, the projection is oblique. In all cases, the angle which the line of direction makes with the horizontal line, is called the angle of elevation of the projectile, or of depression when the line of direction points below the horizontal line.

PROJECTION, in perspective, denotes the appearance or representation of an object on the perspective plane. So, the projection of a point, is a point where the optic ray passes from the objective point through the plane to the eye; or it is the point where the plane cuts the optic ray. And hence it is easy to conceive what is meant by the projection of a line, a plane, or a solid.

PROJECTION *of the Sphere in Plano*, is a representation of the several points or places of the surface of the sphere, and of the circles described upon it, upon a transparent plane placed between the eye and the sphere, or such as they appear to the eye placed at a given distance. For the laws of this projection, see PERSPECTIVE: the projection of the sphere being only a particular case of perspective.

The chief use of the projection of the sphere, is in the construction of planispheres, maps, and charts; which are said to be of this or that projection, according to the several situations of the eye, and the perspective plane, with regard to the meridians, parallels, and other points or places to be represented.

The most usual projection of maps of the world, is that on the plane of the meridian, which exhibits a right sphere; the first meridian being the horizon. The next is that on the plane of the equator, which has the pole in the centre, and the meridians the radii of a circle, &c. and this represents a parallel sphere. See MAP.

The projection of the sphere is usually divided into orthographic and stereographic; to which may be added gnomonic.

PROJECTION *orthographic*, is that in which the surface of the sphere is drawn upon a plane, cutting it in the middle; the eye being placed at an infinite distance vertically to one of the hemispheres. And, PROJECTION *stereographic* of the sphere, is that in which the surface and circles of the sphere are drawn upon the plane of a great circle, the eye being in the pole of that circle.

PROJECTION *gnomonical of the sphere*, is that in which the surface of the sphere is drawn upon a plane withoutside of it, commonly touching it, the eye being at the centre of the sphere.

Laws of the orthographic projection.—1. The rays coming from the eye, being at an infinite distance, and making the projection, are parallel to each other, and perpendicular to the plane of projection.

2. A right line perpendicular to the plane of projection, is projected into a point where that line meets the said plane. (Fig. 8.)

3. A right line, as AB, or CD, not perpendicular, but either parallel or oblique to the plane of the projection, is projected into a right line, as EF or GH, and is always comprehended between the extreme perpendiculars AE and BF, or CG and DH.

4. The projection of the right line AB is the greatest, when AB is parallel to the plane of the projection.

5. Hence it is evident, that a line parallel to the plane of the projection, is projected into a right line equal to itself; but a line that is oblique to the plane of projection, is projected into one that is less than itself. (Fig. 9.)

6. A plane surface, as ACBD, perpendicular to the plane of the projection, is projected into the right line, as AB, in which it cuts that plane. Hence it is evident, that the circle ACBD perpendicular to the plane of projection, passing through its centre, is projected into that diameter AB in which it cuts the plane of the projection. Also any arch as C*c* is projected into O*o*, equal to *ca*, the right sine of that arch; and the complemental arc *c*B is projected into *o*B, the versed sine of the same arc *c*B.

7. A circle parallel to the plane of the projection, is projected into a circle equal to itself, having its centre the same with the centre of the projection, and its radius equal to the cosine of its distance from the plane. And a circle oblique to the plane of the projection, is projected into an ellipsis, whose greater axis is equal to the diameter of the circle, and its less axis equal to double the cosine of the obliquity of the circle to a radius equal to half the greater axis.

Properties of the stereographic projection.—1. In this projection a right circle, or one perpendicular to the plane of projection, and passing through the eye, is projected into a line of half-tangents.

2. The projections of all other circles, not passing through the projecting point, whether parallel or oblique, are projected into circles. Figs. 10, 11, and 12.

Thus, let ACEDB represent a sphere, cut by a plane RS, passing through the centre I, perpendicular to the diameter EH, drawn from E the place of the eye; and let the section of the sphere by the plane RS be the circle CFDL, whose poles are H and E. Suppose now AGB is a circle on the sphere to be projected, whose pole most remote from the eye is P; and the visual rays from the circle HGB meeting in E, form the cone AGBE, of which the triangle AEB is a section through the vertex E, and diameter of the base AB; then will the figure *agbf*, which is the projection of the circle AGB, be itself a circle. Hence, the middle of the projected diameter is the centre of the projected circle, whether it is a great circle or a small one: also the poles and centres of all circles parallel to the plane of projection, fall in the centre of the projection: and all oblique great circles cut the primitive circle in two points diametrically opposite.

3. The projected diameter of any circle subtends an angle at the eye equal to the distance of that circle from its nearest pole, taken on the sphere; and that angle is bisected by a right line joining the eye and that pole. Thus, let the plane RS (fig. 13) cut the sphere HFEC through its centre I; and let ABC be any oblique great circle, whose diameter AC is projected into *ac*; and KOL any small circle parallel to ABC, whose diameter KL is projected in *kl*. The distances of those circles from their pole P, being the arcs AHP, KHP, and the angles *a*E*c*, *k*E*l*, are the angles at the eye, subtended by their projected diameters, *ac* and *kl*. Then is the angle *a*E*c* measured by the arc AHP, and the angle *k*E*l* measured by the arc KHP; and those angles are bisected by EP.

3. Any point of a sphere is projected at such a distance from the centre of projection, as is equal to the tangent of half the arc intercepted between that point and the pole opposite to the eye, the semidiameter of the sphere being radius. Thus, let C*b*EB (fig. 14) be a great circle of the sphere, whose centre is *c*; GH the plane of projection cutting the diameter of the sphere in *b* and B; also E and C the poles of the section by that plane; and *a* the projection of A. Then *ca* is equal to the tangent of half the arc AC, as is evident by drawing CF = the tangent of half that arc, and joining *c*F.

4. The angle made by two projected circles, is equal to the angle which these circles make on the sphere. For let IACE (fig. 15) and ABL be two circles on a sphere intersecting in A; E the projecting point; and RS the plane of projection, in which the point A is projected in *a*, in the line IC, the diameter of the circle ACE. Also let DH and FA be tangents to the circles ACE and ABL. Then will the projected angle *daf* be equal to the spherical angle BAC.

5. The distance between the poles of the primitive circle and an oblique circle, is equal to the tangent of half the inclination of those circles; and the distance of their centres is equal to the tangent of their inclination, the semidiameter of the primitive being radius. For let AC (fig. 16) be the diameter of a circle, whose poles are P and Q, and inclined to the plane of projection in the angle AIF; and let *a*, *c*, *p*, be the projections of the points A, C, P; also let H*a*E be the projected oblique circle, whose centre is *q*. Now when the plane of projection becomes the primitive circle, whose pole is I, then is I*p* = tangent of half the angle AIF, or of half the arch AF; and I*q* = tangent of AF, or of the angle FH*a* = AIF.

6. If through any given point in the primitive circle, an oblique circle is described, then the centres of all other oblique circles passing through that point, will be in a right line drawn through the centre of the first oblique circle, and perpendicular to a line passing through that centre, the given point, and the centre of the primitive circle. Thus, let GACE (fig. 17) be the primitive circle, and ADEI a great circle described through D, its centre being B. HK is a right line drawn through B, perpendicular to a right line CI passing through D and B and the centre of the primitive circle. Then the centres of all other great circles, as FDG, passing through D, will fall in the line HK.

7. Equal arcs of any two great circles of the sphere will be intercepted between two other circles drawn on the sphere through the remotest poles of those great circles. For let PBEA (fig. 18) be a sphere, on which AGB and CFD are two great circles, whose remotest poles are E and P; and through these poles let the great circle PBEC and the small circle PGE be drawn, cutting the great circles AGB and CFD in the points B, G, D, F. Then are the intercepted arcs BG and DF equal to one another.

8. If lines are drawn from the projected pole of any great circle, cutting the peripheries of the projected circle and plane of projection, the intercepted arcs of those peripheries are equal; that is, the arc BG = *df*.

9. The radius of any lesser circle, whose plane is perpendicular to that of the primitive circle, is equal to the tangent of that lesser circle's distance from its pole; and the secant of that distance is equal to the distance of the centres of the primitive and lesser circle. For let P (fig. 19) be the pole and AB the diameter of a lesser circle, its plane being perpendicular to that of the primitive circle, whose centre is C: then *d* being the centre of the projected lesser circle, *da* is equal to the tangent of the arc PA, and *d*C = the secant of PA.

PROJECTURE. See ARCHITECTURE.

PROLAPSUS. See SURGERY.

PROLATE, in geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its larger diameter.

PROMISE, is where, upon a valuable consideration, persons bind themselves by words to do or perform such a thing agreed on: it is in the nature of a verbal covenant, and wants only the solemnity of writing and sealing to make it absolutely the same. Yet for the breach of it, the remedy is different; for instead of an action of covenant, there lies only an action upon the case, the damages whereof are to be estimated and determined by the jury.

PROMISSORY NOTE. See BILLS OF EXCHANGE.

PRONOUN, in grammar, a declinable part of speech, which being put instead of a noun, points out some person or thing.

PROOF, the shewing or making plain the truth of any matter alleged; either in giving evidence to a jury on a trial, or else on interrogatories or by copies of records, or exemplifications of them. See EVIDENCE.

PROOF *of artillery and small arms*, is a trial whether they stand the quantity of powder allotted for that purpose. The rule of the board of ordnance is, that all guns under 24-pounders are loaded with powder as much as their shot weighs; that is, a brass 24-pounder with 21 lb. a brass 32-pounder with 26 lb. 12 oz. and a 42-pounder with 31 lb. 8 oz. the iron 24-pounder with 18 lb. the 32-pounder with 21 lb. 8 oz. and the 42-pounder with 25 lb.

The brass light field-pieces are proved with powder that weighs half as much as their shot, except the 24-pounder, which is loaded with 10 lb. only.

Government allows 11 bullets of lead in the pound for the proof of muskets; and 14.5, or twenty-nine in two, for service; seventeen in the pound for the proof of carbines, and twenty for service; twenty-eight in the pound for the proof of pistols, and thirty-four for service.

When guns of a new metal, or of lighter construction, are proved; then, besides the common proof, they are fired 200 or 300 times, as quick as they can be loaded with the common charge given in actual service. Our light six-pounders were fired 300 times in three hours and twenty-seven minutes, loaded with 1 lb. 4 oz., without receiving any damage.

PROOF *of powder*, is in order to try its goodness and strength. See GUNPOWDER.

PROOF *of cannon*, is made to ascertain their being well cast, their having no cavities in the metal, and in a word, their being fit to resist the effort of their charge of powder. In making this proof, the piece is laid upon the ground, supported only by a piece of wood in the middle, of about five or six inches thick, to raise the muzzle a little, and then the piece is fired against a solid butt of earth.

Proof *of mortars and howitzers,* is made to ascertain their being well cast, and of strength to resist the effort of their charge. For this purpose the mortar or howitzer is placed upon the ground, with some part of the trunnions or breech sunk below the surface, and resting on wooden billets at an elevation of about seventy degrees. The mirror is generally the only instrument to discover the defects in mortars and howitzers. In order to use it, the sun must shine; the breech must be placed towards the sun, and the glass over-against the mouth of the piece which illuminates the bore and chamber sufficiently to discover the flaws in it.

Proof *of foreign brass artillery.* 1st, The Prussians. Their battering-train and garrison artillery are proved with a quantity of powder equal to half the weight of the shot, and fired seventy-five rounds as fast as in real service; that is, two or three rounds in a minute. Their light field-train, from a 12-pounder upwards, are proved with a quantity of powder = 1-3d of the weight of the shot, and fired 150 rounds, at three or four rounds in a minute. From a 12-pounder downwards, are proved with a quantity = 1-5th of the shot's weight, and fired 300 rounds, at five or six rounds each minute, properly spunged and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible. 2d, The Dutch prove all their artillery by firing each piece five times: the two first rounds with a quantity of powder = 2-3ds of the weight of the shot; and the three last rounds with a quantity of powder = half the weight of the shot. 3d, The French the same as the Dutch.

Proof, in brandy and other spirituous liquors, is a little white froth which appears on the top of the liquor when poured into a glass. This froth, as it diminishes, forms itself into a circle called by the French the chapelet, and by the English the bead or bubble.

PROPOLIS. See Resins.

PROPORTION, in arithmetic, &c. See Algebra, p. 54.

Proportion is often confounded with ratio; but they are quite different things. For, ratio is properly the relation of two magnitudes or quantities of one and the same kind; as the ratio of 4 to 8, or of 15 to 30, or of 1 to 2 and so implies or respects only two terms or things. But proportion respects four terms or things, or two ratios which have each two terms; though the middle term may be common to both ratios, and then the proportion is expressed by three terms only, as 4, 8, 64, where 4 is to 8 as 8 to 64.

Proportion is also sometimes confounded with progression. In fact, the two often coincide; the difference between them only consisting in this, that progression is a particular species of proportion, being indeed a continued proportion, or such as has all the terms in the same ratio, viz. the 1st to the 2d, the 2d to the 3d, the 3d to the 4th, &c; as the terms 2, 4, 8, 16, &c. so that progression is a series or continuation of proportions. See Progression.

Proportion is either continual, or discrete, or interrupted.

The proportion is continual when every two adjacent terms have the same ratio, or when the consequent of each ratio is the antecedent of the next following ratio, and so all the terms form a progression: as 2, 4, 8, 16, &c.; where 2 is to 4 as 4 to 8, and as 8 to 16, &c.

Discrete or interrupted proportion, is when the consequent of the first ratio is different from the antecedent of the 2d, &c.; as 2, 4, and 3, 6.

Proportion is also either direct or inverse.

Direct proportion is when more requires more, or less requires less; as it will require more men to perform more work, or fewer men for less work, in the same time.

Inverse or reciprocal proportion, is when more requires less, or less requires more. As it will require more men to perform the same work in less time, or fewer men in more time. Ex. If 6 men can perform a piece of work in 15 days, how many men can do the same in 10 days? Then,

reciprocally as $\frac{1}{15}$ to $\frac{1}{10}$ so is $6 : 9$ } the an-
or inversely as 10 to 15 so is $6 : 9$ } swer.

Proportion, again, is distinguished into arithmetical, geometrical, and harmonical.

Arithmetical proportion is the equality of two arithmetical ratios, or differences: as in the numbers 12, 9, 6; where the difference between 12 and 9, is the same as the difference between 9 and 6, viz. 3.

And here the sum of the extreme terms is equal to the sum of the means, or to double the single mean when there is but one. As $12 + 6 = 9 + 9 = 18$.

Geometrical proportion is the equality between two geometrical ratios, or between the quotients of the terms. As in the three 9, 6, 4, where 9 is to 6 as 6 is to 4, thus denoted $9 : 6 :: 6 : 4$; for $\frac{9}{6} = \frac{6}{4}$, being each equal $\frac{2}{3}$ or $1\frac{1}{2}$.

And in this proportion, the rectangle or product of the extreme terms, is equal to that of the two means, or the square of the single mean when there is but one. For $9 \times 4 = 6 \times 6 = 36$.

Harmonical proportion, is when the first term is to the third, as the difference between the 1st and 2d is to the difference between the 2d and 3d; or in four terms, when the 1st is to the 4th, as the difference between the 1st and 2d is to the difference between the 3d and 4th; or the reciprocals of an arithmetical proportion are in harmonical proportion. As 6, 4, 3; because $6 : 3 :: 6 - 4 = 2 : 4 - 3 = 1$ or because $\frac{1}{5}, \frac{1}{4}, \frac{1}{3}$, are in arithmetical proportion, making $\frac{1}{6} + \frac{1}{3} = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}$. Also the four 24, 16, 12, 9, are in harmonical proportion, because $24 : 9 :: 8 : 3$.

PROPORTIONAL *compasses*, are compasses with two pair of opposite legs, like a St. Andrew's cross, by which any space is enlarged or diminished in any proportion.

Proportional *scales*, called also logarithmic scales, are the logarithms, or artificial numbers, placed on lines, for the ease and advantage of multiplying and dividing, &c. by means of compasses, or of sliding rulers. These are in effect so many lines of numbers, as they are called by Gunter, but made single, double, triple, or quadruple; beyond which they seldom go.

PROPORTIONALS, are the terms of a proportion: consisting of two extremes, which are the first and last terms of the set, and the means, which are the rest of the terms. These proportionals may be either arithmeticals, geometricals, or harmonicals, and in any number above two, and also either continued or discontinued.

Pappus gives this beautiful and simple comparison of the three kinds of proportionals, arithmetical, geometrical, and harmonical, viz. a, b, c, being the first, second, and third terms in any such proportion, then

In the arithmeticals, $a : a$ }
in the geometricals, $a : b$ } $:: a - b : b - c$.
in the harmonicals, $a : c$ }

Continued proportionals form what is called a progression. See Progression.

I. *Properties of arithmetical proportionals.*

For what respects progressions and mean proportionals of all sorts, see Mean and Progression.

1. Four arithmetical proportions, as 2, 3, 4, 5, are still proportionals when inversely 5, 4, 3, 2; or alternately, thus, - 2, 4, 3, 5; or inversely and alternately, thus, 5, 3, 4, 2.

2. If two arithmeticals are added to the like terms of other two arithmeticals, of the same difference or arithmetical ratio, the sums will have double the same difference or arithmetical ratio.

So, to	3 and 5, whose difference is	2,
add	7 and 9, whose difference is also	2,
the sums	10 and 14 have a double diff. viz.	4.

And if to these sums are added two other numbers also in the same difference, the next sums will have a triple ratio or difference; and so on. Also, whatever are the ratios of the terms that are added, whether the same or different, the sums of the terms will have such arithmetical ratio as is composed of the sums of the others that are added.

So	3 ,	5, whose diff. is	2
and	7 ,	10, whose diff. is	3
and	12 ,	16, whose diff. is	4
	—	—	—
make	22 ,	31, whose diff. is	9.

On the contrary, if from two arithmeticals are subtracted others, the difference will have such arithmetical ratio as is equal to the differences of those.

So from	12 and	16, whose dif. is	4
take	7 and	10, whose dif. is	3
	—	—	—
leaves	5 and	6, whose dif. is	1
	—	—	—
Also from	7 and	9, whose dif. is	2
take	3 and	5, whose dif. is	2
	—	—	—
leaves	4 and	4, whose dif. is	0

Hence, if arithmetical proportionals are multiplied or divided by the same number, their difference, or arithmetical ratio, is also multiplied or divided by the same number.

II. *Properties of geometrical proportionals.*

The properties relating to mean proportionals are given under the term Mean Proportional; some are also given under the article Proportion; and some additional ones are as below:

1. To find a 3d proportional to two given numbers, or a 4th proportional to three, in the former case, multiply the 2d term by itself, and divide the product by the 1st; and in the latter case, multiply the 2d term by the 3d, and divide the product by the 1st.

So $2 : 6 :: 6 : 18$, the 3d prop. to 2 and 6:
and $2 : 6 :: 5 : 15$, the 4th prop. to 2, 6, and 5.

2. If the terms of any geometrical ratio are augmented or diminished by any others in the same ratio, or proportion, the sums or differences will still be in the same ratio or proportion.

So if $a : b :: c : d$,
then is $a : b :: a \pm c : b \pm d :: c : d$.

And if the terms of a ratio, or proportion, are multiplied or divided by any one and the same number, the products and quotients will still be in the same ratio, or proportion.

Thus, $a : b :: na : nb :: \frac{a}{n} : \frac{b}{n}$.

3. If a set of continued proportionals are either augmented or diminished by the same part or parts of themselves, the sums or differences will also be proportionals.

Thus if a, b, c, d, &c. are propors. then are $a \pm \frac{a}{n}$, $b, \pm \frac{b}{n}$, $c, \pm \frac{c}{n}$, &c. also proportionals, where the common ratio is $1 \pm \frac{1}{n}$.

And if any single quantity is either augmented or diminished by some part of itself, and the result is also increased or diminished by the same part of itself, and this third quantity treated in the same manner, and so on; then shall all these quantities be continued proportionals. So, beginning with the quantity a, and taking always the nth part, then shall

a, $a \pm \frac{a}{n}$, $\pm \frac{2a}{n} + \frac{a^2}{n^2}$, &c. be proportionals, or a, $a \pm \frac{a}{n}$, $(a \pm \frac{a}{n})^2$, $(a \pm \frac{a}{n})$, &c. proportionals the common ratio being $1 \pm \frac{a}{n}$.

4. If one set of proportionals is multiplied or divided by any other set of proportionals, each term by each, the products or quotients will also be proportionals.

Thus, if $a : na :: b : nb$,
and $c : mc :: d : md$;
then is $ac : mnac :: bd : mnbd$,
and $\frac{a}{c} : \frac{na}{mc} :: \frac{b}{d} : \frac{nb}{mb}$.

5. If there are several continued proportionals, then whatever ratio the 1st has to the 2d, the 1st to the 3d shall have the duplicate of the ratio, the 1st to the 4th the triplicate of it, and so on.

So in a, na, n^2a, n^3a, &c. the ratio being n;
then $a : n^2a$, or 1 to n^2, the duplicate ratio,
and $a : n^3a$, or 1 to n^2, the triplicate ratio,
and so on.

6. In three continued proportionals, the difference between the 1st and 2d term, is a mean proportional between the 1st term and the second difference of all the terms.

Thus, in the three propor. a, na, n^2a;

Terms	1st difs.	2d dif.
n^2a		
na	$n^2a - na$	
a	$na - a$	$n^2a - 2na + a$,

then $a : na - a :: na - a : n^2a - 2na + a$.

Or in the numbers 2, 6, 18;

18		
6	12	8 the 2d difference;
2	4	

then 2, 4, 8 are proportionals.

7. When four quantities are in proportion, they are also in proportion by inversion, composition, division, &c.; thus, a, na, b, nb, being in proportion, viz.

1.	$a : na :: b : nb$; then by	
2. Inversion	$na : a :: nb : b$;	
3. Alternation	$a : b :: na : nb$;	
4. Composition	$a + na : na :: b + nb : nb$;	
5. Conversion	$a + na : a :: b + nb : b$;	
6. Division	$a - na : a :: b - nb : b$;	
	$a - na : na :: b - nb : nb$;	

III. *Properties of harmonical proportionals.*

1. If three or four numbers in harmonical proportion, are either multiplied or divided by any number, the products or quotients will also be harmonical proportions.

Thus, 6, 3, 2, being harmon. propor.
then 12, 6, 4, are also harmon. propor.
and $\frac{6}{2}$, $\frac{3}{2}$, $\frac{2}{2}$ are also harmon. propor.

2. In the three harmonical proportionals, a, b, c, when any two of these are given, the third can be found from the definition of them, viz. that $a : c :: a - b : b - c$; for hence

$b = \frac{2ac}{a + c}$ the harmonical mean and

$c = \frac{ab}{2a - b}$ the third harmon. to a and b.

3. And of the four harmonicals, a, b, c, d, any three being given, the fourth can be found from the definition of them, viz. that $a : d :: a - b : c - d$; for thence the three b, c, d, will be thus found, viz.

$b = \frac{2ad - ac}{d}$; $c = \frac{2ad - bd}{a}$; $d = \frac{ab}{2a - b}$.

4. If there are four numbers disposed in order, as 2, 3, 4, 6, of which one extreme and the two middle terms are in arithmetical proportion, and the other extreme and the same middle terms are in harmonical proportion; then are the four terms in geometrical proportion: so here

the three 2, 3, 4 are arithmeticals,
and the three 3, 4, 6 are harmonicals,
then the four 2, 3, 4, 6 are geometricals.

5. If between any two numbers, as 2 and 6, there are interposed an arithmetical mean 4, and also a harmonical mean 3, the four will then be geometricals, viz. $2 : 3 :: 4 : 6$.

6. Between the three kinds of proportion, there is this remarkable difference viz. that from any given number there can be raised a continued arithmetical series increasing ad infinitum, but not decreasing; while the harmonical can be decreased ad infinitum, but not increased; and the geometrical admits of both.

PROPORTIONS of the human body. See DRAWING.

PROPORTIONS of the antique statues. See STATUES, and SCULPTURE.

PROPOSITION, in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject; or according to Chauvinus, it is a complete consistent sentence, indicating or expressing something either true or false, without ambiguity; as, God is just.

PROPOSITION, in mathematics, is either some truth advanced and shewn to be such by demonstration, or some operation proposed and its solution shewn. If the proposition is deduced from several theoretical definitions compared together, it is called a theorem; if from a praxis, or series of operations, it is called a problem.

PROSERPINACA, a genus of the trigynia order, in the triandria class of plants; and in the natural method ranking under the 15th order, inundatæ. The calyx is tripartite superior; there is no corolla; there is one trilocular seed. There is one species, a marsh plant of Virginia.

PROSODY, that part of grammar which treats of the quantities and accents of syllables, and the manner of making verses.

PROSOPIS, a genus of the monogynia order, in the decandria class of plants. The calyx is hemispherical and quadridentate; the stigma is simple, the legumen inflated and monospermous. There is one species, a tree of the East Indies.

PROSOPOPŒIA, a figure in rhetoric, whereby we raise qualities, or things inanimate, into persons. See RHETORIC.

PROSTATÆ. See ANATOMY.

PROSTYLE, in antient architecture, a range of columns in front of a temple.

PROTEST, when one openly affirms, that he does either not at all, or but conditionally, yield his consent to any act, or unto the proceeding of a judge in court wherein his jurisdiction is doubtful, or to answer upon his oath any farther than by law he is bound.

PROTEST, is also that act by which the holder of a foreign bill of exchange declares that such bill is dishonoured.

PROTEST, is also that act of a master, on his arrival with his ship from parts beyond the seas, to save him and his owners harmless and indemnified from any damage sustained in the goods of her lading, on account of storms. See BILLS OF EXCHANGE, and INSURANCE.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529, they protested against a decree of the emperor Charles V. and the diet of Spires; declaring that they appealed to a general council. The same name also has been given to those of the sentiments of Calvin, and is now become a common denomination for all those of the reformed churches.

PROTEA, the *silver-tree*, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. There is one quadrifid petal surrounding the germ; there is no proper calyx; the receptacle is paleaceous. There are sixty-four species, chiefly natives of the Cape of Good Hope; of which the most remarkable are, 1. The conifera, with linear, spear-shaped, entire leaves, grows to the height of ten or twelve feet, with a straight regular stem. The branches naturally form a large regular head. The leaves are long and narrow, of a shining silver-colour, and, as they remain the whole year, make a fine appearance in the greenhouse. 2. The argentea, commonly called silver-tree, has a strong upright stem covered with purplish bark, dividing into several branches which grow erect, with broad, shining, silvery, leaves, which make a fine appearance when intermixed with other exotics. Through the whole year it exhibits its glossy white or silvery leaves. It has at first a very uncommon and beautiful appearance; and sometimes in the course of twelve or fifteen years, reaches the height of twenty feet, which it never exceeds. In a rich soil it grows twice as quick, and is by far the largest of the protea kind. They are generally planted near some farms, and very seldom grow wild; Mr. Sparrman thinks it was probably brought to the Cape of Good Hope from Anamaqua; for he had travelled over the whole north-east side of Hottentots' Holland, without finding it either in its wild state or planted. 3. The nitida, or wageboom, greatly resembles the second sort; the leaves are very silky and white, with erect purple branches.

All these plants being tender exotics, require to be continually kept in the greenhouse during winter. The first may be propagated by cuttings, which should be cut off in April, just before the plants begin to shoot; the second and third sorts may be propagated by seeds.

PROTHONOTARY, a term which properly signifies first notary, and which was antiently the title of the principal notaries of the emperors of Constantinople.

Prothonotary with us is used for an officer, in the courts of king's bench and common pleas; the former of which courts has one, and the latter three. The prothonotary of the king's bench, records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the common pleas enter and inrol all declarations, pleadings, assizes, judgments and actions; they also make out all judicial writs, except writs of habeas-corpus, and distringas jurator, for which there is a particular office, called the habeas corpora office; they likewise enter recognizances acknowledged, and all common recoveries; make exemplifications of records, &c.

PROTOXIDE, in chemistry, a term used to denote the minimum of oxidizement. See OXIDE.

PROTRACTION, the same with plotting. See SURVEYING.

PROTRACTOR, the name of an instrument used for protracting or laying down on paper the angles of a field, or other figure. See INSTRUMENT.

PROVISO, in law, a condition inserted in a deed, upon the observance whereof the validity of the deed depends.

PROVOST, an officer, whereof there are divers kinds, civil, military, &c.

PROVOST of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Glasgow, &c. being much the same with mayor in other places He presides in city-courts, and, together with the baillies, who are his deputies, determines in all differences that arise among citizens.

PROVOST *marshal of an army*, is an officer appointed to seize and secure deserters, and all other criminals. He is to hinder soldiers from pillaging, to indict offenders, and see the sentence passed on them executed. He also regulates the weights and measures, and the price of provisions, &c. in the army. For the discharge of his office, he has a lieutenant, a clerk, and a troop of marshalmen on horseback, as also an executioner. There is also a provost marshal in the navy, who has charge over prisoners, &c.

PROW, in navigation, denotes the head or fore part of a ship, particularly in a galley, being that which is opposite the poop or stern.

PRUNELLA, self-hue, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 12th order, holoraceæ. The filaments are bifurcated, with an anthera only on one point; the stigma is bifid. There are three species, herbs of Europe.

PRUNELLÆ *sal*, in pharmacy, a preparation of purified saltpetre.

PRUNES, in commerce, are plums dried in the sunshine, or in an oven.

PRUNING *wall-trees*. Of this "master work of gardening," it has been said, "that gentlemen prune too little, and gardeners too much;" these extremes are to be avoided, as attended with peculiar evils, equally mischievous: wall-trees are presently spoiled by either practice. If they are too full of wood, the shoots and fruits cannot be properly ripened: and if they are too thin (the greater evil of the two), the consequence of the cutting that has made them so, is the production of wood rather than fruit; forcing out shoots, where otherwise blossom-buds would have been formed. The designation of trees to a wall (from the superabundant heat) necessarily occasions cutting, and on the skilful use of the knife much depends.

Every one who has wall-trees cannot keep a professed gardener; nor is every one who calls himself so, qualified to prune. It is a great mortification to a man who wishes to see his trees in order, not to be able to procure an operator to attend them; let him then resolve to learn the art himself, and the ability will be very gratifying to him.

As many words must be used on this article of pruning, for the sake of order, the business of managing wall-trees may be, 1. Concerning the form. 2. The health. 3. The fruitfulness of them.

1. As to the form, or general appearances of the wall-trees. If a tree is young and newly planted, the first thing is to head it down, by cutting off (if it is a nectarine, peach, or apricot) all the shoots, and the stem itself, down to a few eyes, that the lower part of the wall may be furnished with new and strong wood. Make the cut sloping, and behind the tree, taking care (by placing the foot on the root, and the left hand on the stem) not to disturb the tree by the pull of the knife. Plaster the part with a bit of cow-dung, clay, or stiff earth. It is evident from this that maiden stocks are the best to plant.

The heading down is to be made so as to leave two or three eyes, or four if a high wall, on each side of the stem, from which shoots will come properly placed for training. The number of eyes may be also according to the strength of the tree, and its roots If there are not two well-placed eyes on each side of the stem, two shoots, thus situated, may be left, cutting them short to two or three eyes each. Eyes or shoots behind or before, consider as of no use, and let them be early displaced by rubbing or cutting. This work is to be performed in spring, when the tree is putting forth shoots; *i. e.* about the beginning of April.

If towards the end of May there should be wanting shoots on either side the tree, having perhaps only one put forth where two were expected, this one shoot should be cut, or pinched down, to two or three eyes; and before summer is over there will be found good shoots from them, and thus a proper head be obtained. This work of shortening shoots of the year may be done any time before Midsummer; but in this case, all ill-placed or superfluous growths must be rubbed off as soon as seen, that those to be reserved may be the stronger, receiving more nourishment.

As the lateral shoots grow, let them be timely nailed to the wall, close, straight, and equidistant, but use no force. If they are quite well placed, they will need no bending; but sometimes shoots must be laid in which are not perfectly so. Lay in as many good moderate-sized shoots as may be throughout the summer, for choice at winter pruning, yet do not crowd the tree. As the shoots proceed in length, nail them to the wall, that no material dangling of them may be seen; but avoid using too many shreds.

In the formation of a tree, keep each side as nearly as can be equal in wood; and the shoots inclining downwards, which is a mode of training necessary to fill the lower part of the wall (none of which should be lost), and to check the too free motion of the sap, which wall-trees are liable to from their warm situation and continual cutting. All the branches should have an horizontal tendency, though the upper cannot have it so much as the lower ones. Those that are perpendicular, or nearly so, mount the wall too fast, and run away with the food that should pass to the horizontals; which being impoverished by the vigorous middle branches, gradually become too weak to extend themselves, and nourish the fruit. The pruner, therefore, must be content to have some of the wall, over the middle of the tree, unoccupied; or, at least, suffer none but weak or very moderate shoots to find a place there.

The idea of a well-formed tree is somewhat represented by the ribs of a spread fan, or the fingers of the hand extended. Regularity is allowed to be so necessary to the beauty of a wall-tree, that some have even drawn lines for a guide to train by; but nature (ever free and easy) will not submit to so much formality, and such a perfect disposition of the branches is not necessary. A tree may be regular without being linear, and the proper useful shoots are not to be sacrificed to a fanciful precision. Though crossing of branches is against rule, yet cases may happen (as in want of wood or fruit) where even this awkwardness may be permitted. The object is fruit; and to obtain this end, form must sometimes give place.

All foreright and back shoots, and other useless wood, should be displaced in time, for they exhaust the strength of the tree to no purpose, and occasion a rude appearance. It is a very expeditious method to displace superfluous young shoots, by pushing or breaking them off; but when they get woody it is apt to tear the bark, and in this case the knife must be used: the better way is to disbud by rubbing; yet a young luxuriant tree should be suffered to grow a little wild to spend the sap. There is one evil, however, attending on disbudding, and rubbing off young forerights, that some fruit spurs are thus lost; for apricots are apt to bear on little short shoots of from half an inch to an inch (or more), and there are peaches which do the same; so that it is a rule with some pruners to wait to distinguish spurs from shoots, and then to use the knife, yet use it as little as may be in summer.

In regulating a tree at any time, begin at the bottom and middle, and work the way orderly upward and outward. Never shorten in summer (which would produce fresh shoots), except a forward shoot where wood may be wanting; but where the tree is really too thick, cut clean out what may be spared. None of the shoots produced after midsummer should be nailed in, except where wood is wanting to fill a naked place. They never bear fruit.

2. The health of wall-trees is greatly provided for by observing the directions already given concerning their form; for if observed, each shoot will have the proper benefit of sun and air, to concoct its juices and prepare it for fruiting.

It injures a tender shoot when it presses hard against a nail. If the hammer strikes a shoot, and bruises the bark, it often spoils if not kills it, by the part cankering. The shreds may be too tight, so that the shoot cannot properly swell; and if shreds are too broad and too numerous, they are apt to occasion sickness, and prove a harbour for insects and filth: let the number be lessened at all opportunities. A slip of the knife may wound a neighbouring branch, and make it gum, canker, or die. It will require care, and some practice, to avoid this accident; and in order to it, keep the point of the knife sharp, and mind the position of it when cutting. Cut close and sloping behind the eye; neither so near as to injure it, nor so wide as to leave a stub.

The bending of a branch much is a violence to be avoided; so that every shoot should be kept from the first in the direction it is to grow in.

Luxuriant wood must be particularly attended to, to get rid of it in time, before it has robbed the weaker branches too much. That is luxuriant wood which, according to the general habit of the tree, is much larger than the rest; for a shoot that is deemed luxuriant in one tree may not be so in another. If strong wood, that is not very luxuriant, happens to be at the bottom of the tree, so that it can be trained quite horizontally, it may often be used to good purpose, as this position checks the sap. A luxuriant shoot may be kept in summer where it is not designed to retain it, merely to cut it down at winter-pruning to two or three eyes, for getting wood where wanted the next year; or this shortening may take place in June, to have new shoots the present year. Luxuriant shoots may be sometimes retained for a time, merely as waste pipes.

All diseased, damaged, very weak, or worn out branches (as they occur), should be cut out, to make way for better; but if a tree is generally diseased, some caution must be used not to cut out too much at once, if there is any hope of restoring it. A very old tree, or a young one that does not thrive, may be cut a great deal; but prune it so as to have a general sprinkling of the best of the branches, and keep short lengths of an eye or two of the weaker ones, in a sort of alternate order.

Young trees are very apt to decline, and sometimes die, if suffered to overbear themselves the first year or two of fruiting. The remedy is obvious, and should resolutely be applied.

A weak tree is helped much by training it more erectly than usual, as less check is thus given to the sap, and so the shoots are more likely to swell: such a tree should be kept thin of branches, and always pruned early in autumn, keeping the top free from such wood as is stronger than that which is in general below, and all the shoots shorter than usual.

Old decaying trees should be lessened a little every year, and constantly watched, to observe where young and strong shoots are putting out below, in order to cut down to them; and though the time for doing this is commonly at autumn or winter pruning, yet it may be best done in summer, as the shoots would thrive the better; observing to put some grafting-clay or cow-dung to the part, to prevent gumming, which summer pruning is apt to occasion. A judicious pruner may bring the oldest and most ill-conditioned tree to a healthy and bearing state if all is but right at the root, it having a good soil about it.

Keep all wall-trees clean, and particularly weak ones, from moss, cobwebs, or other filth; and attend to insects, snails, caterpillars, and smother flies. Any bark that is decayed by cracks, &c. must be cleared away to the quick, either by rubbing, or the knife, as filth and insects are apt particularly to gather there: wipe the part clean with spunge and soap.

Consider the soil about an unthrifty tree, and if it is thought bad, improve it by moving away as much of the old as conveniently can be done. The roots may be laid carefully quite bare, and examined, in order to cut off decayed or cankered parts, and to apply immediately to them some fine and good fresh earth, with a little thorough-rotten dung in it, and a sprinkling of soot or wood ashes. Hog-dung applied fresh is said to have a peculiar efficacy in recovering weak trees; and cow-dung may reasonably be expected to do good if the soil is a warm or hungry one; and if not so, the hog-dung is not so proper, as it is a cold dressing. If the soil is a strong one, a compost of fowl's or sheep's dung, lime, with any fresh light earth, (one part of each of the former, and three of the latter, mixed with the soil that is taken off,) will be a proper manure, to which a little sharp sand may be added. All these applications should be made late in autumn, or early in spring.

The constitution of a tree is sometimes naturally barren; or the soil that the roots have got into may be so deleterious that no pains or perseverance will avail any thing; but continuing fruitless and sickly, admonishes the owner to take it up and try another plant, rectifying the soil thoroughly if the evil is thought to arise there. The smother-fly sometimes repeatedly attacks the same tree, which is a sign of inherent weakness, for the juices of a sickly tree are sweeter than those of a sound one, and so more liable to such attacks. Sometimes a tree of this kind, when removed to a good soil, and pruned greatly down, does very well. A soil too rich of dung often occasions trees to be blighted, and the remedy is to impoverish it with a sharp sand.

In order to health and strength, a tree must not be kept too full during summer, as it prevents the proper ripening of the wood, and makes the shoots long-jointed. If more than one shoot proceeds from the same eye, reserve only the strongest and best-situated. A crowded tree cannot be healthy, and it becomes both lodging and food for insects. The blossom-buds of a tree being always formed the year before, they will be few and weak in a thicket of leaves, as debarred of the necessary sun and air; but in order to avoid an over-fulness, do not make any great amputations in summer.

In clearing a tree of superabundant wood, take care not to cut off the leading shoot of a branch. All shoots after midsummer should be displaced as they arise, except where wanted to fill up a vacancy. In a too vigorous tree, the midsummer shoots may be left for a while on those branches that are to be cut out at winter pruning, as cutting such trees in summer is to be avoided as much as possible; so that a little rudeness in a luxuriant tree may be permitted as a necessary evil, provided it becomes not too shady or unsightly. Watering wall-trees with an engine smartly on a summer's evening is conducive to their health, and frees them from insects.

3. The fruitfulness of wall-trees (the ultimate object of planting and training them) comes now to be spoken of. Their proper form and health being good, the foundation is laid, but several things are yet to be done to obtain the end proposed; and this chiefly regards the principal cutting, or what is called winter or spring pruning.

If trees have been planted far enough asunder, it is a happy circumstance, as the proper horizontal form, and the open middle, may be preserved. The longer the horizontals are, the more necessary it is to be careful to suffer none but weak branches in the centre uprightly. If trees are confined as to length of wall, they of course take a more erect form, but still strong wood should not mount just in the middle.

A tree is to be thinned of damaged, unpromising, and ill-placed shoots, and of woody branches that are decaying or reach far without fruitful shoots on them, and always some of the old wood should be cut out where there is young to follow or supply its place. Of the fair and well-placed shoots also, the superabundance is to be taken away, so as generally to leave the good ones at four, five, or six inches asunder, according to the size of the wood and fruit.

Luxuriant wood, *i. e.* those shoots that are gigantic, must be taken out from the rest, as they would impoverish the good, and destroy the weak branches, and are never fruitful; but if a tree is generally luxuriant it must be borne with; and the less it is cut, comparatively speaking, the better. Such a tree, after a few years, may come to bear well; and when it begins to shoot moderately, some of the largest wood may be taken out each year, or shortened down to two or three eyes, and so brought into order. The more horizontally free-shooting trees are trained, the better, as the bending of the shoots checks the sap.

As the pruner is to begin below, and towards the stem, so the object in thinning must be to prefer and to leave those shoots that are placed lowest on the branches, that so the tree may be furnished towards the centre. See that those left are sound, and not too weak or over-strong, for the moderate shoots generally bear best. Weak shoots are always more fruitful than strong ones; and if they are furnished with fair blossoms, should be kept where a tree is full of wood, and even preferred to moderate ones on a very flourishing tree.

The next object is, to furnish a tree. In order to this, the thinning of old wood, young being ready (or easily to be procured) to follow, has already been mentioned; but the principal step is the shortening of the shoots, which occasions them to throw out below the cut, for future use. If they were not to be shortened, the tree would presently extend a great way, bearing chiefly at the extremities; and all over the middle it would be very thin of fruit, and thus a great part of the wall lost.

The mode of bearing in peaches, nectarines, and apricots, is on the last year's wood; which makes it necessary to shorten, in order to a certain supply of shoots for bearing the next year, and thus to have succession-wood in every part of the tree.

The rule for shortening is this: Consider the strength of the tree; and the more vigorous the shoots are, cut off the less. If a luxuriant tree was to have its shoots much shortened, it would throw out nothing but wood; and if a weak tree was not pretty much cut, it would not have strength to bear. From vigorous shoots one-fourth may be cut off; from middling ones one-third; and from weak ones one-half.

In shortening, make the cut at a leading shoot-bud, which is known by having a blossom-bud on the side of it, or, which is better, one on each side. Blossom-buds are rounder and fuller than leaf-buds, and are discernible even at the fall of the leaf, and plainly seen early in the spring. It is desirable to make the cut at twin blossoms, yet as this cannot always be done, the due proportion of length must generally determine. It often happens, that the blossom-buds are chiefly, and sometimes all, at the end of the shoot; but still it should be shortened if it is at all long. Never cut where there is only a blossom-bud; and prefer those shoots that are shortest-jointed, and have the blossoms most in the middle. The shoots that lie well and are fruitful or healthy, and but a few inches long, may be left whole. Always contrive to have a good leader at the end of every principal branch.

Young trees (as of the first year of branching) should have the lower shoots left longer in proportion, and the upper shorter, in order to form the tree better to the filling of the wall: the lower shoots may have three or four eyes more than the upper.

In furnishing a tree, consider where it wants wood, and cut the nearest unbearing branch (or if necessary, a bearing one) down to one, two, or more eyes, according to the number of shoots desired, for in such close shortening, a shoot will come from each eye. With a view to wood for filling up a naked place, a shoot formed after midsummer may be thus shortened; though the general rule is, to displace all such late shoots as useless, the dependance for blossoms being on the early-formed shoots.

The time for the principal, or winter pruning, is by some gardeners held indifferent, if the weather is mild at the time; but a moderate winter's day is often quickly followed by a severe frost, which may hurt the eye and blossom next the cut. The best time is February, if it is mild, or as soon after as possible; for when the blossom-buds get swelled, they are apt to be knocked off by a little touch or jar of the hammer.

Apricots should not be so much shortened as peaches, nor do they so well endure the knife. Shoots of the apricot, if under a foot, may be left uncut, if there is room. The spurs of apricots should be spared, if not too long or numerous, for they bear well, and continue for years. Some sorts of peaches are also apt to put out fruit-spurs, and must be managed accordingly.

Vines require frequent attention, as to pruning and training; but all will avail little if they have not a warm soil and full sun, or some accidental advantage, as being planted at the back of a warm chimney; and though they will grow and bear leaves any where, they will not fruit well in England without a favourable season, or hot summer.

Young new-planted vines should be pruned quite short for two or three years, that they may get strong. If the plant has a weak root, not above one shoot ought to grow the first year, which should be cut down in autumn, or to two or three eyes.

The best time for the principal, or winter pruning of vines, is as soon as the fruit is off, or the leaves falling. November does very well, and if this month passes, February should be adopted rather than quite in the winter. Late in the spring they are apt to bleed by cutting, which greatly weakens them.

The mode of bearing in vines is only on shoots of the present year, proceeding from year-old wood. The rule, therefore, at winter pruning is, to reserve those shoots of the year that are best situated as to room, for training of those shoots that are to come from them, which will be almost one from every eye. Make choice of those that are placed most towards the middle, or stem of the vine, that all the wall may be covered with bearing wood; and every year cut some old wood out that reaches far, to make room for younger to follow.

The shortening of the shoots should be according to their strength, and the space there is for training those shoots that will be produced, which always grow very long. If there is room, three, four, or five eyes may be left; but not more to any shoot, except it is desirable to extend some shoot to a distance to fill up a particular space: and then eight or nine eyes may be left, which being repeated again another year, and so on, a vine will soon reach far.

Sometimes vines are trained on low walls by a long-extended horizontal branch, a few inches from the ground, as a mother-bearer. Those shoots that come from this horizontal are to be trained perpendicularly, and cut down to one or two eyes every year, that they may not encroach too fast on the space above them. If the vine is confined to a narrow but lofty space, it is to be trained to an extended perpendicular mother-bearer, having short lateral shoots pruned down to a single eye, or at most two. The management of vines requires severe cutting, that they may not be too full in the summer, for they put out a great deal of wood, and extend their shoots to a great length; and therefore the young pruner must resolve to cut out enough.

An alternate mode of pruning vines is practised by some, one shoot short, and another long, *i. e.* one with two eyes, and another with four or five. Severe cutting does not hurt vines, and make them unfruitful, as it does other trees; and therefore, where short of room, they may be pruned down to a single bud, as the case requires.

The summer management of vines must be carefully attended to. As soon as the young shoots can be nailed to the wall, let them not be neglected; but remember they are very tender, and will not bear much bending: train in only the well-placed shoots, rubbing or breaking off the others. The embryo fruit is soon seen in the bosom of the shoot; and those thus furnished are of course to be laid in, as many as can be found room for, in preference to those shoots that are barren; which nevertheless should also be trained, if they are strong and well placed, and there is space for them. Rub off all shoots from old wood, except any tolerable one that proceeds from a part where wood is wanting to fill up some vacant space. If two shoots proceed from one eye, displace the weakest, or the outermost if they are both alike, and the fruit should not direct otherwise. Vines grow rapidly; and must be nailed to the wall, from time to time, as they proceed, that there may be no rude dangling, which would not only have a slovenly appearance, but in several respects be injurious.

The stopping of the shoots is to take place, both as to time and measure, according to the strength and situation of them, or whether fruitful or barren. Those weak shoots that have fruit, and are rather ill placed, or confined for room, may be stopped at the second, or even first, joint above the fruit, early in the summer; but those shoots that are strong and have room to grow, should not be stopped till they are in flower (in July), and at the third or fourth joint above the fruit. In shortening the shoots of the vine, do it about half an inch above an eye, sloping behind a plump and sound one. The barren shoots are to be trained at full length, and not stopped at all if there is room for them, or, at least, but a little shortened towards autumn, as in August, because they would put out a number of useless and strong side-shoots if cut before.

The side-shoots, *i. e.* those little ones put out by the eyes that are formed for next year, are commonly directed to be immediately displaced by rubbing off, as soon as they appear; and if the vine is large, and the shoots slender, it is very proper; but if otherwise, their being left to grow awhile (so as not to get too rude and crowding) is rather an advantage, in detaining the sap from pushing the shoots out immoderately long; and when these are taken off, the lower eye of each may be left with the same view. But the side shoot that proceeds from the top of each shortened branch, should be left on, and when it gets long, then shortened down to an eye or two.

In order to fruitfulness, vines will need dressing with some sort of manure; for though they grow in vineyard countries on rocky hills, and in very shallow soils, and have done so on some chalky, hot, gravelly hills in England, yet some warm manure they must generally have applied, or they will produce little good fruit.

Some people are very fond of exposing the fruit of the vine to the full sun, by stripping off leaves; but this should not be practised till the bunches have attained their proper size, needing only to be ripened, and even then but little should be done in this way. The loss of leaves is an injury to every plant, as it prevents the elaborating of the saccharine juices necessary to perfect the fruit.

Fig-trees are best pruned early in spring, as after an autumn cutting (if late) they are apt to die down. The mode of bearing in the fig is, that fruit chiefly comes the present year on the little shoots from wood of the preceding, and that towards the ends of the branches, which circumstances dictate the rules for pruning. Two-years-old wood will bear some, but older wood never.

The shoots, during summer, are to be laid in at full length, plentifully, as room will permit. The weak, ill-placed, or superabundant ones, cut clean out; yet rather break, or rub them off, in an early state of growth, for cutting branches or shoots in summer is apt to make them bleed as it is called, *i. e.* the sap run; when cut in autumn, the fig will sometimes bleed for a day, but if late-cut in spring, the oozing will continue perhaps a week.

At the principal pruning, the strongest and the closest-jointed shoots are to be preferred, and left about seven or eight inches asunder, without shortening. Let the spare shoots be cut out close and smooth, and as much of the old wood as may be; for the tree will increase too fast, and get too naked of bearing wood in the middle, if this is not freely done; and the essential point in the management of the fig-tree is (as indeed of all wall-trees) to have young wood all over it, and particularly in the middle, and towards the bottom. Wood is seldom wanted in a fig-tree; but where it is, the shortening of a shoot, properly situated (by taking off the leading bud, or cutting lower, as the case requires), is sure to produce it. Do this in April, as the best time.

When hard frosts are expected, strew some ashes and some litter over the roots of fig-trees. Mats should be nailed over their branches (first pulling off the figs), as the succulent nature of their wood makes them tender. These coverings are to remain till the frosts are judged to be over, and then let them be covered up at night, and not by day, for a week or two, to harden them by degrees.

But fig-trees will mostly survive hard winters when in standards, without covering; and though shoots trained to a wall are tenderer, yet peas-haulm hung close among the branches (at the approach of sharp frosts) will preserve them. This sort of protection, as affording plenty of air, is by many good gardeners preferred to the more common practice of matting. But if mats were contrived to roll up and down, or kept a little distance from the tree, so as to give more or less air as the weather is, the health and fruitfulness of the tree would be better ensured, for too close (and, as it commonly happens in consequence, too long) covering is injurious to both. Fig-trees that have been close covered are often hurt by an early uncovering, and yet the spring air, as soon as possible, is desirable.

Pears being planted against a wall in autumn, should not be cut down till spring, when the head is to be reduced according to the goodness of the root, and so as to lay a proper foundation for covering the wall.

The mode of bearing in pear-trees is on short spurs, which appear first towards the ends, and then form themselves all along the branches, which do not produce blossoms for three or four years from planting, and sometimes (according to the sort, or perhaps soil) for several years more. When they are come to fruiting, some pears bear pretty much on year-old wood, some on two, others on three. The same branches continue to bear on spurs from year to year, and most when five or six years old; but as in course of time the branches may become diseased and barren, and not produce so fine fruit as younger wood, it is always proper to procure a succession of young bearers, as the opportunity of good shoots offer, cutting out old wood.

The time for general or winter pruning of pear-trees ought to be November, as the blossoms are then very discernible, and at spring pruning they get so turgid and tender, that almost the least touch knocks them off, or even the jarring of the tree.

Apples are sometimes planted against walls, and what has been said of pruning and managing pears is applicable to them; the branches, however, may be laid in somewhat closer, as they will not require so much room; yet they ought to have from twenty-five feet in length of a low wall, or on a high one something less.

Mulberries require good room, as their mode of bearing is mostly at the end of the trained shoots, which are therefore not to be shortened. Twenty or twenty-five feet should be allowed them, and a new-planted tree is to be headed down as directed for pears, &c. A succession of new wood must be always coming forward, and of course some old taken out, for the fruit is produced chiefly on year and two-year old wood; and as it comes on spurs, and also small shoots of the same year, the leaving short stubs (of moderate wood) in pruning, seems justified, though by some condemned.

Cherry-trees, if against a wall, should be trained at length, four or five inches asunder. The fruit comes from spurs all along the shoots, on one and two years old wood, which will continue to bear. In pruning, have an eye, however, to some fair shoots for successors to those that are getting diseased, or worn out. Some cut all superfluous shoots clean away, and others leave a sprinkling of short stubs, which may be allowed; but let them not advance far foreright.

Plums of the finer sorts are often planted against walls, and deserve a good one. For the pruning of plum-trees, the directions given for cherries apply to them, only that the branches should be laid somewhat wider, *i. e.* at five or six inches, according to the sort, as free or less free in their growth.

Currants and gooseberries bear fruit upon young wood, and on little spurs of the old. Superfluous shoots are to be cut down to little stubs or spurs, about half an inch long, which will throw out fruit-shoots and spurs. The mother-branches of currants and gooseberries will last many years; but when good young wood can be brought in for principals, a renewal every three or four years is necessary to produce fine fruit.

The work of pruning espalier-trees is much the same as for wall-trees.

As trees planted for espalier training should be young, let great care be taken to set them off right at first, by regular shoots, full furnished immediately from the stem, which is effected by proper heading down. Apples, pears, plums, cherries, &c. in general, need not to be so much freed of all branches at planting, as peaches, nectarines, and apricots. There are, however, gardeners who prune down to the stem all sorts of wall and espalier trees, as peaches are.

The principle of pruning standard trees is the same, whether full, half, or dwarf standards; and the object is, to form a compact handsome round and open head, rather small than large, equal on all sides, with tolerably erect wood, capable (as far as the art of the pruner can go) of supporting the fruit without much bending. Perfect symmetry indeed is not necessary: but confusion of branches, weak and crossing, crowded and dangling, is to be prevented by pruning; for a proper use of the knife is capable of doing much towards the beauty and fruitfulness of standard trees. A little pruning of standards every year, and a general one every three or four years, to cut out what is decayed, and some of the older wood where a successional supply of young may be obtained to succeed, is the way to keep them in vigour, and have the best of fruit; for that which grows on old wood gets small and austere. To take off large branches, a thin broad chisel is proper; but if a saw is used, smooth the part with a knife.

Clear trees from moss, by scraping them with a long narrow-bladed blunt knife, on a bit of hard wood; and cut or rub off bits of decayed bark, in which insects are apt to breed, and wipe the part clean. Some use a scouring-brush, the long end-hairs of which are well adapted to clean the forky parts. A bit of hair cloth is also used for the purpose; and a finish is properly made to do the business well, with a brush and soap and water.

Of pruning shrubs. Many shrubs are cultivated for their ornament, and some for their fruit; of the latter kind are raspberries and barberries.

Raspberries bear fruit on little side shoots of the present year, proceeding from stems of the last, and sometimes produce a little on those of the same year. To prune or dress the shrub, therefore, first cut out all the old bearers, whose wood dies; then cut out, close to the stool, all the new shoots, except three or four of the strongest, which may be carefully twisted from the bottom upwards, or tied together at the top, or if upright and strong, left to support themselves singly.

The barberry is a beautiful and somewhat large shrub, which should be suffered to grow with a full head, like a dwarf standard tree. It bears along the sides of both young and old wood, but chiefly towards the ends, and its branches should therefore not be shortened, except with a view to throw out wood. Keep the root free from suckers, and the stem from shoots in its lower part, and prune out weak, luxuriant, straggling, and crossing branches, forming it to a somewhat round head, which keep moderately open. Let the stem be freed from lower branches to the height of three, four, or five feet, according as the shrub may be desired to approach to a tree.

Flowering shrubs are of great variety, and the method of pruning them is to be determined according to the several modes of bearing, of which consider chiefly these; that is, whether they produce their flowers upon the last year's shoots or the present, on the ends or the sides of their branches. If a shrub bears on the last year's shoots, it is evident that it must be cut away no more than is necessary to keep it within bounds, open and handsome as to its form; in this case it is the business to cut clean out, or very low, what is to be spared. If a shrub bears on the present year's shoots, the old wood may and must be cut down freely, so however as to leave eyes enough for new shoots to proceed from, to make a sufficient head and show. If the shrub bears altogether or chiefly at its ends, no shortening must take place; but if some of the branches are too long, they may be either cut out, or quite low, leaving the shorter ones to bear. If the shrub bears along its sides, the shortening is of no consequence, and the desired form may be freely provided for at pleasure.

The season for pruning shrubs is generally the spring; but autumn is better, if not too near winter, as at this time sharp weather might occasion some of the sorts (as jasmines and honeysuckles) to die down. The time of flowering must in some measure direct the time of pruning. Shrubs that flower in winter (as the laurustinus) should be cut in spring. Those that flower in spring may be pruned immediately after their blow, or in summer. Those that flower in summer should be pruned in autumn; and those that flower in autumn should be pruned either soon after flowering, or in spring.

Be sure to take off in time, *i. e.* as soon as discovered, all suckers and over-strong shoots from shrubs; for by their luxuriancy they greatly impoverish the proper-sized branches, which are the fruitful ones, and such large sappy wood looks very unsightly.

The height of shrubs in certain situations is material, and to provide for this, the art of pruning is in a great measure competent. To keep them low, cutting down is of course necessary; but it will be well also to make the soil poor if too rich. To encourage them to mount, keep trimming off close the lower branches, and improve the ground by digging and dressing occasionally.

Roses bear upon shoots of the present year, and upon those formed after midsummer in the past year, but chiefly upon the former. Therefore they may, or rather should, be cut down low, leaving only three or four eyes to a shoot; except some of those short shoots formed the last year too late to blow then, leave whole. If rose-trees are not close pruned, they will be unable to support their flowers properly. Use a sharp knife, and cut close behind an eye or bud. Roses for forcing should be pruned in July and August.

Honeysuckles flower on shoots of the present year, and therefore whether trained to walls, or kept in bushes, should be also pruned close; but not so short in the latter case as the former, for those against walls should be cut down to an eye or two, and those in bushes to three or four eyes.

Sweetbriars flower on shoots of the present year, and therefore should be cut after the manner of honeysuckles. These shrubs (and most others) are seldom pruned down enough, so that in a few years they get very rambling and unsightly; but if kept compact, we have beauty as well as sweetness, to recompense our care. In all cases, a less number of fine flowers obtained by short and open pruning, is certainly preferable to many indifferent ones.

Lilacs bear their flowers at the ends of shoots of the last year, so of course at spring must not be shortened. If rambling and crowded, cut either clean out, or very low, what may be superfluous. If they need much reduction, let them be cut down as soon as (or somewhat before) they have got off flower.

To enter further into the detail of shrubs would be inconsistent with our limits. The reader will find some directions occasionally under the separate articles, and will commonly act safely under the general directions above.

PRUNUS, a genus of the monogynia order, in the icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. The calyx is quinquefid, inferior; there are five petals; the fruit is a plum, having a kernel with prominent sutures. There are thirty-three species, of which six are cultivated in Britain: they are originally natives of America and Siberia.

1. The domestica, or common plum-tree, grows 20 or 30 feet high, with oval spear-shaped leaves, and with the pedunculi for the most part single, terminated by flowers, succeeded by plums of many different colours, sizes, and shapes, in the varieties. 2. The insititia, wild-plum, or bullace-tree grows 12 or 15 feet high; the branches somewhat spinous; the leaves oval, hairy underneath; and the pedunculi by pairs, terminated by white flowers succeeded by small, round, plum-like fruit, of different colours in the varieties. 3. The spinosa, black-thorn, or sloe-tree, grows 10 or 12 feet high, very branchy and bushy quite from the bottom, armed with strong, sharp spines, small, spear-shaped, smooth leaves, pedunculi growing singly, terminated by flowers, succeeded by small, round, black cherries in autumn. It grows wild every where in hedges and woods; and is very proper for planting field-hedges, being of very quick and close growth. 4. The cerasus, or common cherry-tree, grows 20 feet or more in height, with oval clusters of lanceolate smooth leaves, umbellate flowers, succeeded by clusters of red roundish fruit, of different sizes and properties in the varieties. Hanbury says, "were this tree scarce, and with much difficulty propagated, every man, though possessed of a single tree only, would look upon it as a treasure; for besides the charming appearance these trees have when besnowed, as it were, all over with bloom in the spring, can any tree in the vegetable tribe be conceived more beautiful, striking, and grand, than a well-grown and healthy cherry-tree, at that period when the fruit is ripe?"

The cherry-trees afford an almost endless variety; all differing in some respect in their manner of shooting, leaves, flowers, and fruit: two in particular demand admission into the pleasure-garden, the double-blossomed and the red-flowering. The pleasing show the common cherry-tree makes when in blow is known to all; but that of the double-blossomed is much more enchanting. It blossoms like the other in May; the flowers are produced in large and noble clusters; for each separate flower is as double as a rose, is very large, and placed on long and slender footstalks, so as to occasion the branches to have an air of ease and freedom. They are of a pure white; and the trees will be so profusely covered with them, as to charm the imagination. Standards of these trees, when viewed at a distance, have been compared to balls of snow; and the nearer we approach, the greater pleasure we receive. These trees may be kept as dwarfs, or trained up to standards; so that there is no garden or plantation to which they will not be suitable. By the multiplicity of the petals, the organs of generation are destroyed: so that those flowers which are really full are never succeeded by any fruit.

The red-flowering cherry-tree differs in no respect from the common cherry-tree, only that the flowers are of a pale-red colour, and by many are esteemed on that account. Besides the ornament and utility afforded us by the flowers and fruit of the cherry, its timber is a further inducement for propagating it; more especially that of the small black wilding sort, which may perhaps with propriety be considered as the genuine species, and a native of this island. Be this as it may, it will grow in a soil and situation it affects, to be a large timber-tree; and if taken in its prime before it becomes tainted at the heart, will turn out perhaps not less than a ton of valuable materials, peculiarly adapted to the purposes of furniture. The grain is fine, and the colour nearly approaching to that of mahogany, to which valuable wood it comes nearer than any other which this country produces. 5. The avium, or great wilding cherry-tree, grows 40 or 50 feet high, having oval or spear-shaped leaves, downy underneath, with umbellate sessile clusters of white flowers, succeeded by small round fruit of different properties in the varieties. 6. The padus, or common bird cherry-tree, grows 15 or 20 feet high, of a shrub-like growth, with a spreading head, large, oblong, rough, serrated leaves, having two glands at the back of the base like the other, and with shorter, more compact, clusters of flowers, succeeded by large red fruit. This grows wild in hedges in the north part of England. 7. The Virginiana, or Virginian bird-cherry, grows 30 feet high, dividing into a very branchy head, having a dark-purple bark, oval, slightly serrated, shining green leaves, having two glands at the fore part of the base, and long clusters of white flowers, succeeded by small, round, berry-like, black fruit. 8. Canadensis, or Canada dwarf bird-cherry, grows but four or five feet high, branching horizontally near the ground with smooth branches; broad, spear-shaped, rough, downy leaves without glands; and long clusters of white flowers, succeeded by small, round, berry-like black fruit, ripe in autumn. 9. The mahaleb, or perfumed cherry, grows 10 or 15 feet high, with smooth whitish branches, small, oval, shining, green leaves, and corymbous clusters of white flowers, succeeded by small fruit. 10. The armeniaca, or apricot-tree, grows 20 feet high, with a large spreading head, having reddish shoots, large, nearly heart-shaped leaves, close-sitting pale-red flowers rising all along the sides of the young branches, succeeded by large roundish fruit of a yellow and reddish colour in different varieties. The fruit and the kernels of the prunus Siberica, when eaten, excite a continued head-ache: the kernels, infused in brandy, communicate an agreeable flavour.

All the different varieties of plums have at first been raised from the stones, and are afterwards preserved by budding and grafting on any plum-stock. The same method is applicable to cherries; only these are grafted to most advantage upon stocks of the wild black and red cherry raised from the stones of the fruit. The apricot-trees are propagated by budding on any kind of plum-stocks.

PRUSSIATS, salts formed with prussic acid. Of these the most important are,

1. *Prussiat of lime*, formed by dissolving lime in prussic acid, filtring the solution, and separating the uncombined lime. It is decomposed by all the other acids, and by alkalies.

2. *Prussiat of magnesia.* This salt may be formed by putting pure magnesia into prussic acid. In a few days the earth is dissolved, and the compound formed. The magnesia is precipitated by the alkalies and lime, and by exposure to the air.

3. *Prussiats of iron.* As the prussiats of iron enter as ingredients into the triple salts formed by the prussic acid, it will be necessary to give some account of them before entering upon the consideration of these triple salts.

It has been demonstrated by chemists, that there are no fewer than four prussiats of iron; namely,

1. White prussiat,
2. Blue prussiat,
3. Yellow prussiat,
4. Green prussiat.

The white prussiat discovered by Mr. Proust is composed of prussic acid and protoxide of iron. It becomes gradually blue when exposed to the atmosphere, because the oxide absorbs oxygen, and is converted into peroxide.

Blue prussiat, or Prussian blue, is composed of prussic acid and peroxide of iron. It is a deep-blue powder, insoluble in water, and scarcely soluble in acids. It is composed, according to the most accurate experiments hitherto made, of equal parts of oxide of iron and prussic acid. It is not affected by exposure to the air. Heat decomposes it by destroying the acid, and the oxide of iron remains behind. The Prussian blue of commerce, besides other impurities, contains mixed with it a great quantity of alumina.

Yellow prussiat is composed of prussic acid combined with an excess of peroxide of iron: it is therefore a sub-prussiat of iron. This prussiat is soluble in acids. It may be obtained by digesting the alkalies or alkaline earths with Prussian blue. Part of the acid is carried off by these bodies, and the yellow prussiat remains in the state of a powder.

Green prussiat, first discovered by Mr. Berthollet, is composed of oxyprussic acid, and peroxide of iron. It is therefore in fact an oxyprussiat.

4. *Prussiat of barytes and iron.* For the first accurate description of this salt, we are indebted to the ingenious Mr. William Henry. It may be formed by adding Prussian blue to hot barytes water till it ceases to be discoloured. The solution, when filtred and gently evaporated, yields crystals of prussiat of barytes and iron.

These crystals have the figure of rhomboidal prisms: they have a yellow colour, and are soluble in 1920 parts of cold water, and in about 100 parts of boiling water. In a red heat they are decomposed, the acid being destroyed. They are soluble in nitric and muriatic acids: sulphuric acid occasions a precipitate of sulphat of barytes.

5. *Prussiat of lime and iron.* This salt was perhaps first mentioned by Mr. Hagen; but we are indebted to Morveau for the first accurate account of its properties and preparation.

Upon two parts of Prussian blue of commerce, previously well washed with a sufficient quantity of boiling water to separate all the foreign salts, about 56 parts of lime-water are to be poured, and the mixture must be boiled for a short time till the lime is saturated with the prussic acid, which is known by its no longer altering paper stained with turmeric: it is then to be filtred.

This liquid, which contains the triple prussiat of lime in solution, has a greenish-yellow colour: its specific gravity is 1.005; and it has an unpleasant bitterish taste. When evaporated to dryness, it yields small crystalline grains, soluble without alteration in water. It is insoluble in alcohol.

This triple prussiat may be used with advantage as a test to ascertain the presence of metals held in solution. The only impurity which it contains is a little sulphat of lime.

6. *Prussiat of potass and iron.* This salt, known also by the names of Prussian alkali, phlogisticated alkali, Prussian test, triple prussiat of potass, &c. has been chosen by chemists as the best combination of prussic acid for detecting the presence of metals, and more especially for detecting the existence of iron. To chemists and mineralogists, it is one of the most important instruments ever invented; as, when properly prepared, it is capable of indicating whether any metallic substance (platinum excepted) is present in any solution whatever, and even of pointing out the particular metal, and of ascertaining its quantity. This it does by precipitating the metals from their solution in consequence of the insoluble compound which it forms with them; and the colour of the precipitate indicates the particular metal, while its quantity enables us to judge of the proportion of metallic oxide contained in any solution.

In order to be certain of the accuracy of these results, it is necessary to have a Prussian alkali perfectly pure, and to be certain beforehand of the quantity, or rather of the proportions, of its ingredients. To obtain a test of this kind has been the object of chemists ever since the discoveries of Macquer pointed out its importance. It is to the use of impure tests that a great part of the contradictory results of mineralogical analysis by different chemists is to be ascribed.

The great object of chemists at first was to obtain this prussiat entirely free from iron; but their attempts uniformly failed, because the oxide of iron is one of its necessary component parts. This was first properly pointed out by Morveau.

There are two ways in which this test may be rendered impure, besides the introduction of foreign ingredients, which it is needless to mention, because it is obvious that it must be guarded against. 1. There may be a superabundance of alkali present, or, which is the same thing, there may be mixed with the Prussian test a quantity of pure alkali: or, 2. There may be contained in it a quantity of yellow prussiat of iron, for which prussiat of potass has also a considerable affinity.

If the Prussian test contains a superabundance of alkali, two inconveniences follow. This superabundant quantity will precipitate those earthy salts which are liable to contain an excess of acid, and which are only soluble by that excess: hence alumina and barytes will be precipitated. It is to the use of impure tests of this kind that we owe the opinion, that barytes and alumina are precipitated by the Prussian alkali, and the consequent theories of the metallic nature of these earths. This mistake was first corrected by Meyer of Steint.

Another inconvenience arising from the superabundance of alkali in the Prussian test is, that it gradually decomposes the blue prussiat which the test contains, and converts it into yellow prussiat. In what manner it does this will be understood, after what has been said, without any explanation.

On the other hand, when the Prussian alkali contains a quantity of yellow prussiat of iron, as great inconveniences follow. This yellow prussiat has an affinity for prussic acid, which, though inferior to that of the potass, is still considerable; and, on the other hand, the potass has a stronger affinity for every other acid than for the prussic. When, therefore, the test is exposed to the air, the carbonic acid which the atmosphere always contains, assisted by the affinity between the yellow prussiat and the prussic acid, decomposes the prussiat of potass in the test, and the yellow prussiat is precipitated in the form of Prussian blue; and every other acid produces the same effect. A test of this kind would indicate the presence of iron in every mixture which contains an acid (for a precipitation of Prussian blue would appear), and could not therefore be employed with any confidence.

To describe the various methods proposed by chemists for preparing this salt would be unnecessary, as the greater number do not answer the purpose intended. The method practised by Klaproth, first made known to chemists by Westrum, and afterwards described in our language by Kirwan, is considered as one of the best. It is as follows:

Prepare pure potass, by gradually projecting into a large crucible, heated to whiteness, a mixture of equal parts of purified nitre and crystals of tartar; when the whole is injected, let it be kept at a white heat for half an hour, to burn off the coal. Detach the alkali thus obtained from the crucible, reduce it to powder, spread it on a muffle, and expose it to a white heat for half an hour. Dissolve it in six times its weight of water, and filtre the solution while warm. Pour this solution into a glass receiver, placed in a sand-furnace heated to 170° or 180°; and then gradually add the best Prussian blue in powder, injecting new portions according as the former become grey, and supplying water as fast as it evaporates; continue until the added portions are no longer discoloured, then increase the heat to 212°, and continue it for half an hour. Filtre the ley thus obtained, and saturate it with sulphuric acid moderately diluted; a precipitate will appear: when this ceases, filtre off the whole, and wash the precipitate. Evaporate the filtred liquor to about one quarter, and set it by to crystallize: after a few days, yellowish crystals of a cubic or quadrangular form will be found, mixed with some sulphat of potass and oxide of iron; pick out the yellowish crystals, lay them on blotting-paper, and re-dissolve them in four times their weight of cold water, to exclude the sulphat of potass.

Assay a few drops of this solution with barytes water, to see whether it contains any sulphuric acid, and add some barytes water to the remainder if necessary: filtre off the solution from the sulphat of barytes, which will have precipitated, and set it by to crystallize for a few days; that the barytes, if any should remain, may be precipitated. If the crystals now obtained are of a pale yellow colour, and discover no blueish streaks when sprinkled over with muriatic acid, they are fit for use; but if they still discover blueish or green streaks, the solutions and crystallizations must be repeated.

These crystals must be kept in a well-stopped bottle, which, to preserve them from the air, should be filled with alcohol, as they are insoluble in it.

Before they are used, the quantity of iron they contain should be ascertained, by heating 100 grains to redness for half an hour in an open crucible: the prussic acid will be consumed, and the iron will remain in the state of a reddish-brown magnetic oxide, which should be weighed and noted. This oxide is half the weight of the Prussian blue afforded by the Prussian alkali: its weight must therefore be subtracted from that of metallic precipitates formed by this test. Hence the weight of the crystals, in a given quantity of the solution, should be noted, that the quantity employed in precipitation may be known. Care must be taken to continue the calcination till the oxide of iron becomes brown; for while it is black, it weighs considerably more than it should.

Another good method of preparing this salt has been lately given by Mr. Henry; but it is rather too expensive for general use. It consists in first forming a triple prussiat of barytes, and adding it in crystals to a solution of carbonat of potass till the solution no longer restores the colour of reddened litmus paper. After digesting the mixture for half an hour, filtre the liquid, and evaporate it gently. The triple prussiat of potass crystallizes.

PRUSSIC ACID, is one of the most important instruments which the chemist possesses. It was discovered about a century ago by Diésbach at Berlin; and a method of preparing it was published by Woodward in the Philosophical Transactions for 1724, which he said he had got from one of his friends in Germany. This method was as follows: Detonate together four ounces of nitre and as much tartar, in order to procure an extemporaneous alkali; then add four ounces of dried bullock's blood; mix the ingredients well together, and put them into a crucible covered with a lid, in which there is a small hole; calcine with a moderate fire till the blood emits no more smoke or flame capable of blackening any white body exposed to it: increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately but sensibly red. In this state throw it into two pints of water, and boil it for half an hour. Decant off this water, and continue to pour on more till it comes off insipid. Add all these liquids together, and boil them down to two pints. Dissolve two ounces of sulphat of iron and eight ounces of alum in two pints of boiling water; mix this with the former liquor while both are hot. An effervescence takes place, and a powder is precipitated, of a green colour mixed with blue. Separate this precipitate by filtration, and pour muriatic acid upon it till it becomes of a beautiful blue; then wash it with water and dry it.

Different explanations were given of the nature of this precipitate by different chemists. All of them acknowledged that it contained iron; but to account for the colour was the difficult point. Brown, and Geoffroy, and Neuman, discovered in succession, that a great many other animal substances besides blood communicated to alkalies the property of forming Prussian blue; but the theories by which they attempted to account for its formation were altogether nugatory. At last a very important step was made in the investigation of this compound by Macquer, who published a dissertation on it in the year 1752.

This celebrated chemist ascertained the following facts: 1. When an alkali is added to a solution of iron in any acid, the iron is precipitated of a yellow colour, and soluble in acids; but if iron is precipitated from an acid by an alkali prepared by calcination with blood (which has been called a Prussian alkali), it is of a green colour. 2. Acids dissolve only a part of this precipitate, and leave behind an insoluble powder, which is of an intense blue colour. The green precipitate, therefore, is composed of two different substances, one of which is Prussian blue. 3. The other is the brown or yellow oxide of iron; and the green colour is owing to the mixture of the blue and yellow substances. 4. When heat is applied to this Prussian blue, its blue colour is destroyed, and it becomes exactly similar to common oxide of iron. It is composed, therefore, of iron and some other substance, which heat has the property of driving off. 5. If it is boiled with a pure alkali, it loses its blue colour also, and at the same time the alkali acquires the property of precipitating of a blue colour solutions of iron in acids, or it has become precisely the same with the Prussian alkali. 6. Prussian blue, therefore, is composed of iron and something which a pure alkali can separate from it, something which has a greater affinity for alkali than for iron. 7. By boiling a quantity of alkali with Prussian blue, it may be completely saturated with this something, which may be called colouring matter. 8. No acid can separate this colouring matter from iron after it is once united with it. 9. When iron dissolved in an acid is mixed with an alkali saturated with the colouring matter, a double decomposition takes place, the acid unites with the alkali, and the colouring matter with the iron, and forms Prussian blue. 10. The reason that, in the common method of preparing Prussian blue, a quantity of yellow oxide is precipitated, is, that there is not a sufficient quantity of colouring matter (for the alkali is never saturated with it) to saturate all the iron displaced by the alkali; a part of it, therefore, is mixed with Prussian blue. Muriatic acid dissolves this oxide, carries it off, and leaves the blue in a state of purity.

Such were the conclusions which Macquer drew from his experiments; experiments which not only discovered the composition of Prussian blue, but threw a ray of light on the nature of affinities, which has contributed much towards the advancement of that important branch of chemistry.

The nature of the colouring matter, however, was still unknown. At length, in 1772, Morveau announced his suspicion that the colouring matter was probably an acid.

Such was the knowledge of chemists respecting the nature of this colouring matter, when Scheele all at once removed the veil, and explained its properties and composition. He observed that the Prussian alkali, after being exposed for some time to the air, lost the property of forming Prussian blue; the colouring matter must therefore have left it. He put a small quantity of it into a large glass globe, corked it up, and kept it some time; but no change was produced either in the air or the Prussian alkali. Something must therefore displace the colouring matter when the alkali is exposed to the open air, which is not present in a glass vessel. Was it carbonic acid gas? To ascertain this, he put a quantity of Prussian alkali into a glass globe filled with that gas, and in 24 hours the alkali was incapable of producing Prussian blue. It is therefore carbonic acid gas which displaces the colouring matter. He repeated this experiment with this difference, that he hung in the globe a bit of paper which had been previously dipped into a solution of sulphat of iron, and on which he had let fall two drops of an alkaline lixivium in order to precipitate the iron. This paper was taken out in two hours, and became covered with a fine blue on adding a little muriatic acid. Carbonic acid, then, has the property of separating the colouring matter from alkali without decomposing it.

He found also that other acids produce the same effect. Hence he concluded, that the colouring matter might be obtained in a separate state. Accordingly he made a great many attempts to procure it in that state, and at last discovered the following method, which succeeds perfectly:

Mix together ten parts of Prussian blue in powder, five parts of the red oxide of mercury, and thirty parts of water, and boil the mixture for some minutes in a glass vessel. The blue colour disappears, and the mixture becomes yellowish-green. Pour it upon a filtre; and after all the liquid part has passed, pour ten parts of hot water through the filtre to wash the residuum completely. The oxide of mercury decomposes Prussian blue, separates its colouring matter, and forms with it a salt soluble in water. The liquid, therefore, which has passed through the filtre contains the colouring matter combined with mercury. The other component parts of the Prussian blue, being insoluble, do not pass through the filtre. Pour this mercurial liquid upon 2½ parts of clean iron filings, quite free from rust. Add at the same time one part of concentrated sulphuric acid, and shake the mixture. The iron filings are dissolved, and the mercury formerly held in solution is precipitated in the metallic state. The cause of this sudden change is obvious: the iron deoxidizes the mercury, and is at the same instant dissolved by the sulphuric acid, which has a stronger affinity for it than the colouring matter has. There remain in solution, therefore, only sulphat of iron and the colouring matter.

Now the colouring matter being volatile, which the sulphat of iron is not, it was easy to obtain it apart by distillation. Accordingly he distilled the mixture in a gentle heat: the colouring matter came over by the time that one-fourth of the liquor had passed into the receiver. It was mixed, however, with a small quantity of sulphuric acid; from which he separated it by distilling a second time over a quantity of carbonat of lime. The sulphuric acid combines with the lime, and remains behind, which the colouring matter cannot do, because carbonic acid has a stronger affinity for lime than it has. Thus he obtained the colouring matter in a state of purity.

It remained now to discover its component parts. He formed a very pure Prussian blue, which he distilled, and increased the fire till the vessel became red. The small quantity of water which he had put into the receiver contained a portion of the blue colouring matter and of ammonia; and the air of the receiver consisted of azote, carbonic acid gas, and the colouring matter. He concluded, from this and other experiments, that the colouring matter is a compound of ammonia and oil. But when he attempted to verify this theory by combining together ammonia and oil, he could not succeed in forming colouring matter. This obliged him to change his opinion; and at last he concluded that the colouring matter is a compound of ammonia and charcoal. He mixed together equal quantities of pounded charcoal and potass, put the mixture into a crucible, and kept it red-hot for a quarter of an hour: he then added a quantity of sal ammoniac in small pieces, which he pushed to the bottom of the melted mixture, kept it in the fire for two minutes till it had ceased to give out vapours of ammonia, and then threw it into a quantity of water. The solution possessed all the properties of the Prussian alkali. Thus Mr. Scheele succeeded in forming the colouring matter.

This colouring matter was called prussic acid by Morveau, in the first volume of the chemical part of the Encyclopedie Methodique; an appellation which is now generally received.

These admirable experiments of Scheele were repeated and carried still farther, by Berthollet in 1787, who applied to the explanation of the composition of the colouring matter the light which had resulted from his previous experiments on the component parts of ammonia. This illustrious chemist, scarcely inferior to Scheele in ingenuity and address, ascertained, in the first place, that the prussic alkali is a triple salt, composed of prussic acid, the alkali, and oxide of iron; that it may be obtained in octahedral crystals; and that when mixed with sulphuric acid, and exposed to the light, it lets fall a precipitate of Prussian blue. His next object was, to ascertain the component parts of prussic acid. When oxymuriatic acid is poured into prussic acid obtained by Scheele's process, it loses its oxygen, and is converted into common muriatic acid. At the same time the prussic acid becomes more odorous and more volatile, less capable of combining with alkalies, and precipitates iron from its solutions, not blue, but green. Thus prussic acid, by combining with oxygen, acquires new properties, and is converted into a new substance, which may be called oxyprussic acid. If more oxymuriatic acid gas is made to pass into prussic acid, and it is exposed to the light, the prussic acid separates from the water with which it was combined, and precipitates to the bottom in the form of an aromatic oil; which heat converts into a vapour insoluble in water, and incapable of combining with iron. When the green precipitate, composed of oxyprussic acid and iron, is mixed with a pure fixed alkali, the oxyprussic acid is decomposed, and converted into carbonat of ammonia.

From these experiments, Berthollet concluded, that prussic acid does not contain ammonia ready-formed; but that it is a triple compound of carbon, hydrogen, and azote, in proportions which he was not able to ascertain. This conclusion has been still farther verified by Mr. Clouet, who found that when ammoniacal gas is made to pass through a red-hot porcelain tube containing charcoal, a quantity of prussic acid is formed. This experiment does not succeed unless a pretty strong heat is applied to the tube.

Fourcroy and several other chemists believe, that the prussic acid contains also a portion of oxygen in its composition, resting chiefly upon the following experiments of Vauquelin:

Exper. I. Put into a retort 100 parts of the muriat of ammonia, 50 parts of lime, and 25 parts of charcoal in fine powder; adapt to the retort a receiver containing a slight solution of the sulphat of iron, and immerse into it the beak of the retort; then apply a brisk heat, and continue the action of the fire until nothing more is disengaged.

Exper. II. Put into a retort 100 parts of the muriat of ammonia, 50 parts of semivitreous oxide of lead, and 25 parts of charcoal: adapt a receiver containing a solution of sulphat of iron, and proceed as before. Stir well the liquors contained in the receivers, and expose them to the air for several days, in order that the combination between the oxide of iron and the prussic acid may be perfect, and that the prussiat of iron may absorb as much oxygen as is necessary for its passing to the state of blue prussiat, and for its being proof against acids: then pour into these liquors equal quantities of sulphuric acid well diluted with water, and you will have Prussian blue, the quantities of which will be as one to six; that is to say, the Prussian blue of the experiment in which Vauquelin employed oxide of lead, was six times more abundant than that of the experiment in which he employed only lime to disengage the ammonia.

Having thus traced the gradual progress of philosophers in ascertaining the nature of the prussic acid, it only remains to give an account of its properties, which were first examined by the indefatigable Scheele.

Prussic acid obtained by Scheele's process is a colourless liquid like water. It has a strong odour, resembling that of the flowers of the peach, or of bitter almonds. Its taste is sweetish, acrid, and hot, and apt to excite cough. It does not alter the colour of vegetable blues.

It is exceedingly volatile, and evidently capable of assuming the gaseous form; though it has never been obtained apart, nor examined in that state. At a high temperature (when united to a base), it is decomposed and converted into ammonia, carbonic acid, and carbureted hydrogen gas.

It unites difficultly with alkalies and earths, and is separated from them much more easily than from metallic oxides. More exposure to the light of the sun, or to a heat of 110°, is sufficient for that purpose. These combinations are decomposed also by all the acids.

It has no action on metals; but it unites with their oxides, and forms with them salts, which are almost all insoluble, if we except prussiats of mercury and manganese. These compounds are not decomposed by acids. Yet the prussic acid is not capable of taking the metallic oxides from the other acids.

Prussic acid has a great tendency to enter into triple compounds, combining at once with an alkali and a metallic oxide; and these compounds are much more permanent and difficult to decompose than its single combinations.

The affinities of this acid, as far as they have been ascertained, are as follows:

Barytes,
Strontian,
Potass,
Soda,
Lime,
Magnesia,
Ammonia.

It does not seem capable of combining with alumina.

This acid is of great importance to the chemist, in consequence of the property which it has of forming insoluble compounds with metallic oxides, and almost with metallic oxides alone. This puts it in our power to ascertain the presence of a metallic body held in solution. When the prussic acid is dropt in, a precipitate appears if a metal is present. The colour of this precipitate indicates the metal, and the quantity of it enables us to ascertain the quantity of metal contained in the solution. It is used especially to indicate the presence of iron, which it does by the blue colour that the solution assumes; and to free solutions from iron, which it does by precipitating the iron in the form of Prussian blue.

It is evident, however, that the pure prussic acid cannot be employed for these purposes, because it is incapable of taking metallic oxides from other acids. It is always employed combined with an alkaline or earthy basis. In that state it decomposes all metallic salts by a compound affinity. The base most commonly employed is potass or lime; and indeed it is most usually employed in the state of a triple salt, composed of prussic acid, potass, and oxide of iron, which is preferred because it is not apt to be decomposed by the action of the atmosphere.

Of all the metallic solutions tried by Scheele, pure prussic acid occasioned only a precipitate in three, namely,

1. Nitrat of silver precipitated white.
2. Nitrat of mercury . . . black.
3. Carbonat of iron . . . green becoming blue.

It has no action on the oxides of

Platinum,	Antimony,
Iron,	Manganese,
Tin,	Arsenic acid,
Lead,	Molybdic acid.
Bismuth,	

Gold precipitated by the alkaline carbonats, is rendered white by this acid.

It disengages carbonic acid from the oxide of silver precipitated by the same alkalies; but the oxide remains white.

It dissolves red oxide of mercury, and forms with it a salt which may be obtained in crystals.

Oxide of copper precipitated by carbonat of potass, effervesces in it, and acquires a slight orange-yellow colour.

Oxide of iron precipitated from the sulphat of iron by carbonat of potass, effervesces in it, and becomes blue.

Oxide of cobalt precipitated by the same alkali, gives in it some marks of effervescence, and becomes yellowish-brown.

The compounds which prussic acid makes with zirconia and yttria, seem also to be insoluble; for these earths are precipitated from their solutions by prussiat of potass; a circumstance in which they differ from all the other earths and alkalies, and which indicates a coincidence between them and the metallic oxides.

PRYTANEUM, in Grecian antiquity, a large building in Athens, where the council of the prytanes, or presidents of the senate, assembled, and where those who had rendered any signal service to the commonwealth were maintained at the public expence.

PSIDIUM, the *guava*, a genus of the monogynia order, in the icosandria class of plants, and in the natural method ranking under the 19th order, hesperideæ. The calyx is quinquefid, superior: there are five petals: the berry is unilocular and monospermous. There are eight species. The most remarkable are:

1. The pyriferum, or white guava. 2. The pomiferum, or red guava. Both these are however thought by some to be only varieties of the same plant. The red guava rises to the height of 20 feet, and is covered with a smooth bark; the branches are angular, covered with oval leaves, having a strong midrib, and many veins running towards the sides, of a light-green colour, standing opposite upon very short footstalks. From the wings of the leaves the flowers come out upon footstalks an inch and a half long: they are composed of five large roundish concave petals, within which are a great number of stamina shorter than the petals, and tipped with pale-yellow tops. After the flower is past, the germen becomes a large oval fruit shaped like a pomegranate.

A decoction of the roots of guava is employed with success in dysenteries: a bath of a decoction of the leaves is said to cure the itch, and other cutaneous eruptions. Guayava, or guava, is distinguished from the colour of the pulp, into the two species abovementioned, the white and the red; and, from the figure of the fruit, into the round and the pear-fashioned or perfumed guava. The latter has a thicker rind, and a more delicate taste, than the other. The fruit is about the bigness of a large tennis-ball; the rind or skin generally of a russet stained with red. The pulp within the thick rind is of an agreeable flavour, and interspersed with a number of small white seeds. The rind, when stewed, is eaten with milk, and preferred to any other stewed fruit. From the same part is made marmalade; and from the whole fruit is prepared a fine jelly. The fruit is very astringent, and nearly of the same quality with the pomegranate, and should be avoided by all who are subject to costiveness. The seeds are so hard as not to be affected by the fermentation in the stomachs of animals; so that when voided with the excrements, they take root, germinate, and produce thriving trees. Whole meadows in the West Indies are covered with guavas, which have been propagated in this manner. The buds of guava, boiled with barley and liquorice, produce an excellent ptisan for diarrhœas, and even the bloody flux, when not too inveterate. The wood of the tree, employed as fuel, makes a lively, ardent, and lasting fire.

PSITTACUS, or *parrot*, a genus belonging to the order of picæ. The bill in this genus is hooked from the base; and the upper mandible is moveable: the nostrils are round, placed in the base of the bill, which in some species is furnished with a kind of cere; the tongue is broad, and blunt at one end; the head is large, and the crown flat; the legs are short, the toes placed two before and two behind. It might seem a wonder why nature has destined to this, which is not naturally a bird of prey, but feeds on fruits and vegetable substances, the crooked beak allotted to the hawk and other carnivorous birds; but the reason seems to be, that the parrot being a heavy bird, and its legs not very fit for service, it climbs up and down trees by the help of this sharp and hooked bill, with which it lays hold of any thing and secures itself before it stirs a foot; and besides this, it helps itself forward very much, by pulling its body on with this hold.

Parrots are found almost every where within the tropics; and in their natural state they live on fruits and seeds, though, when tame, they will eat flesh and even fish.

In the East and West Indies they are very common; and in such warm climates are very brisk and lively: here, however, they lose much of their vigour. They seldom make nests, but breed like owls in hollow trees: they lay two eggs. At particular times they fly in very large troops, but still they keep two and two together. The genus consists of infinite variety, not so much owing to mixture of species, however, as might be supposed. They seem to run vastly into one another, so as to appear to be related, though received from different parts of the world; this, however, may possibly be occasioned by their being carried from one place to another for the sake of sale.

Buffon ranges the parrot in two great classes; the first of which comprehends those of the Old Continent, and the second those of the New. The former he subdivides into five families; the cockatoos, the parrots properly so called, the lories, the long-tailed paroquets, and the short-tailed ones; and the latter into six, viz. the macaos, the amazonians, the creeks, the popinjays, the long-tailed paroquets, and the short-tailed ones.

Mr. Latham has increased the genus from 47 to 163; and since the time he wrote his Index, at least 20 more have been discovered. They are very generally divided into three kinds: 1. The larger, which are as big as a moderate fowl, called macaos and cockatoos; these have very long tails. 2. The middle-sized ones, commonly called parrots, which have short tails, and are a little larger than a pigeon. And, 3. The small ones, which are called paroquets, and have long tails, and are not larger than a lark or blackbird. The following are the most remarkable:

1. The psittacus macao, or red and blue macao, is red, except the wing-quills, which above are blue, before rufous; the scapular feathers are variegated with blue and green; the cheeks are naked and wrinkled. It is about two feet seven inches and a half long, and about as big as a capon. Edwards says, when perfect, it will measure a full yard from bill to tail. It inhabits Brasil, Guiana, and other parts of South America. It was formerly very common in St. Domingo, but is now rarely found there. It generally lives in moist woods, especially such as are planted with a particular kind of palm, perhaps what is called the macaw-tree. It does not in general learn to speak, and its voice is particularly rough and disagreeable. The flesh is hard, black, and unsavoury, but makes good soup, and is much used by the inhabitants of Cayenne and other places. This species, in common with other parrots, is subject to fits when tamed; and though it will live for many years, yet if the returns are pretty frequent, it will generally fall a victim to that disease at last. The Americans call it gonzalo.

2. The psittacus ararauna, or blue and yellow macaw, is blue above, and yellow below, and the cheeks are naked, with feathery lines. It is about the same size with the last, and inhabits Jamaica, Guiana, Brasil, and Surinam.

3. The psittacus severus, or Brasilian green macaw, is black, with a greenish splendour; the bill and eyes are reddish, and the legs are yellow. It is about one foot and five inches long, and is common in Jamaica, Guiana, and Brasil. It is however comparatively rare: it is extremely beautiful, and of a very amiable and sociable temper when familiar and acquainted; but it can neither bear strangers nor rivals: its voice is not strong, nor does it articulate very distinctly the word ara. See Plate Nat. Hist. figs. 338, 339.

4. The psittacus aurora, or yellow amazon, is about 12 inches long, of a green colour, with blue wing-quills, and a white front; its orbits are snowy. It inhabits Mexico or Brasil; but in all probability the latter, from the one which Salerne saw, and which pronounced Portuguese words. The psittacus guineensis, or yellow lory, is about ten inches long, and is an inhabitant of Guinea. The bill is of a black colour; the cere, the throat, and space about the eyes, are white; above the eye there is a patch of yellow, and the rest of the head and neck is crimson. The breast is yellow, wing-coverts green, and the quills are blue, edged with yellow. Under the wings, belly, thighs, vent, and to the under part of the tail, the colour is white, which last is tipped with red; the legs are dusky, and the claws black.

PSOPHIA, a genus belonging to the order gallinæ. The bill is moderate; the upper mandible is convex; the nostrils are oblong, sunk, and pervious; the tongue is cartilaginous, flat, and fringed at the end; and the legs are naked a little above the knees. The toes are three before and one behind; the last of which is small, with a round protuberance beneath it, which is at a little distance from the ground. Mr. Latham only enumerates two species:

1. Psophia crepitans, or gold-breasted trumpeter. See Plate Nat. Hist. fig. 340. Its head and breast are smooth and shining green. By the Spaniards of Maynas it is called trompetero, and by the French at Cayenne agami, under which last name Buffon describes it. It inhabits parts of South America, Brasil, Guiana, Surinam, &c. but it is most plenty in the Amazons' country. It is about 20 inches long, being about the size of a large fowl, and lays eggs rather larger, of a blue-green colour. It is met with in the Carribee islands, where it is called a pheasant, and its flesh is reckoned as good as that of a pheasant. The most characteristic and remarkable property of these birds consists in the wonderful noise they make either of themselves, or when urged by the keepers of the menagerie. Some have supposed it to proceed from the anus, and some from the belly. It is now certain, however, that this noise proceeds from the lungs. Another very remarkable circumstance is, that they follow people through the streets, and out of town, and sometimes even perfect strangers. It is difficult to get rid of them; for if you enter a house, they will wait your return, and again join you, though often after an interval of three hours. "I have sometimes (says M. de la Borde) betaken myself to my heels; but they ran faster, and always got before me; and when I stopped, they stopped also. I know one (continues he) which invariably follows all the strangers who enter his master's house, accompanies them into the garden, takes as many turns as they do, and attends them back again."

2. Psophia undulata, or undulated trumpeter, is about the size of a goose. The upper part of the body is of a pale reddish brown-colour, beautifully undulated with black. The head is adorned with a dependant crest. On each side of the neck, beneath the ears, begins a list of black, widening as it descends, and meeting on the lower part before, where the feathers become greatly elongated, and hang loosely down. The under parts are generally white; the legs are of a dusky blue colour, like the bill. It is a native of Africa. Mr. Latham's specimen came from Tripoli.

PSORA. See MEDICINE.

PSORALEA, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is powdered with callous points, and as long as the monospermous legumen. There are 33 species. The most remarkable are:

1. The pinnata, or pinnated psoralea, with a woody soft stem, branching five or six feet high, pinnated leaves of three or four pair of narrow lobes terminated by an odd one, and at the axillas close-sitting blue flowers with white keels. It is a native of Ethiopia.

2. The bituminosa, or bituminous trifoliate psoralea, rises with a shrubby stalk, branching sparingly about two or three feet high, with ternate or three-lobed leaves of a bituminous scent, and blue flowers in close heads. It grows in Italy and in France.

3. The aculeata, or aculeated prickly psoralea, rises with a shrubby branching stem three or four feet high, with ternate leaves, having wedge-shaped lobes, terminating in a recurved sharp point, and the branches terminated by roundish heads of blue flowers. It grows in Ethiopia. These plants flower here every summer; the first sort the greatest part of that season, and the others in July and August; all of which are succeeded by seeds in autumn. Keep them in pots in order for removing into the greenhouse in winter. They are propagated by seeds, sown in a hotbed in the spring; and when the plants are two or three inches high, prick them in separate small spots, and gradually harden them to the open air, so as to bear it fully by the end of May or beginning of June. They may also be propagated by cuttings any time in summer, planted in pots, and plunged in a little heat; or covered close with hand-glasses, shaded from the sun, and watered.

PSYCHOTRIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The calyx is quinquedentate, persisting, and crowning the fruit; the corolla is tubulated; the berry globose, with two hemispherical sulcated seeds. The species are 39, chiefly shrubs of the West Indies.

PTARMICA, *sneeze-wort*, a genus of the syngenesia polygamia superflua class of plants, the compound flower whereof is radiated, and the peculiar hermaphrodite ones of a funnel-shape, with a patulous quinquefid limb; the stamina are five capillary very short filaments; and the seeds, one of which succeeds each hermaphrodite flower, are contained in the cup. The leaves of this plant are sometimes used in sallad; and when dried and reduced to powder, they make a good sternutatory.

PTELEA, *shrub-trefoil*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx quadripartite inferior; the fruit is monospermous, with a roundish membrane in the middle.

There is one species, viz. the trifoliata, or Carolina shrub-trefoil. It has a shrubby upright stem, dividing into a branchy head eight or ten feet high, covered with a smooth purplish bark, trifoliate leaves, formed of oval spear-shaped folioles, and the branches terminated by large bunches of greenish-white flowers, succeeded by roundish, bordered capsules. It is a hardy deciduous shrub, and a proper plant for the shrubbery and other ornamental plantations to increase the variety. It is propagated by seeds, layers, and cuttings.

PTERIS, a genus of the order of filices, in the cryptogamia class of plants. The fructifications are in lines under the margin. There are 34 species. The most remarkable is the aquilina, or common female fern. The root of this is viscid, nauseous and bitterish; and like all the rest of the fern tribe, has a salt, mucilaginous taste. It creeps under the ground in some rich soils to the depth of five or six feet, and is very difficult to be destroyed. Frequent mowing in pasture-grounds, plentiful dunging in arable lands, and above all, pouring urine upon it, are the most approved methods of killing it. It has, however, many good qualities to counterbalance the few bad ones. Fern cut while green, and left to rot upon the ground, is a good improver of land; and its ashes, if burnt, will yield the double quantity of salt that most other vegetables will. Fern is also an excellent manure for potatoes; for if buried beneath their roots, it never fails to produce a good crop. Its astringency is so great, that it is used in many places abroad in dressing and preparing kid and chamois leather. In several places in the north, the inhabitants mow it green, and, burning it to ashes, make those ashes up into balls, with a little water, which they dry in the sun, and make use of them to wash their linen instead of soap. In many of the Western Isles, the people gain a very considerable profit from the sale of the ashes to soap and glass-makers. In Glen Elg in Inverness-shire, and other places, the people thatch their houses with the stalks of this fern, and fasten them down with ropes made either of birch, bark, or heath. Swine are fond of the roots, especially if boiled in their wash. In some parts of Normandy we read that the poor have been reduced to the miserable necessity of mixing them with their bread; and in Siberia, and some other northern countries, the inhabitants brew them in their ale, mixing one-third of the roots to two-thirds of malt. The antients used the root of this fern, and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds, arising from obstructions of the viscera and the spleen. Some of the moderns have given it a high character in the same intentions, but it is rarely used in the present practice. The country-people, however, still continue to retain some of its antient uses; for they give the powder of it to destroy worms, and look upon a bed of the green plant as a sovereign cure for the rickets in children.

PTEROCARPUS, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is quinquedentate; the capsule falcated, filiaceous, varicose. The seeds are few and solitary. There are six species. The most remarkable are:

1. Draco. 2. Ecastaphyllum. 3. Lunatus. And, 4. Santalinus. This last is called red saunders; and the wood is brought from the East Indies in large billets, of a compact texture, a dull red, almost blackish colour on the outside, and a deep brighter red within. This wood has no manifest smell, and little or no taste.

The principal use of red saunders is as a colouring drug; with which intention it is employed in some formulæ, particularly in the tinctura lavendulæ composita. It communicates a deep red to rectified spirit, but gives no tinge to aqueous liquors; a small quantity of the resin, extracted by means of spirit, tinges a large one of fresh spirit of an elegant blood-red. There is scarcely any oil, that of lavender excepted, to which it communicates its colour. Geoffroy and others take notice, that the Brazil woods are sometimes substituted for red saunders; and the college of Brussels are in doubt whether all that is sold among them for saunders is not really a wood of that kind.

PTERONIA, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is full of multipartite bristles; the pappus a little plumy; the calyx imbricated. There are 18 species, shrubs of the Cape.

PTEROSPERMUM, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is quinquepartite; the corolla consists of five oblong spreading petals. The filaments are about fifteen, which unite towards the base into a tube. The style is cylindrical; the capsule is oval, woody, and quinquelocular, each of which are bivalved, containing many oblong, compressed, and winged seeds. There are two species, natives of the East Indies; the wood of which is very hard, and very like that of the holly-tree.

PTEROTRACHEA, a genus of the vermes mollusca. Body detached, gelatinous, with a moveable fin at the abdomen or tail; eyes two, placed within the head. There are four species, that inhabit chiefly the Archipelago.

PTINUS, a genus of insects belonging to the order coleoptera. The generic character is, antennæ filiform, with the three last joints largest; thorax roundish, without distinct margin, receiving occasionally the head.

The genus ptinus, like that of dermestes, consists of small insects, which, in general, have similar habits, living both in their larva and complete state among dry animal substances; and some species in dry wood, committing great havoc among the older articles of furniture, which they pierce with innumerable holes, thus causing their gradual destruction.

To this genus belongs the celebrated insect, distinguished by the title of the death-watch, or ptinus fatidicus. Among the popular superstitions which the almost general illumination of modern times has not been able to obliterate, the dread of the death-watch may well be considered as one of the most predominant, and still continues to disturb the habitations of rural tranquillity with groundless fears and absurd apprehensions. It is not indeed to be imagined that those who are engaged in the more important cares of providing the immediate necessaries of life, should have either leisure or inclination to investigate with philosophic exactness the causes of a particular sound; yet it must be allowed to be a very singular circumstance that an animal so common should not be more universally known, and the peculiar noise which it occasionally makes be more universally understood. It is chiefly in the advanced state of spring that this alarming little animal commences its sound, which is no other than the call or signal by which the male and female are led to each other, and which may be considered as analogous to the call of birds, though not owing to the voice of the insect, but to its beating on any hard substance with the shield or fore-part of its head. The prevailing number of distinct strokes which it beats is from seven to nine or eleven; which very circumstance may perhaps still add in some degree to the ominous character which it bears among the vulgar. These sounds or beats are given in pretty quick succession, and are repeated at uncertain intervals; and in old houses where the insects are numerous, may be heard at almost every hour of the day, especially if the weather is warm. The sound exactly resembles that which may be made by beating moderately hard with a nail on a table. The insect is of a colour so nearly resembling that of decayed wood, viz. an obscure greyish brown, that it may for a considerable time elude the search of the enquirer. It is about a quarter of an inch in length, and is moderately thick in proportion, and the wing-shells are marked with numerous irregular variegations of a lighter or greyer cast than the ground-colour.

We must be careful not to confound this animal, which is the real death-watch of the vulgar, emphatically so called, with a much smaller insect of a very different genus, which makes a sound like the ticking of a watch, and continues it for a long time without intermission. It belongs to a totally different order, and is the termes pulsatorium of Linnæus.

We cannot conclude this slight account of the death-watch without quoting a sentence from that celebrated work the Pseudodoxia Epidemica of the learned sir Thomas Brown, who on this subject expresses himself in words like these: "He that could eradicate this error from the minds of the people, would save from many a cold sweat the meticulous heads of nurses and grandmothers."

A very destructive little species of ptinus is often seen in collections of dried plants, &c. remarkable for the ravages it commits both in its larva and perfect state. The larva resembles that of a beetle in miniature, being about the eighth of an inch long, and of a thickish form, lying with the body bent, and is of a white colour. The perfect insect is very small, measuring only about the tenth of an inch, and is slender, of a pale yellowish chesnut-colour, appearing, when magnified, beset with small short hairs, with the wing-covers finely striped by rows of small impressed points or dots. The ravages of the larva are most remarkable during the summer.

The ptinus fur of Linnæus is another very destructive species. Its length is somewhat more than the tenth of an inch, and its colour pale chesnut-brown, sometimes marked on the wing-covers by a pair of greyish bands; the antennæ are rather long and slender; the body remarkably convex; and the thorax, when magnified, appears to have a projecting point on each side. Its larva resembles that of the preceding species, and is found in similar situations.

PTOLEMAIC, or *Ptolemean system of astronomy*, is that invented by Claudius Ptolemæus, a celebrated astronomer and mathematician of Pelusium in Egypt, who lived in the beginning of the second century of the Christian æra.

This hypothesis supposes the earth immoveably fixed in the centre, not of the world only, but also of the universe; and that the sun, the moon, the planets, and stars, all move about it from east to west, once in 24 hours, in the order following, viz. the moon next to the Earth, then Mercury, Venus, the Sun, Mars, Jupiter, Saturn, the fixed stars, the first and second crystalline heavens, and above all, the fiction of their primum mobile.

PUBES. See ANATOMY.

PUCERON. See APHIS.

PULEX, the *flea*, a genus of insects of the order aptera. The generic character is, legs six, formed for leaping; eyes two; antennæ filiform; mouth furnished with an inflected, setaceous snout, concealing a piercer; abdomen compressed.

This genus is one of the most singular in the order aptera. The pulex irritans, or common flea, so well known in its complete state in every region of the globe, is remarkable for undergoing the several changes experienced by the major part of the insect race of other tribes; being produced from an egg, in the form of a minute worm or larva, which changes to a chrysalis, in order to give birth to the perfect animal. The female flea deposits, or rather drops, her eggs at distant intervals, in any favourable situation: they are very small, of an oval shape, of a white colour, and a polished surface. From these, in the space of six days, are hatched the larvæ, which are destitute of feet, of a lengthened worm-like shape, beset with distant hairs, and furnished at the head with a pair of short antennæ or tentacula, and at the tail with a pair of slightly curved forks or holders. Their colour is white, with a reddish cast, and their motions quick and tortuous. These larvæ are very frequently found in the nests of various birds, and, in particular, of pigeons, where they fasten occasionally to the young brood, and saturate themselves with blood. In the space of ten or twelve days, they arrive at their full growth, when they usually measure near a quarter of an inch in length. At this period they cease to feed, and, casting their skin, change into the state of a chrysalis, which is of a white colour, and of an oval shape, with a slightly pointed extremity, and exhibits the immature limbs of the included insect. The larvæ are said to spin themselves up in an oval cotton-like covering before they undergo their change. This, however, is not always the case. After lying for the space of twelve days in chrysalis, the complete insect emerges in its perfect form. It now begins to exert its lively motions; and employs the sharp proboscis with which nature has furnished it, in order to obtain nourishment from the first man, bird, or quadruped, to which it can gain access. The time required for the evolution of this animal varies considerably according to the season of the year, and in the winter months is of much longer duration than the period above-mentioned; the egg scarcely hatching under twelve days, and the larvæ lying nearly twice the usual time in chrysalis.

Among the chief singularities observable in the structure of the flea, may be noticed the extraordinary situation of the first pair of legs, which, instead of being placed beneath the thorax, as in most other insects, are situated immediately beneath the head; the antennæ are short, hairy, and consist of five joints; and at a small distance beneath there is placed the proboscis, which is strong, sharp-pointed, tubular, and placed between a pair of jointed guards or sheaths, which are still farther strengthened at the base by a pair of pointed scales; the eyes are large, round, and black. The general appearance of the animal is too well known to require particular description: it may only be necessary to observe, that the male is considerably smaller than the female, with the back rather sinking than convex, as it always is in the female insect. Nothing can exceed the curious disposition and polished elegance of the shelly armour with which the animal is covered, nor can the structure of the legs be contemplated without admiration.

Though it would perhaps be difficult to prove that there exists in Europe more than one genuine species of flea, yet it is certain that some permanent varieties or races may be traced, which a practised eye can readily distinguish from the common domestic kind. Of these the most remarkable seems to be that infesting some of the smaller quadrupeds, and particularly mice and bats. This variety is of a more slender form than the common flea, and of a paler colour, differing from that insect nearly in the same proportion that a greyhound does from the more common race of dogs.

Pulex penetrans, or chigger, is a native of South America and the West Indian islands. According to Catesby's microscopic figure of this insect, it may properly be arranged under the present genus; but it is probable, from the different descriptions of authors, that some insects of the genus acarus, which excite similar swellings under the skin, have been confounded with it under the general name of chigger or chigoe. Catesby's account runs as follows:

" It is a very small flea, that is found only in warm climates. It is a very troublesome insect, especially to negroes, and others that go barefoot and are slovenly. They penetrate the skin, under which they lay a bunch or bag of eggs, which swell to the bigness of a small pea or tare, and give great pain till taken out; to perform which great care is required, for fear of breaking the bag, which endangers a mortification, and the loss of a leg, and sometimes life itself. This insect, in its natural size, is not above a fourth part so big as the common flea. From the mouth issues a hollow tube like that of the common flea, between a pair of antennæ. It has six jointed legs, and something resembling a tail. The egg is so small as to be scarcely discerned by the naked eye. These chegoes are a nuisance to most parts of America between the tropics."

PULLEY. See Mechanics.

PULMONARIA, *lungwort*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla is funnel-shaped, with its throat pervious; the calyx is prismatic and pentagonal. There are seven species, of which the most remarkable is the officinalis, common spotted lungwort, or Jerusalem cowslip. This is a native of woods and shady places in Italy and Germany, but has been cultivated in Britain for medical use. The leaves are of a green colour, spotted with white; and of a mucilaginous taste, without any smell. They are recommended in phthisis, ulcers of the lungs, &c. but their virtues in these diseases are not warranted by experience.

PULSATILLA. See Anemone.

PULSE, in the animal economy, denotes the beating or throbbing of the heart and arteries. See Physiology.

Pulse. See Legumen.

PULTENÆA, a genus of the class and order decandria monogynia. The calyx is five-toothed; corolla papilionaceous; legume one cell, two-seeds. There are six species, shrubs of New Holland.

PUMICE-STONE, or *porous glasses*. When the compact glasses are exposed to the heat of our furnaces, they emit a great number of air-bubbles, which renders them porous: such is the origin of pumice. It has the same base as compact glass. The texture is fibrous; the fibres have a silky lustre. Colours various; white, brown, yellow, black. Before the blow-pipe, they melt into a white enamel. According to Klaproth, the pumice consists of

77.50	silica
17.50	alumina
1.75	oxide of iron
3.00	potass
99.75.	

See Fulmination.

PUMP, an hydraulic machine for raising water by means of the pressure of the atmosphere. It would be an entertaining and not an uninstructive piece of information to learn the progressive steps by which the ingenuity of man has invented the various methods of raising water. A pump must be considered as the last step of this progress. Common as it is, and overlooked even by the curious, it is a very abstruse and refined invention. Nothing like it has been found in any of the rude nations whom the Europeans have discovered, either in the new continent of America or the islands of the Pacific Ocean. Nay, it was unknown in the cultivated empire of China at the time of our arrival there by sea; and it is still a rarity every where in Asia, in places unfrequented by the Europeans. It does not appear to have been known by the Greeks and Romans in early times; and perhaps it came from Alexandria, where physical and mathematical science was much cultivated by the Greek school under the protection of the Ptolemies. The performances of Ctesibius and Hero are spoken of by Pliny and Vitruvius as curious novelties. There are two sorts of pumps, which essentially differ; and all the varieties are but modifications of these. One has a piston with a perforation and valve; the other has a solid piston: to the former is given the name of the common sucking-pump; the latter is denominated the forcing-pump.

Fig. 1. represents the common sucking-pump. AA is a cylinder of cast iron, bored smooth withinside; it has a flanch at the top, by which it is screwed to the wooden cistern B, which conveys the water away from the pump. It has also a flanch D at its lower end, to screw on the pipe E, which brings the water to the pump. In the same flanch is a pair of valves, *aa*; and the bucket or piston F, which slides within the barrel, has another similar pair of valves in it. This bucket is screwed to an iron rod G, which is moved up and down by some machine. When the bucket F descends, its valves *bb* open as in the figure, and allow the water which fills the barrel to pass through them. When the bucket arrives at the bottom of the barrel, it is drawn up again; and as the valves shut, and prevent the water from returning through the bucket, it lifts all the water contained in the barrel into the cistern B. At the same time the bucket, in rising, makes a vacuum beneath it: the pressure of the atmosphere upon the surface of the water in the well, causes it to mount up through the pipe E, open the valves *aa*, and fill the barrel AA. When the bucket begins to descend, the column of water beneath it descends also, till it is stopped by the shutting of the valves *aa*; the valves *bb* then open, and allow the water to pass through as before.

Fig. 2 is a forcing-pump. In this the barrel AA is screwed upon a square box BB, which has a pair of valves *aa* at the top of the pipe C, bringing water from the well; and another similar pair at the lower end of the pipe D, which is likewise screwed to the square box. The plunger E is solid: when it is drawn up it makes a vacuum in the barrel, and draws the water up through the valves *aa* from the well to fill the barrel. The plunger is then forced down, the valves *aa* shut, and as the water has no other way out of the box, it passes through *bb* up the pipe D. The plunger is then drawn up, the valves *bb* shut, and *aa* open to supply the barrel as before.

Fig. 3 is a lift-pump. The barrel AA is screwed by its top to a shorter barrel H, from which the crooked pipe B proceeds. A cover *h* is screwed over the top of the barrel H, with a stuffing-box in the middle of it; which is a box containing cotton, or other light substances, through which the piston-rod E passes. The piston F has two valves *bb* in it, similar to fig. 1; and at the bottom of the barrel are two valves similar to *aa* (fig. 1). When the piston descends, the lower valves prevent the water from going out of the barrel: and the valves *bb* open, to let the water press through them. When the piston returns, the valves in it shut, and it raises the water through the pipe B; the stuffing-box preventing its getting out at the top of the barrel, by the side of the piston-rod, as in fig. 1; and at the same time, by making a vacuum beneath it, filling the barrel through the lower valves in the same manner as the sucking-pump. The piston then descends, the lower valves shut, and *bb* open as before. In all the figures, W represents a hole in the bottom of the pump, to get at the valves to repair them; and when the pump is at work, a cover is screwed over it, as shewn in fig. 3. Pumps constructed as in the drawing are seldom less than one or two feet in the bore of the barrel.

The common sucking-pump may, by a small addition, be converted into a lifting-pump, fitted for propelling the water to any distance, and with any velocity. Fig. 4, is a sucking-pump on a small scale, whose working-barrel AB has a lateral pipe C, connected with it close to the top. This terminates in a main or rising pipe, furnished or not with a valve. The top of the working-barrel AB is shut by a strong plate, having a hollow neck terminating in a small flanch. The piston-rod passes through this neck, and is nicely turned and polished. A number of rings of leather are put over the rod, and strongly compressed round it by another flanch and several screwed bolts. By this contrivance, the rod is closely grasped by the leathers; but may be easily drawn up and down, while all passage of air or water is effectually prevented. The piston is perforated, and furnished with a valve opening upwards. There is also a valve, T, on the top of the suction-pipe; and it will be of advantage, though not absolutely necessary, to put a valve L at the bottom of the rising-pipe. Now, suppose the piston at the bottom of the working-barrel; when it is drawn up, it tends to compress the air above it, because the valve in the piston remains shut by its own weight. The air, therefore, is driven through the valve L, into the rising-pipe, and escapes. In the mean time, the air which occupied the small space between the piston and the valve T, expands into the upper part of the working-barrel; and its elasticity is so much diminished thereby, that the atmosphere presses the water of the cistern into the suction-pipe, where it rises until an equilibrium is again produced. The next stroke of the piston downwards, allows the air which had come from the suction-pipe into the barrel during the ascent of the piston, to get through its valve. Upon drawing up the piston, the air is also drawn off through the rising-pipe. Repeating this process, brings the water at last into the working-barrel, and it is then driven along the rising-pipe by the piston.

This is one of the best forms of a pump. The rarefaction may be very perfect, because the piston can be brought so near to the bottom of the working-barrel: and for forcing water in opposition to great pressures, it appears preferable to the common forcing-pump; because in that, the piston-rod is compressed and exposed to bending, which greatly hurts the pump, by wearing the piston and barrel on one side. This soon renders it less tight, and much water squirts out by the sides of the piston. But in this pump the piston-rod is always drawn, or pulled, which keeps it straight, and rods exert a much greater force in opposition to a pull than to compression. The collar of leather round the piston-rod, is found by experience to be very impervious to water; and though it needs but little repair, yet the whole is very accessible; and in this respect much preferable to the common pump, in deep mines, where every fault of the piston obliges us to draw up some hundred feet of piston-rods. By this addition too, any common pump, for the service of a house, may be converted into an engine for extinguishing fire, or may be made to convey the water to every part of the house; and this without hurting or obstructing its common uses. All that is necessary, is to have a large cock on the upper part of the working-barrel, opposite to the lateral pipe in this figure. This cock serves for a spout, when the pump is used for common purposes; and the merely shutting this cock, converts the whole into an engine for extinguishing fire, or for supplying distant places with water. It is scarcely necessary to add, that, for these services, it will be requisite to connect an air-vessel with some convenient part of the rising-pipe, in order that the current of water may be continual.

It is of considerable importance, that as equable a motion as possible is produced in the main-pipe, which diminishes those strains which it is otherwise liable to. The application of an air-vessel at the beginning of the pipe, answers this purpose. In great works, it is usual to effect this by the alternate action of two pumps. It will be rendered still more uniform, if four pumps are employed, succeeding each other at the interval of one quarter of the time of a complete stroke.

But ingenious men have attempted the same thing with a single pump; and many different constructions for this purpose have been proposed and executed. Fig. 5, represents one of the best. It consists of a working-barrel, *ab*, closed at both ends; the piston *c* is solid, and the piston-rod passes through a collar of leathers at the top of the barrel. This barrel communicates laterally with two pipes, *n* and *k*, the communications being as near to the top and bottom of the barrel as possible. At each of the communications are two valves, opening upwards. The two pipes unite in a larger rising-pipe at *b*, which bends a little back, to give room for the piston-rod. Suppose the piston down close to the entry of the lateral pipe *h*; when it is drawn up, it compresses the air above it, and drives it through the valve in the pipe *k*, whence it escapes through the rising-pipe; at the same time it rarefies the air below it. Therefore the weight of the atmosphere shuts the valve *m*, and causes the water in the cistern to rise through the valve *n*, and fill the lower part of the pump. When the piston is pushed down again, this water is first driven through the valve *m*, because *n* immediately shuts; and then most of the air which was in this part of the pump at the beginning, goes up through it, some of the water coming back in its stead. In the mean time, the air which remained in the upper part of the pump after the ascent of the piston, is rarefied by its descent; because the valve *o* shuts as soon as the piston begins to descend, the valve *p* opens, the air in the suction-pipe *h* expands into the barrel, and the water rises into the pipes by the pressure of the atmosphere. The next rise of the piston must bring more water into the lower part of the barrel, and must drive a little more air through the valve *o*, namely, part of that which had come out of the suction-pipe *h*; and the next descent of the piston must drive more water into the rising-pipe *k*, and along with it, most, if not all, of the air which remained below the piston, and must rarefy still more the air remaining above the piston; and more water will come in through the pipe *h*, and get into the barrel. It is evident, that a few repetitions will at last fill the barrel on both sides of the piston with water. When this is accomplished, there is no difficulty in perceiving how, at every rise of the piston, the water of the cistern will come in by the valve *n*, and the water in the upper part of the barrel will be driven through the valve *o*; and in every descent of the piston, the water of the cistern will come into the barrel by the valve *p*, and the water below the piston will be driven through the valve *m*; and thus there will be a continual influx into the barrel through the valves *n* and *p*, and a continual discharge along the rising-pipe *l* through the valves *m* and *o*.

This machine is certainly equivalent to two forcing-pumps, although it has but one barrel and one piston; but it has no sort of superiority. It is not even more economical, in most cases; because, probably, the expence of the additional workmanship will equal that of the barrel and piston, which is saved. There is, indeed, a saving in the rest of the machinery, because one lever produces both motions. It therefore cannot be called inferior to two pumps; and there is undoubtedly some ingenuity in the contrivance.

Fig. 6, is another pump for furnishing a continued stream, invented by Mr. Noble. AB, the working-barrel, contains two pistons, C and B, which are moved up and down alternately by the rods fixed to the lower F. The rod of the piston B, is carried through the piston or bucket C. This pump is very simple in its principle, and may be executed at little expence.

The pump invented by M. De la Hire, raises water equally quick by the descent as by the ascent of the piston in the pump-barrel.

AA (fig. 7), is a well, in which the lower ends of the pipes B and C are placed. D is the pump-barrel, into the lowermost end of which the top of the open pipe B is soldered, and in the uppermost end the hollow pipe S is soldered, which opens into the barrel; and the top of the pipe C is soldered into that piece. Each of these pipes has a valve on its top, and so have the crooked pipes E and F, whose lower ends are open into the pump-barrrel, and their upper ends into the box G. L is the piston-rod, which moves up and down through a collar of leather in the neck M; K is a solid plunger, fastened to the rod or spear L; the plunger never goes higher than K, nor lower than D; so that from K to D is the length of the stroke.

As the plunger rises from D to K, the atmosphere (pressing on the surface of the water AA in the well) forces the water up the pipe B, through the valve *b*, and fills the pump-barrel with water up to the plunger; and during this time, the valves *e* and S lie close and air-tight on the tops of the pipes E and C.

When the plunger is up to its greatest height, at K, it stops there for an instant, and in that instant the valve *b* falls, and stops the pipe B at top. Then, as the plunger goes down, it cannot force the water between K and D back through the close valve *b*; but forces all that water up the crooked pipe E, through the valve *e*, which then opens upward by the force of the water; and this water, after having filled the box G, rises into the pipe N, and runs off by the spout at O.

During the descent of the plunger K, the valve *f* falls down, and covers the top of the crooked pipe F; and the pressure of the atmosphere on the well AA forces the water up the pipe C, through the valve S, which then opens upward by the force of the ascending water; and this water runs from S into the pump-barrel, and fills all the space in it above the plunger.

When the plunger is down to its lowest descent at D, and stops there for an instant, in that instant the valve S falls down, and shuts the top of the pipe C; and then, as the plunger is raised, it cannot force the water above it back through the valve S, but drives all that water up to the crooked pipe F, through the valve *f*, which opens upward by the force of the ascending water; which water, after filling the box G, is forced up from thence into the pipe N, and runs off by the spout at O.

And thus, as the plunger descends, it forces the water below it up the pipe E; and as it ascends, it forces the water above it up the pipe F: the pressure of the atmosphere filling the pump-barrel below the plunger, through the pipe B, while the plunger ascends; and filling the barrel with water above the plunger, through the pipe C, as the plunger goes down.

Thus there is as much water forced up the pipe N, to the spout O, by the descent of the plunger, as by its ascent; and, in each case, as much water is discharged at O, as fills that part of the pump-barrel which the plunger moves up and down in.

On the top of the pipe O is a close air-vessel P. When the water is forced up above the spout O, it compresses the air in the vessel P; and this air, by the force of its spring acting on the water, causes the water to run off by the spout O, in a constant and (very nearly) equal stream.

Whatever the height of the spout O is above the surface of the well, the top S, of the pipe C, must not be 32 feet above that surface; because if that pipe could be entirely exhausted of air, the pressure of the atmosphere in the well would not force the water up the pipe to a greater height than 32 feet; and if S is within 24 feet of the surface of the well, the pump will be so much the better.

As the collar of leathers within the neck M, is apt to dry and shrink when the pump is not used, and consequently to let air get into the pump-barrel, which would stop the operation of the atmosphere in the pipe C; collars of old hats might be used instead of leathers, as they would not be liable to that inconvenience.

It matters little what the size of the pipe N is, through which the water is forced up to the spout; but a great deal depends on the size of the pump-barrel; and according to the height of the spout O, above the surface of the well, the diameter of the bore of the barrel should be as follows:

For 10 feet high the bore should be 6.9 inches; for 15 feet 5.6; for 20 feet 4.9; for 25 feet 4.4; for 30 feet 4.0; for 35 feet 3.7; for 40 feet 3.5; for 45 feet 3.3; for 50 feet 3.1; for 55 feet 2.9; for 60 feet 2.8; for 65 feet 2.7; for 70 feet 2.6; for 75 feet 2.5; for 80 feet 2.5 will do; for 85 feet 2.4; for 90 feet 2.3; for 95 feet 2.2; and for 100 feet, the diameter of the bore should not exceed 2.1 or 2.2 inches at most. If these proportions are attended to, a man of common strength may raise water 100 feet high by one pump, as easily as he could raise it ten feet high by another.

In this pump the pipes B and C seem to be rather too small; which will cause the water rising in them to have a great deal of friction from the quickness of its motion; and whoever makes such a pump, will find it very difficult to make the leather in the neck M water-tight, so that no water shall be forced out that way when the piston is drawn up.

The hair-rope machine for raising water was invented by sieur Vera:

A (fig. 8), is a wheel four feet over, having an axis and a winch; CC, a hair-rope, near one inch diameter; D, a reservoir to collect the water: E, a spout to convey the water from the reservoir; G, the surface of the water in the well; I, a pulley under which the rope runs, in order to keep it tight.

When the handle is turned about with a considerable velocity, the water which adheres to the rope, in wells of no great depth, is very considerable: the rope thus passes through the tubes in D, which, being five or six inches higher than the bottom of the reservoir, hinders the water from returning back into the well, and is conveyed in a continual stream through the spout E. Some of the above engines, improved by Mr. Stamford, have raised a greater quantity of water than any person unskilful in hydraulics could suppose, in the same time, from such a simple contrivance.

The chain-pump consists of two square, or cylindrical barrels, through which a chain passes, having a great number of flat pistons, or valves, fixed upon it at proper distances. This chain passes round a kind of wheel-work, fixed at one end of the machine. The teeth of this are so contrived as to receive one-half of the flat pistons, which go free of the sides of the barrel by near a quarter of an inch, and let them fold in, and they take hold of the links as they rise. A whole row of the pistons, which go free of the sides of the barrel by near a quarter of an inch, are always lifting when the pump is at work; and as this machine is generally worked with briskness, they bring up a full bore of water in the pump. It is wrought either by one or two handles, according to the labour required.

The many fatal accidents which happen to ships from the choking of their pumps, makes it an important object, in naval affairs, to find some machine for freeing ships from water, not liable to so dangerous a defect. The chain-pump being found least exceptionable in this respect, was adopted in the British navy; but the chain-pump itself is not free from imperfections. If the valves are not well fitted to the cylinder through which they move, much water will fall back; if they are well fitted, the friction of many valves must be considerable, besides the friction of the chain round the sprocket-wheels, and that of the wheels themselves. To which may be added, the great wear of leathers, and the disadvantage which attends the surging and breaking of the chain. The preference, therefore, which has been given to chain-pumps over those which work by the pressure of the atmosphere, must have arisen from one circumstance, that they have been found less liable to choke.

In point of friction, of coolness, and of cheapness, the sucking-pump has so evidently the advantage over the chain-pump, that it will not fail to gain the preference, whenever it shall be no longer liable to be choked with gravel and with chips.

Buchanan's pump, which, like the common pump, acts by the pressure of the atmosphere, is not liable to the defects incident to other pumps upon that principle, being essentially different from any now in use.

The principal object of its invention was to remove the imperfection of its choking. In attaining this important end, a variety of collateral advantages have also been produced, which enhance its utility.

The points in which it differs essentially from the common pump, and by which it excels, are, that it discharges the water below the piston, and has its valves lying near each other.

The advantages of this arrangement are, that the sand or other matter, which may be in the water, is discharged without injuring the barrel or the piston-leathers; so that besides avoiding unnecessary wear and tear, the power of the pump is preserved, and not apt to be diminished or destroyed in moments of danger, as is often the case with the common and chain pumps: that the valves are not confined to any particular dimensions, but may be made capable of discharging every thing that can rise in the suction-piece, without danger of being choked: that if there should happen upon any occasion to be an obstruction in the valves, they are both within the reach of a person's hand, and may be cleared at once, without the disjunction of any part of the pump: and that the pump is rendered capable of being instantaneously converted into an engine for extinguishing fire. Besides, it occupies very little space in the hold, and thus saves room for stowage.

But this pump is not confined to nautical uses alone; its adaptation extends to the raising of water in all situations, and with peculiar advantage where it happens to be mixed with sand or substances which destroy other pumps, as, for instance, in alum-works, in mines, in quarries, or in the clearing of foundations; and in its double capacity it will be very convenient in gardens, bleaching-grounds, in stable and farm yards, and in all manufactories, or other places, where there are a necessity for raising water and the risk of fire.

With all these advantages, it is a simple and durable pump, and may be made either of metal or wood at a moderate expence.

Fig. 9, is a vertical section of the pump, as made of metal, in which A is the suction-piece, B the inner valve, C the outer valve.

The valves are of the kind called clack-valves. Their hinges are generally made of metal, as being more durable than leather.

D is the working-barrel, E the piston, and G the spout.

The following parts are necessary only when the pump is intended to act as a fire-engine:

H an air-vessel, which is screwed like a hose-pipe, that it may, at pleasure, the more readily be fixed or unfixed.

There is a perforated stopple for the spout, made for receiving such pipes as are common to fire-engines. It is oval and tapered, and being introduced transversely, upon being pulled back becomes immediately tight.

These parts being provided, all that is necessary to make the pump act as a fire-engine after having been used as a sucking-pump, is to plug up the spout with the stopple.

No particular mode being essential in the working of this pump, it may, according to choice or circumstances, be wrought by all the methods practised with the common pump. In many cases, however, it may be advantageous to have two of them so connected, as to have an alternate motion; in which case, one air-vessel, and even one suction-piece, might serve both.

Its principles admit of various modifications; but as what is already mentioned may be sufficient to indicate its superiority over the common and chain pumps, and the advantages likely to result from its general use, a further detail is unnecessary.

To this we may add, that the testimonies of several navigators confirm in the fullest manner, the hopes that were conceived of its utility, and warrant the recommendation of it, as the best adapted for the purpose of any pump hitherto invented.

The great desideratum in a piston is, that it is as tight as possible, and has as little friction as is consistent with this indispensable quality.

The common form, when carefully executed, has these properties in an eminent degree, and accordingly keeps its ground amidst all the improvements which ingenious artists have made. It consists of a hollow cylinder, having a piece of strong leather fastened round it, to make it fit exactly the bore of the barrel, and a valve or flap to cover the hole through which the water rises. The greatest difficulty in the construction of a piston, is to give a passage through it for the water, and yet allow a firm support for the valve and fixture for the piston-rod. It occasions a considerable expence of the moving power to force a piston with a narrow perforation through the water lodged in the working-barrel. When we are raising water to a small height, such as 10 or 20 feet, the power so expended amounts to a fourth part of the whole, if the water-way in the piston is less than one-half of the suction of the barrel, and the velocity of the piston two feet per second, which is very moderate. There can be no doubt, therefore, that metal pistons are preferable, because their greater strength allows much wider apertures. For common purposes, however, they are made of wood, as elm or beech.

There are many ingenious contrivances to avoid the friction of the piston in the pumps; but this is of little importance in great works, because the friction which is completely sufficient to prevent all escape of water in a well-constructed pump, is but a very trifling part of the whole force.

In the great pumps which are used in mines, and are worked by a steam-engine, it is very usual to make the pistons and valves without any leather whatever. The working-barrel is bored truly cylindrical, and the piston is made of metal, of a size that will just pass along it without sticking. When this is drawn up with a velocity competent to a properly loaded machine, the quantity of water which escapes round the piston is insignificant. The piston is made without leathers; not to avoid friction, which is also insignificant in such works, but to avoid the frequent necessity of drawing it up for repairs through such a length of pipes.

If a pump absolutely without friction is wanted, the following seems preferable, for simplicity and performance, to any we have seen, when made use of in proper situations. Let NO (fig. 10), be the surface of the water in the pit, and K the place of delivering. The pit must be as deep in water as from K to NO. A is a wooden trunk, round or square, open at both ends, and having a valve, P, at the bottom. The top of this trunk must be in a level with K, and has a small cistern, F. It also communicates laterally with a rising-pipe G, furnished with a valve opening upwards. L is a beam of timber, so fitted to the trunk, as to fill it without sticking, and is of at least equal length. It hangs by a chain from a working-beam, and is loaded on the top with weights exceeding that of the column of water which it displaces.

Now, suppose this beam to descend from the position in which it is drawn in the figure; the water must rise all round it, in the crevice which is between it and the trunk, and also in the rising-pipe; because the valve P shuts, and O opens; so that when the plunger L has got to the bottom, the water will stand at the level of K. When the plunger is again drawn up to the top by the action of the moving power, the water sinks again in the trunk, but not in the rising-pipe, because it is stopped by the valve O. Then allowing the plunger to descend again, the water must again rise in the trunk to the level of K, and it must now flow out at K; and the quantity discharged will be equal to the part of the beam below the surface of the pit-water, deducting the quantity which fills the small space between the beam and the trunk. This quantity may be reduced almost to nothing; for if the inside of the trunk, and the outside of the beam, are made tapering, the beam may be let down till they exactly fit; and as this may be done in square work, a good workman may make it exceeding accurate. But, in this case, the lower half of the beam, and trunk, must not taper; and this part of the trunk must be of sufficient width round the beam, to allow free passage into the rising-pipe; or, which is better, the rising-pipe must branch off from the bottom of the trunk. A discharge may be made from the cistern F, so that as little water as possible may descend along the trunk when the piston is raised.

The requisites of a valve are, that it is tight, and of sufficient strength to resist the great pressures to which it is exposed; that it affords a free passage to the water; and that it does not allow much to go back whilst it is shutting. The clack-valve is of all others the most obvious and common. It consists merely of a leather flap covering the aperture, and having a piece of metal on the upper side, both to strengthen and to make it heavier, that it may shut of itself. Sometimes the hinge is of metal. The hinge being liable to be worn by such incessant motion; and as it is troublesome, especially in deep mines, and under water, to undo the joint of the pump, in order to put in a new valve; it is frequently annexed to a box like a piston, made a little conical on the outside, and dropt into a conical seat made for it in the pipe, where it sticks fast; and to draw it up again, there is a handle like that of a basket, fixed to it, which can be laid hold of by a long grappling-iron. The only defect of this valve is, that by opening very wide when pushed up by the stream of water, it allows a good deal to go back during its shutting again.

The butterfly-valve is free from most of these inconveniences, and seems to be the most perfect of the clack-valves. It consists of two semicircular flaps revolving round their diameters, which are fixed to a bar placed across the opening through the piston. Some engineers make their great valves of a pyramidal form, consisting of four clacks, whose hinges are in the circumference of the water-way, and which meet with their points in the middle, and are supported by four ribs, which rise up from the sides, and unite in the middle. This is a most excellent form, affording a more spacious water-way, and shutting very readily.

There is another form of a valve, called the button or tail valve. It consists of a plate of metal turned conical on the edge, so as exactly to fit the conical cavity of its box. A tail projects from the under side, which passes through a cross bar in the bottom of the box, and has a little knob at the end, to hinder the valve from rising too high. This valve, when nicely made, is unexceptionable. It has great strength, and is therefore proper for all severe strains; and it may be made perfectly tight by grinding. Accordingly, it is used in all cases where tightness is of indispensable consequence. It is most durable, and the only kind that will do for passages where steam or hot water is to pass through.

The pressure on the pipes in pump-work, is in proportion to the standing height of the fluid above the part considered; but the weight incumbent on the bucket (or moving valve) of a pump in action, is nearly proportionable to that of a column of water raised; for though the push of the atmosphere on the surface of the spring, when the bucket rises, is really equal to the weight of 33 feet of water; yet is this resistance counterbalanced exactly by the weight of the atmosphere, ever incumbent on the surface of the water thereby raised; so that in fact, all the advantage to be obtained by hydraulic machines, as well indeed as from all other pieces of mechanism whatever, is only the putting matters into a convenient method of being executed; and the performance depends on the moving power entirely, under the disadvantage of friction always against it.

A pump intended to raise water to any height whatever, will always work as easy, and require no greater power to give motion to the bucket, if both the valves are placed towards the bottom of the pipe, than if they were fixed 33 feet above the surface of the water.

The playing of the piston thus low in the pipe will, besides, prevent an inconvenience which might happen was it placed above, viz. in case of a leak beneath the bucket, which, in a great length of pipe, may very easily happen, the outward air getting through, would hinder the necessary rarefaction of the air in the barrel on moving the piston, and consequently the pump might fail in its operation. This can only effectually be prevented, by placing the pump-work in or near the water; in which case, should any leak happen upward, in will only occasion the loss of some of the water, without any other inconvenience; and the leather valves being kept under water, will always be found supple, pliant, and in condition to perform their office.

Placing the pump-work (that is, the valve and piston) pretty low and near together, will also prevent the inconvenience of not being able in all cases, to fetch up water from the spring by the ordinary pump, when of an equal bore, by reason of the shortness of the stroke; which therefore cannot rarefy the air sufficiently to bring the water up to the piston from the lower valve. For instance: Take a smooth-barrelled pump, 21 feet long, having its piston fetching, suppose a foot stroke, placed above, and the clack or fixed valve at the other end below. By the playing of the piston, admit it possible for water to rise 11 feet; or if you will, let water be poured on the clack, to the height of 11 feet, and refit the piston; there will remain still nine feet of air between it and the water, which cannot be sufficiently rarefied by a foot stroke to open the clack, or fetch up more water: for in this case the air can only be rarefied in the proportion of 9 to 10; whereas, to make a bare equilibrium with the atmosphere, it ought to be as 9 to $13\frac{1}{2}$; since, as 22 (or the complement of 11 to 33 feet of water, the weight of the whole atmosphere), is to 33 feet or the atmosphere, so is the interval spoken of, 9 to $13\frac{1}{2}$; to complete which, the stroke ought to be at least $4\frac{1}{2}$ feet long. However, by filling the whole void between the piston and clack at first with water, this last objection might be removed.

In some cases, the pump cannot be placed conveniently perpendicular to the well. For example: Being to raise water out of the well at A, by means of a pump at B (fig. 11), the best way will be to carry the barrel as low as the spring is, communicating therewith by means of the pipe at C. The bucket then playing in the barrel BC, will have the same effect as if the well was made perpendicular to the pump; because the water, by its proper weight, will always replenish BC.

And if it should happen, from some considerable impediment, that the barrel cannot get down to the well directly, it may be led about any other way for convenience. And then making the pipe of conveyance, E, less in diameter than the barrel, it will sooner be exhausted of air, by moving the piston; and the water will follow very briskly, as by the leaden pump at B.

It will, however, always be more easy to draw water with pipes that are large, and of an equal bore throughout, because the water will have a less velocity in them, and the friction will be in proportion less. Upon this account, the common pumps made by plumbers, do not work so easy as those bored out of trees; because, by making the pipe that brings up water from the spring much less than the bucket, they, as it were, wiredraw the water raised. If the barrel, for instance, is four inches in diameter, and the pipe of conduct one, it will in rising move sixteen times as fast through the latter as it will through the former; and at the expence of needless labour, as well as the great wear and friction of the machine.

In practice, however, it is generally observed, that such leaden pumps as work pleasantly, and are light on the hand, have the water-way in the sucking-pipe nearly equal to one-fourth of the area of the barrel; and accordingly, an inch-and-a-half pipe will pretty well supply a three-inch barrel; and a four-inch barrel should have a leading-pipe nearly two inches in diameter.

In forcing-pumps, it is of the utmost consequence to avoid all contractions in the pipes. The main which leads from the forcing-pumps, should be equal to the working-barrel. If it is only half the diameter, it has but one-fourth of the area; the velocity in the main is four times greater than that of the piston; and the force necessary for discharging the same quantity of water is sixteen times greater.

We shall, before we close the article on pumps, give an account of Mr. Boulton's apparatus raising water. The principle for action of this machinery may be illustrated in the following manner:

A horizontal pipe is formed of iron or any other substance sufficiently strong, expanding at one end like the mouth of a trumpet, and at the other furnished with a valve that may be opened or shut at pleasure; near this smaller extremity is let in a vertical pipe, at right angles to the horizontal one, furnished at the juncture with a valve opening upwards, and open at the other end. This machine is let down into a stream of water, so deep as to cover the horizontal pipe, the trumpet-like mouth of which is placed so as to meet the current: in this situation the valve being open, a current passes through the pipe, of equal velocity with the current of the stream; if the valve is then suddenly closed, the recoil of the current will force open the valve of the vertical pipe, through which will rush a column of water: the force of the recoil soon subsiding, the vertical column will press on the valve at its bottom, and cause it to close the end of the vertical pipe, in which the ascending column of water will be detained. The horizontal valve being then opened, the current will recommence through the horizontal pipe, and upon closing the valve a recoil will happen as before, and an additional quantity of water will rise in the vertical pipe: by a repetition of the above process, the water rising through the pipe will overflow into any vessel placed to receive the water, forming a perpetual pump. The contrivances by which this instrument is made to draw water, from a depth below that of the impelling current, and to raise it to any height, will be mentioned hereafter. The uses to which this engine may be applied, are serious; besides the raising of water for the use of brewers, &c. it may be employed in raising water from the sea for salt-work, in draining marshes and pumping ships, and supplying with water those canals that are carried over or by the side of rivers.

For the more clear description of this invention, it is proper to state its physical principle of action, as follows:

First, when water moves or runs through a pipe, or close channel, or tube, if the end at which the water issues is suddenly stopped, the water will (by its acquired motion, momentum, or impetus) act upon the sides or circumference of the pipe; which being supposed strong enough to resist that impetus, the water will issue, with violence or velocity, at any aperture which may exist in or near the shut end of the pipe; and if to that aperture an ascending pipe is joined, a portion of water will rise in it.

Secondly, if a pipe, open at both ends, with an ascending pipe, such as has been described, is moved along, through standing water, in the direction of its length; upon shutting the hinder part of the pipe, a portion of the water will rise in the ascending-pipe, in the manner which has been stated in the former case, because the water is relatively in motion in respect to the pipe.

Thirdly, if in either of the cases recited, a pipe communicating with water at any lower level is joined to the main pipe, at or near the end at which water enters into it; and if, when such water has acquired motion relatively to that pipe (by the pipe being put in motion), the mouth or end at which the water enters is suddenly shut; the water, continuing its motion relatively to the pipe, will draw or suck up water from the lower level, through the ascending pipe, in order to fill up the vacuity occasioned by the water in the main pipes, persevering in its previous motion. What has been said respecting water, is also true in respect to other fluids.

The several cases above stated are resolvable into the general principle of the resistance which water and other fluids (and in general all bodies) make to a change of their state of rest, or motion, whether absolute or relative; and this principle has heretofore been applied to the raising of water only in a comparatively small and weak degree, and in a defective manner. But the improved apparatus continues its own action when once set going, unless some accident should stop or derange it; and is capable of raising water in great quantities, and to great heights, and they also differ, in other respects, from any thing which has been executed hitherto.

The nature of the said improved invention consists in using valves, of various constructions, instead of cocks, to open or shut the end, or ends, of a main pipe: and in the application of mechanism, or contrivances to assist in opening and shutting the valves at proper times; whereby water is raised independantly of any other power than a current of water through the main pipe.

The manner in which the said invention is to be performed, and the said improved apparatus and methods carried into effect, is as follows, viz.:

The first and most simple method is shewn in fig. 12, in which CC is the main pipe; DD the ascending pipe; A the valve of exit for the water to be raised; B the stop-valve; and E a weight which, by the lever F, attached to the axis G of the stop-valve B, opens it at the proper time. The said apparatus acts in the following manner: The main pipe being situated or fixed in a current or stream of water, either produced by the natural current or declivity of the river or other stream; or (which is preferable) by penning up water by a dam, weir, or bank, and by inserting the end of the main pipe through the said dam, weir, or bank, so as to obtain the greatest head or current of water the natural circumstances admit of; the stop-valve being opened to the position shewn in the figures, the water will run through the main pipe, until, by its action upon the stop-valve in its reclined position, it raises the weight, shuts the stop-valve, and the water, by its impetus or momentum, opens the exit-valve, and a portion of it rises in the ascending pipe; after which, the last-mentioned valve shuts, the water in the main pipe recoils, the weight descends and opens the stop-valves, and the water in the main-pipe regains its velocity. The like operations are repeated, and the water gradually rises in the ascending pipe, until it reaches its summit, and a quantity issues thence every stroke; which quantity is more or less, according as the height to which it is raised is less or greater.

J is an air-vessel, or reservoir of air, whereby the bursting of the pipes is prevented, or the danger thereof much diminished. Into this air-vessel the water from the main pipe enters through the exit-valve, and compresses the air in the vessel; which again, by its expansion or elasticity, acts upon the water (the regress of which is prevented by the shutting of the exit-valve); and the water rises through the ascending pipe, and by repeated strokes acquires the desired height.

The dimensions of the air-vessel, as well as its form and position, whether above, or laterally affixed to, the main pipe, are in great measure arbitrary; but its contents of air ought not to be much less than ten times the quantity of water to be raised through the ascending pipe each stroke; and if much larger still the better, the principal boundary being expence.

The stop-valve may be opened and shut, as has been described in the first method, by the mechanism shewn in the figure, or by any of the mechanism as shall be adapted to the opening of valves.

Another method is shewn by figs. 13, 14, and 15, and is applicable in cases where the water to be raised is below the level of the main pipe, and is to be discharged at that level: which cases occur in the drainage of marshy lands, where the action of the current of water of an embanked river, or other stream or source of water on a higher level, can be employed; or this method can be applied in raising water out of the holds of ships, or other vessels, by the motion of the vessel through the water.

This is explained by figs. 13, 14, and 15, where C is the main-pipe, A is the receiving valve, B the stop-valve, opening outwards, D the ascending or sucking pipe, J the air-vessel, and E the weight.

The water in the main pipe having acquired a proper velocity, the stop-valve shuts: the water in the main pipe, continuing its motion for a time, draws air out of the air-vessel. Then the momentum of the water in the main pipe being expended, the receiving valve shuts, and the stop-valve opens, the water regains its velocity, and the operation is repeated; and thus, in a few strokes, (the exhaustion increasing,) the air-vessel sucks up water from below, by the ascending pipe; and this being continued, the latter pipe fills by degrees to the top; after which, at every successive stroke, a portion of the water from below passes into the main pipe, and is carried off, with the upper water, to the place of delivery.

Air-Pump. See Pneumatics.

PUNCHEON, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraved either in creux or relievo, impressions of which are taken on metal, or some other matter, by striking it with a hammer on the end not engraved. There are various kinds of these puncheons used in the mechanical arts; such for instance are those of goldsmiths, cutlers, pewterers, &c. See also Coining.

Puncheon, in carpentry, is a piece of timber placed upright between two posts, whose bearing is too great, serving, together with them, to sustain some large weights. This term is also used for a piece of timber raised upright, under the ridge of a building, wherein the little forces, &c are jointed.

Puncheon is also used for the arbor, or principal part of a machine, whereon it turns vertically, as that of a crane, &c.

Puncheon is also a measure for liquids, containing a hogshead and one-third, or eighty-four gallons.

PUNICA, the *pomegranate-tree*: a genus of the monogynia order, in the icosandria class of plants, and in the natural method ranking under the 39th order, pomaceæ. The calyx is quinquefid, superior; there are five petals; the fruit is a multilocular and polyspermous apple.

The species are, 1. The granatum, or common pomegranate, with a tree stem, branching numerously all the way from the bottom, growing eighteen or twenty feet high; with spear-shaped, narrow, opposite leaves; and the branches terminated by most beautiful large red flowers, succeeded by large roundish fruit as big as an orange, having a hard rind filled with soft pulp and numerous seeds. There is a variety with double flowers, remarkably beautiful; and one with striped flowers. 2. The nana, or dwarf American pomegranate, with a shrubby stem, branching four or five feet high, with narrow short leaves, and small red flowers succeeded by small fruit; begins flowering in June, and continues till October. Both these species are propagated by layers: the young branches are to be chosen for this purpose, and autumn is the proper time for laying them.

The dried flowers of the double-flowered pomegranate are possessed of an astringent quality; for which reason they are recommended in diarrhœas, dysenteries, &c. where astringent medicines are proper. The rind of the fruit is also a strong astringent, and as such is occasionally made use of.

Pupil. See Anatomy, Optics, and Physiology.

PURCHASE, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance. A joint purchase is when two or more persons join together in the purchase. Purchasers of lands are to take notice of all charges thereon: there are, however, certain statutes to guard against fraudulent incumbrances. The court of chancery will relieve the purchaser of a term against a title that lay dormant, where money has been laid out on improvements.

Purchase, in the sea-language, is the same as draw in: thus when they say the capstan purchases apace, they only mean it draws in the cable apace.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God, in opposition to all traditions and human constitutions.

PURLINS, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

PURPLE, a colour composed of a mixture of red and blue.

A beautiful transparent purple for painting may be made by boiling four ounces of rasped Brasil-wood in a pint of stale beer, and half an ounce of logwood, till the liquor is heightened to the colour you desire, which may be known by dipping a piece of paper in it. If you find it too red, add a quarter of an ounce more of logwood, which will render it still deeper; and by this method you may bring it to any degree of purple, by putting either more or less logwood to the former composition, and fixing it with alum. This will produce such a clear purple, as no mixture of reds and blues will produce. Madam Mariana of Amsterdam, famous for painting in miniature, and for her excellent manner of illuminating prints, says, that the best purple that can be made, may be composed between the carmine and indigo; to strengthen which on the red side, you may add lake, between the lighter and darker part: and lake, when it is used in the same way on the foregoing purple, produces a very fine effect. See Dyeing.

PURPURA. See Murca.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it is well stowed, and keeps an account of what he every day delivers to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out; and that the paymaster or treasurer of the navy may issue out the disbursements, and pay off the men, according to his book.

PUS. The liquid called pus is secreted from the surface of an inflamed part, and usually moderates and terminates the inflammation. It assumes different appearances according to the state of the sore. When it indicates a healing sore, it is called healthy or good-conditioned pus. This liquid possesses the following properties:

It is of a yellowish-white colour, and of the consistence of cream. Its taste is insipid, and it has no taste when cold. Before the microscope it exhibits the appearance of white globules swimming in a transparent fluid.

It produces no change on vegetable blues. When exposed to a moderate heat it gradually dries, and assumes the appearance of horn. When exposed to destructive distillation, Bergman obtained first about one-fourth of the pus in the state of insipid water. On increasing the fire, a liquid came over containing abundance of ammonia, and accompanied by gaseous bodies, which were not examined. Some concrete carbonat of ammonia sublimed, accompanied by empyreumatic oil. A light brilliant coal remained of difficult incineration. The ashes gave traces of iron.

When pus is left exposed to the air, it gradually becomes acid, according to Hildebrant; and Haller affirms that it sometimes gives a red colour to litmus even when recent. When thrown into water it sinks to the bottom. When agitated, the mixture becomes milky; but the pus separates again when allowed to remain undisturbed. By repeated agitation, however, and especially by the application of heat, a milky liquid is obtained, which passes in that state through the filtre.

Alcohol thickens pus, but does not dissolve it; neither does pus unite with oils.

Sulphuric acid dissolves it, and forms a purple-coloured solution. When diluted with water, the dark colour disappears, and the pus separates; either sinking to the bottom, or rising to the surface, according to the quantity of water added, and the time that the solution has been allowed to stand. Diluted sulphuric acid does not act upon it.

Concentrated nitric acid effervesces with it, and forms a yellow solution, which when recent is decomposed by water, the pus subsiding in the state of grey flakes.

Muriatic acid dissolves it when heated, and the pus is separated by water.

With the fixed alkaline leys it forms a whitish ropy fluid, which is decomposed by water, the pus precipitating. Pure ammonia reduces it to a transparent jelly, and gradually dissolves a considerable portion of it.

When nitrat of silver is dropt into the solution of pus in water, a white precipitate separates. Nitrat and oxymuriat of mercury occasion a much more copious flaky precipitate.

Such are the properties of healthy pus hitherto observed by chemists. Various observations have been made to enable physicians to distinguish pus from the mucus of the internal cavities, especially of the lungs. In cases of copious expectoration, it is sometimes of consequence to know whether the matter thrown out of the lungs is pus or mucus. Mr. Charles Darwin made a set of experiments on the subject, and pointed out three criteria to distinguish pus: 1. Sulphuric acid dissolves it. When the solution is diluted, the pus precipitates; but mucus treated in the same manner swims. But this distinction depends upon the quantity of water added, and is therefore ambiguous. 2. Pus is diffusible through diluted sulphuric acid, through water, and through brine; but mucus is not. 3. Alkaline leys dissolve pus; water precipitates pus thus dissolved, but not mucus. How far these two last distinctions prevail is rather doubtful. Grasmeyer has proposed the following method, which he considers as complete: Triturate the substance to be tried, with an equal quantity of warm water; then add to it an equal portion of a saturated solution of carbonat of potass, and set the mixture aside. If it contains pus, a transparent jelly subsides in a few hours; but this does not happen if only mucus is present.

2. When the ulcer is ill-continued, the pus secreted in it possesses different properties. It has usually a fetid smell, is much thinner, and to a certain degree acrid. We are in possession of two sets of experiments on this unhealthy pus: one by Mr. Cruickshank on the pus discharged from what is called the hospital sore; another by Dr. Crawford on the matter of cancers.

The pus from the hospital sore possesses most of the properties of healthy pus; but is distinguished by its odour, and by some shades of difference when exposed to the action of the metallic precipitates. Limewater changes its fetid odour, but does not destroy it; sulphuric acid increases it, as do alcohol and the solution of oxide of arsenic in potass. Bark has no effect upon it; but it is destroyed by the nitrat and oxymuriat of mercury, by nitric acid, and by oxymuriatic acid. Nitrat of silver does not destroy it. Mr. Cruickshank supposes that the fetid smell is occasioned by the alteration of some part of true pus. He considers the pus of the hospital sore as a matter sui generis, which is capable of generating more, and even of producing an alteration in the system. Hence to heal the sore the matter must be destroyed, and prevented from appearing again. This was done by washing the sores with nitrat of mercury, diluted nitric acid, and oxymuriatic acid, at every dressing. This method constantly succeeded with Dr. Rollo, except when the sore was too large to admit it to be put in practice completely.

3. The matter of cancer, examined by Dr. Crawford, gave a green colour to syrup of violets. Potass produced no change; but sulphuric acid extricated a gas which possessed many of the properties of sulphureted hydrogen. This gas he supposes to exist in the matter united to ammonia. The presence of this compound explains the effects of the matter of cancer and virulent matter in general upon metallic salts. Dr. Crawford found that the odour of this matter was completely destroyed by oxymuriatic acid; and therefore recommends it as a proper substance for washing cancerous ulcers.

4. Besides the species mentioned above, there are many others which we know from their effects to be peculiar, though we cannot find any chemical distinctions between them sufficiently well marked. But that they are specifically different cannot be doubted, if we consider that every one of them produces a disease peculiar to itself. The matter of small-pox, of venereal ulcers, of cowpox, &c. may be mentioned as instances.

The liquor which fills the cavities of the body in dropsy has a yellowish-green colour, and is sometimes turbid, sometimes nearly transparent. As far as it has been examined, it agrees exactly with the serum of the blood; and the liquid which makes its appearance when the epidermis is raised into blisters, is perfectly transparent and liquid. When the blisters are artificial, it is usually yellow, and has the odour of the blistering-plaster. From the experiments of Margueron, we learn that it is composed of the same constituents as the serum of the blood. From 200 parts of this liquid he obtained

36	albumen
4	muriat of soda
2	carbonat of soda
2	phosphat of lime
156	water
200.	

PUTLOGS, or Putlocks, in building, are short pieces of timber about seven feet long, used in building scaffolds. They lie at right angles to the wall, with one of their ends resting upon it, and the other upon the poles which lie parallel to the side of the wall of the building.

PUTREFACTION. The rapidity with which animal bodies undergo decomposition, and the disgusting fetor which accompanies this decomposition, have long been considered as some of their most striking peculiarities. This spontaneous destruction is denominated putrefaction. Considerable attention has been paid to it by chemists. Becchar and Stahl have described with fidelity the phenomena with which it is attended, and the circumstances necessary for its taking place. To sir John Pringle we are indebted for some important experiments on the method of retarding putrefaction; neither are the experiments of Dr. Macbride less valuable, though the consequences which he drew from them were erroneous. We are indebted also to Crell and Priestley for many valuable facts; and to Berthollet and Lavoisier for the first attempts to determine the real changes which take place, and the manner in which the new products which appear during putrefaction are formed. But notwithstanding the labours of these philosophers, and of many others, much is still wanting to enable us to trace the complicated changes which take place during putrefaction, and to account for them in a satisfactory manner.

It has been ascertained long ago, that putrefaction never takes place in those animal substances which contain only two or three ingredients, such as oils, resins, sugar; they must always be more complicated in their texture; and, perhaps, in all cases, a mixture of two or more compound bodies is necessary for speedy decomposition. But however complicated the animal substance may be, it does not putrefy unless moisture is present; for dry animal substances are not susceptible of alteration. A certain degree of heat is also necessary. Animal bodies may be kept without decomposing for any length of time at the freezing temperature. In general the higher the temperature, the more rapid is the putrefaction, provided the heat is not great enough to reduce the animal body to dryness. It has been observed, too, that putrefaction advances with more rapidity in the open air; but exposure to the air is not necessary, though it modifies the decomposition.

When these conditions are observed, and dead animal matter is left to itself, its colour becomes gradually paler, and its consistence diminishes; if it is a solid part, such as flesh, it softens, and a serous matter sweats out, the colour of which quickly changes; the texture of the part becomes relaxed, and its organization destroyed; it acquires a disagreeable smell; the substance gradually sinks down, and is diminished in bulk; its smell becomes stronger and ammoniacal. If the subject is contained in a close vessel, the progress of putrefaction, at this stage, seems to slacken; no other smell but that of a pungent alkali is perceived; the matter effervesces with acids, and converts syrup of violets to a green. But if the communication with the air is admitted, the urinous exhalation is dissipated, and a peculiar putrid smell is spread around with a kind of impetuosity; a smell of the most insupportable kind, which lasts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids; this smell is corrected, and in a manner confined, by ammonia. When the latter is volatilized, the putrefactive process becomes active a second time, and the substance suddenly swells up, becomes filled with bubbles of air, and soon after subsides again. Its colour changes, the fibrous texture of the flesh being then scarcely distinguishable; and the whole is changed into a soft brown, or greenish matter, of the consistence of a poultice, whose smell is faint, nauseous, and very active on the bodies of animals. The odorant principle gradually loses its force; the fluid portion of the flesh assumes a kind of consistence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliquescent; which being rubbed between the fingers, breaks into a coarse powder like earth. This is the last state observed in the putrefaction of animal substances; they do not arrive at this term but at the end of a considerable time.

During this decomposition, a variety of gaseous bodies are emitted; these vary according to the substance exposed to putrefaction; but they consist chiefly of hydrogen gas, holding sulphur, phosphorus, and carbon, in solution; of ammonia, water, and carbonic acid, and perhaps also of azotic gas. Nitric acid seems in some cases to be formed and emitted. The earthy-like residuum, which remains after the decomposition is completed, consists of the fixed parts of the animal substance, mixed with charcoal, oil, and ammonia. Thus it appears that putrefaction consists in a total decomposition of the animal body; the elements of which combine together two and two, and thus form a new set of less complicated bodies. But any attempt to explain the manner in which these changes take place would be exceedingly imperfect indeed; not only because we are ignorant of the strength of the affinities of the different elementary parts of animal bodies for each other, but because we do not even know the manner in which these elements are combined, and consequently we cannot know by what particular forces these compounds are destroyed.

In carcases buried in the earth, putrefaction takes place much more slowly; but it is scarcely possible to observe its progress with accuracy. The abdomen is gradually dilated with elastic fluids which make their appearance in it, and at last it bursts and discharges a horribly fetid and noxious gas; at the same time a dark-coloured liquid flows out. If the earth is very dry, and the heat considerable, the moisture is often absorbed so rapidly, that the carcase, instead of putrefying, dries, and is transformed into what is called a mummy.

Such are the phenomena when dead bodies are left to putrefy separately; but when great numbers of carcases are crowded together in one place, and are so abundant as to exclude the action of external air and other foreign agents, their decomposition is entirely the consequence of the reciprocal action of their ingredients themselves upon each other, and the result is very different. The body is not entirely dissipated or reduced to mould, but all the soft parts are found diminished remarkably in size, and converted into a peculiar saponaceous matter. This singular change was first accurately observed in the year 1786.

The burial-ground of the Innocents in Paris having become noxious to those who lived in its neighbourhood, on account of the disagreeable and hurtful odour which it exhaled, it was found necessary to remove the carcases to another place. It had been usual to dig very large pits in the burial-ground, and to fill them with the carcases of the poorer sort of people, each in its proper bier; and when they were quite full, to cover them with about a foot deep of earth, and to dig another similar pit, and fill it in the same manner. Each pit held between one thousand and fifteen hundred bodies. It was in removing the bodies from these pits that this saponaceous substance was found. The grave-diggers had ascertained by long experience, that about thirty years were required before all bodies had undergone this change in its full extent. Every part of the body acquired the properties of this substance. The intestines and viscera of the thorax had completely disappeared; but what is singular enough, the brain had lost but little of its size or appearance, though it was also converted into the same substance.

This sponaceous matter was of a white colour, soft and unctuous to the touch, and melted, when heated, like tallow. It exhibited all the properties of a soap, containing, however, an excess of fatty matter. Fourcroy, who analysed it, found that it was composed of a fatty matter combined with ammonia, and that it contained also some phosphat of lime and ammonia. Diluted acids decomposed it, and separated the fatty matter; alkalies and lime, on the other hand, drove off the ammonia. When exposed to the air, it gradually lost its white colour; the ammonia, in a great measure, evaporated; and what remained had something of the appearance of wax. It absorbed water with great avidity, and did not part with it readily. Its white colour was owing to the presence of that liquid. The oily matter, when separated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyish-brown colour, with a lamellar and crystalline texture, like that of spermaceti; but if it has been rapidly dried, it assumes the appearance of wax. It melts when heated to 126°; when properly purified, by passing it through a linen cloth while fluid, it has scarcely any smell. Alcohol does not act upon it while cold, but at the temperature of 120° it dissolves it: when the solution cools, the fatty matter precipitates, and forms a gritty mass. With alkalies it forms a soap; and when set on fire it burns precisely like oil or fat, only that it exhales a more unpleasant odour.

Mr. Smith Gibbes found the same substance in the pit into which animal matters are thrown at Oxford after dissection. A small stream of water constantly passes through this pit; a circumstance which induced him to try whether animal muscle exposed to the action of a running stream underwent the same change. The experiment succeeded completely: he attempted, in consequence, to render this substance, to which he gave the name of spermaceti, useful in those manufactures which require tallow; but the fetid odour which it constantly exhales was an insurmountable objection. Attempts were indeed made to get over it; and a manufacture of Mr. Smith Gibbes's spermaceti was even established at Bristol.

Many attempts have been made to retard the destructive progress of putrefaction, in order to preserve animal bodies either as food or for other useful purposes; and several methods have been ascertained which prevent it from operating for a considerable time.

1. The freezing temperature is a complete preservation from putrefaction, as long as the animal substance is exposed to it. Hence the common practice of keeping meat in snow in the frozen climates of the north; and of packing fish in ice, and sending them in that state from Scotland to the London market.

2. Almost all bodies which have a strong affinity for water retard putrefaction for a longer or shorter time, doubtless by depriving the animal substances of their water, or preventing that liquid from acting upon these bodies in its usual manner. In this way the acids, sugar, alcohol, &c. seem to prevent or retard putrefaction.

3. It is well known that common salt is a powerful antiseptic. Hence the practice of salting meat, and the length of time which meat that has undergone this operation may be kept. Several other salts, especially nitre, possess the same property. In what manner these bodies act has not been ascertained; but they undoubtedly produce some chemical change upon the meat; for they alter its taste, its colour, and other sensible properties.

4. Many aromatics, such as camphor, resins, volatile oils, bitumens, and other similar bodies, act with considerable efficacy in preserving animal bodies from putrefaction. Hence their utility in embalming. In what the action of these substances consists has not been ascertained. Part of their efficacy is doubtless owing to the rapidity with which the animal substances to which they are applied lose their moisture; and something may be ascribed likewise to their odour, which keeps insects at a distance, and thus prevents the lodging of excrementitious matter, which always acts powerfully as a putrefactive ferment.

PUTI *caraja*, in botany, is a genus of Indian plants, of which the characters, as given by sir William Jones in the Asiatic Researches, vol. ii. p. 351. are these: The calyx is five-cleft; the corolla has five equal petals; the pericarpium a thorny legumen and two seeds, the leaves oval and pinnated, and the stem armed. "The seeds (says the learned president) are very bitter, and perhaps tonic; since one of them, bruised and given in two doses, will cure the intermittent fever."

PUTTY, in the arts. When tin is melted in an open vessel, its surface soon becomes covered with a grey powder, which is an oxide of the metal. If the heat is continued, the colour of the powder gradually changes, and at last becomes yellow. In this state it is known by the name of putty, and employed in polishing glass and other hard substances.

Putty is also a kind of paste compounded of whiting and linseed-oil, beaten together to the consistence of a thick dough. It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PUZZULANA or Pozzolana, *terra*, or *terras*, is a greyish kind of earth used in Italy for building under water. The best is found about Puteoli, Baiæ, and Cumæ, in the kingdom of Naples, from the first of which places it derives its name. It is supposed to be a volcanic product, composed of heterogeneous substances, thrown out from the burning mouths of volcanoes in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance. This volcanic earth is of a grey, brown, or blackish colour; of a loose, granular, or dusty and rough, porous, or spongy, texture, resembling a clay hardened by fire, and then reduced to a gross powder. It contains various heterogeneous substances mixed with it. Its specific gravity is from 2500 to 2800; and it is, in some degree, magnetic: it scarcely effervesces with acids, though partially soluble in them. It easily melts per se; but its most distinguishing property is, that it hardens very suddenly when mixed with one-third of its weight of lime and water, and forms a cement which is more durable in water than any other.

According to Bergman's analysis, 100 parts of it contain from 55 to 60 of silica, 20 of alumina, five or six of lime, and from 15 to 20 of iron. Its effects, however, in cement, may perhaps depend only on the iron which has been reduced into a particular substance by means of subterraneous fires; evident signs of which are observable in the places where it is obtained. If the slate in Henneberg or Kennekulle, in the province of Westergottland, should happen to get fire, the uppermost stratum, which now consists of a mixture of iron and different kinds of rocks, called graberg in the account given of them, might perhaps be changed partly into slag and partly into terra puzzolana.

It is evidently a martial argillaceous marl, that has suffered a moderate heat. Its hardening power arises from the dry state of the half-baked argillaceous particles, which makes them imbibe the water very rapidly, and thus accelerates the desiccation of the calcareous part. It is found not only in Italy but in France, and the provinces of Auvergne and Limoges; and also in England and elsewhere.

PYLORUS. See ANATOMY.

PYRAMID, in geometry, a solid standing on a triangular, square, or polygonal basis, and terminating in a point at the top; or according to Euclid, it is a solid figure, consisting of several triangles, whose bases are all in the same plane, and which have one common vertex.

Hence the superficies of a given pyramid is easily found by measuring these triangles separately; for their sum added to the area of the base, is the surface of the pyramid required.

It is no less easy to find the solid content of a given pyramid; for the area of the base being found, let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, and the product will give the solid content, as is demonstrated by Euclid, lib. 12. prop. 7.

If the solid content of a frustum of a pyramid is required, first let the solid content of the whole pyramid be found; from which subtract the solid content of the part that is wanting, and the solid content of the frustum or broken pyramid will remain.

Every pyramid is equal to one-third of its subscribing prism, or one that has the same base and height. All pyramids are in a ratio compounded of their bases and altitudes; so that, if their bases are equal, they are in proportion to their altitudes; and vice versa.

Equal pyramids reciprocate their bases and altitudes; that is, the altitude of one is to that of the other, as the base of the one is to that of the other.

PYRAMID, in architecture, a solid massive building, which from a square, triangular, or other base, rises diminishing to a vertex or point.

Pyramids are sometimes used to preserve the memory of singular events; and sometimes to transmit to posterity the glory and magnificence of princes. But as they are esteemed a symbol of immortality, they are most commonly used as funeral monuments. Such are that of Cestius of Rome; and those very celebrated pyramids of Egypt, as famous for the enormity of their size as their antiquity. These are situated on the west side of the Nile, almost opposite to Grand Cairo; the base of the largest covers more than ten acres of ground; and it is, according to some, near seven hundred feet high, though others make it six hundred, and some but little more than five hundred. The pyramid is said to have been, among the Egyptians, a symbol of human life; the beginning of which is represented by the base, and the end by the apex; on which account it was, that they used to erect them over sepulchres.

PYRAMIDALIA CORPORA. See ANATOMY.

PYRITES, a genus of inflammable substances, composed of sulphur, which has dissolved or saturated itself with metals. Thus there are many kinds of pyrites; as of gold, arsenic, iron, &c. It is also the principal ore of sulphur; particularly that called martial pyrites, copperas-stone, or marcasite. This is very common, containing a quantity of sulphur in proportion to the iron; and, when thoroughly inflamed, burns by itself. It is either of a compact texture, steel-grained, coarse-grained, or crystallised. In this last form, it shoots mostly into cube and octahedral figures, though it is met with also in innumerable other forms. The liver-coloured marcasite has an appearance between that of the preceding and the blue copper-ore. The iron predominates in this kind, so that it is less fit than the other for extracting sulphur for it, or for the smelting of copper ores. It is formed of a compact texture, coarse-grained, and steel-grained. See SULPHURETS, IRON, &c.

PYROLA, *winter-green*, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is quinquepartite; there are five petals; the capsule is quinquelocular, opening at the angles. There are six species, natives of Britain.

PYROMETER, an instrument for measuring the expansion of bodies by heat. Muschenbroeck, who was the original inventor of this machine, has given a table of the expansion of the different metals in the same degree of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at thirty-two degrees. The effects of this experiment are digested in the following table, where the degrees of expansion are marked in parts equal to 1-12500th part of an inch.

Expansion of	*Iron*	*Steel*	*Copp.*	*Brass*	*Tin*	*Lead*
By 1 flame.	80	85	89	110	153	155
By 2 flames placed close together.	117	123	115	220		274
By 2 flames $2\frac{1}{2}$ inches distant.	109	94	92	141	219	263
By 3 flames placed close together.	142	168	193	275		
By 4 flames placed close together.	211	270	273	361		
By 5 flames.	230	310	310	377		

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments, it appears at first view that iron is the least rarefied of any of these metals, whether it is heated by one or more flames; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same in summer and in winter. The expansion of lead and that of tin are nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames placed together, cause a greater rarefaction than when they have a sensible interval between them; iron in the former case being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious.

By comparing the expansions of the same metal produced by one, two, three, or more flames, it appears that two flames do not cause double the expansion of one, nor three flames three times that expansion, but always less; and these expansions differ so much the more from the ratio of the number of flames, as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more and some less. Thus tin began to run when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

Mr. Ellicot found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow:

Gold,	Silver,	Brass,	Copper,	Iron,	Steel,
73	103	95	89	60	56
Lead					
149					

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat.

Mr. Graham used to measure the minute

alteration in length of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four-thousandth part of an inch. On this general principle Mr. Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw.

The following table shews how much a foot in length of each metal grows longer by an increase of heat corresponding to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expressed in parts of which the unit is equal to the 10,000th part of an inch.

1. White glass barometer-tube, -	100
2. Martial regulus of antimony, -	130
3. Blistered steel, - - -	138
4. Hard steel, - - - -	147
5. Iron, - - - - -	151
6. Bismuth, - - - -	167
7. Copper hammered, - -	204
8. Copper eight parts, with tin one	218
9. Cast brass, - - - -	225
10. Brass sixteen parts, with tin one,	229
11. Brass-wire, - - - -	232

20. Zinc hammered half an inch per foot, - - - - - -	373

PYROPS, a mineral found in Bohemia, which was formerly distinguished by the name of Bohemian garnet. It is never found crystallized, but only in round or angular fragments, usually small. Colour deep red, which passes to orange when the mineral is exposed to the sun. It is very hard; the specific gravity is from 3.7 to 3.9. Fracture conchoidal and very brilliant. It is composed of

40.00	silica
28.50	alumina
10.00	magnesia
3.50	lime
16.50	oxide of iron
0.25	oxide of manganese.
98.75	

PYROPHORUS, a substance which has the property of catching fire whenever it is exposed to the open air. See SULPHATS.

PYROSTRIA, a genus of the tetrandria monogynia class and order. The cal. is four-toothed; cor. bell-shaped; nuts eight, one-seeded. There is one species, a small tree of Mauritius.

PYROTECHNY, the art of fire, or a science which teaches the management and application of fire in several operations. But the term is more particularly used to denote the doctrine of artificial fireworks.

Of ingredients and compositions.

1. Saltpetre is the principal ingredient in fire-works; but will not answer so well when foul and gross as when purified from its crude and earthy parts, which greatly retard its velocity; when, therefore, any quantity of fire-works are to be made, it should be examined; for if it is not well cleansed, and of a good sort, your works will not have their proper effect; neither will it agree with the standing proportions of compositions.

To refine it, put into a copper, or any other vessel, 100 lb. of rough nitre with 14 gallons of clean water; let it boil gently half an hour, and as it boils take off the scum; then stir it, and before it settles put it into your filtring-bags, which must be hung on a rack, with glazed earthen pans under them, in which must be sticks laid across for the crystals to adhere to: it must stand in the pans two or three days to shoot; then take out the crystals, and let them dry. The water that remains in the pans boil again an hour, and strain it into the pans as before, and the saltpetre will be quite clear and transparent; if not, it wants more refining; to do which proceed as usual, till it is well cleansed of all its earthy parts.

N. B. Those who do not chuse to procure their saltpetre by the above method, may buy it ready-done, which for fire-works in general will answer.

To pulverise saltpetre. Take a copper kettle, whose bottom must be spherical, and put into it 14 lb. of refined saltpetre, with 2 quarts or five pints of clean water: then put the kettle on a slow fire, and when the saltpetre is dissolved, if any impurities arise, skim them off, and keep constantly stirring it with two large spatulas, till all the water exhales; and when done enough, it will appear like white sand, as fine as flour; but if it should boil too fast, take the kettle off the fire, and set it on some wet sand, which will prevent the nitre from sticking to the kettle. When you have pulverised a quantity of saltpetre, be careful to keep it in a dry place.

2. Sulphur is one of the principal ingredients in gunpowder, and almost in all compositions of fire-works; and therefore great care must be taken of its being good, and brought to the highest perfection. To know when sulphur is good, you are to observe that it is of a high yellow; and if, when held in one's hand, it crackles and bounces, it is a sign that it is fresh and good: but as the method of reducing brimstone to a powder is very troublesome, it is better to buy the flour ready-made, which is done in large quantities, and in great perfection; though when a grand collection of fire-works is to be made, the strongest and best sulphur is the lump-brimstone well ground.

3. Charcoal for fire-works must always be soft and well burnt, which may be bought ready-done.

4. See GUNPOWDER in the order of the alphabet. It is mealed or ground in mortars, &c.

5. Camphor may be had in the shops; and is of two kinds, differing in regard to the degree of their purity, and distinguished by the name of rough and refined. Refined camphor must be chosen of a perfectly clean white colour, very bright and pellucid, of the same smell and taste with the rough, but more acrid and pungent.

6. Benjamin is one of the ingredients in odoriferous fire-works, when reduced to a fine flour; which may be done by putting into a deep and narrow earthen pot between three and four ounces of benjamin grossly pounded; cover the pot with paper, which tie very closely round the edge; then set the pot on a slow fire, and once in an hour take off the paper, and you will find some flour sticking to it, which return again in the pot; this you must continue till the flour appears white and fine. There is also an oil of benjamin, which is sometimes drawn from the dregs of the flour; it affords a very good scent, and may be used in wet compositions.

7. Spur-fire. As the beauty of this composition cannot be seen at so great a distance as brilliant fire, it has a better effect in a room than in the open air, and may be fired in a chamber without any danger: it is of so innocent a nature, that, though with an improper phrase, it may be called a cold fire; and so extraordinary is the fire produced from this composition, that, if well made, the sparks will not burn a handkerchief when held in the midst of them; you may hold them in your hand while burning, with as much safety as a candle; and if you put your hand within a foot of the mouth of the case, you will feel the sparks like drops of rain. When any of these spur-fires are fired singly, they are called artificial flower-pots; but some of them placed round a transparent pyramid of paper, and fired in a large room, make a very pretty appearance.

The composition consists of saltpetre 4 lb. 8 oz., sulphur 2 lb. and lamp-black 1 lb. 8 oz.; or, saltpetre, 1 lb., sulphur $\frac{1}{2}$ lb. and lamp-black quarts. This composition is very difficult to mix. The saltpetre and brimstone must be first sifted together, and then put into a marble mortar, and the lamp-black with them, with you work down by degrees with a wooden pestle, till all the ingredients appear of one colour, which will be something greyish, but very near black: then drive a little into a case for trial, and fire it in a dark place; and if the sparks, which are called stars, or pinks, come out in clusters, and afterwards spread well without any other sparks, it is a sign of its being good, otherwise not; for if any drossy sparks appear, and the stars not full, it is then not mixed enough; but if the pinks are very small, and soon break, it is a sign that you have rubbed it too much. The reason of its being called spur-fire, is because the sparks it yields have a great resemblance to the rowel of a spur.

8. To prepare cast iron for gerbes, white fountains, and Chinese fire. Cast iron being of so hard a nature as not to be cut by a file, we are obliged to reduce it into grains, though somewhat difficult to perform; but if we consider what beautiful sparks this sort of iron yields, no pains should be spared to granulate such an essential material: to do which, get at an iron-foundry some thin pieces of iron, such as generally run over the mould at the time of casting: then have a square block made of cast iron, and an iron square hammer about four pounds weight; then, having covered the floor with cloth or something to catch the beatings, lay the thin pieces of iron on the block, and beat them with the hammer till reduced into small grains; which afterwards searce with a very fine sieve, to separate the fine dust, which is sometimes used in small cases of brilliant fire instead of steel-dust; and when you have got

out all the dust, sift what remains with a sieve a little larger, and so on with sieves of different sizes, till the iron passes through about the bigness of small bird-shot: your iron thus beaten and sifted, put each sort into wooden boxes or oiled paper, to keep it from rusting. When you use it, observe the difference of its size, in proportion to the cases for which the charge is intended; for the coarse sort is only designed for very large gerbes of 6 or 8lb.

9. Charges for sky-rockets, &c. Rockets of four ounces. Mealed powder one lb. four oz. saltpetre four oz. and charcoal two oz. Rockets of eight ounces. I. Mealed powder one lb. saltpetre four oz. brimstone three oz. and charcoal one and a half oz. II. Meal-powder one and a half lb. and charcoal four and a half oz. Rockets of one pound. Meal-powder two lb. saltpetre eight oz. brimstone four oz. charcoal two oz. and steel filings one and a half oz. Sky-rockets in general. I. Saltpetre four lb. brimstone one lb. and charcoal one and a half lb. II. Saltpetre four lb. brimstone one and a half lb. charcoal one lb. twelve oz. and meal-powder two oz. Large sky-rockets. Saltpetre four lb. meal-powder one lb. and brimstone one lb. Rockets of a middling size. I. Saltpetre eight lb. sulphur three lb. meal-powder three lb. II. Saltpetre three lb. sulphur two lb. meal-powder one lb. charcoal one lb.

10. For rocket-stars. White stars. Meal-powder four oz. saltpetre twelve oz. sulphur vivum six oz. oil of spike two oz. and camphor five oz. Blue stars. Meal-powder eight oz. saltpetre four, sulphur two, spirit of wine two, and oil of spike two. Coloured or variegated stars. Meal-powder eight drams, rochpetre four oz. sulphur vivum two, and camphor two. Brilliant stars. Saltpetre three and a half oz. sulphur one and a half, and meal-powder three-fourths, worked up with spirits of wine only. Common stars. Saltpetre one lb. brimstone four oz. antimony four and three-fourths, isinglass a half, camphor a half, and spirit of wine three-fourths. Tailed stars. Meal-powder three oz. brimstone two, saltpetre one, and charcoal (coarsely ground) three-fourths. Drove stars. I. Saltpetre three lb. sulphur one lb. brass-dust twelve oz. antimony three. II. Saltpetre one lb. antimony four oz. and sulphur eight. Fixed pointed stars. Saltpetre eight and a half oz. sulphur two, antimony one oz. ten dr. Stars of a fine colour. Sulphur one oz. meal-powder one, saltpetre one, camphor four dr. oil of turpentine four dr.

11. Rains. Gold rain for sky-rockets. I. Saltpetre one lb. meal-powder four oz. sulphur four, brass-dust one, saw-dust two and a quarter, and glass-dust six dr. II. Meal-powder twelve oz. saltpetre two, charcoal four. III. Saltpetre eight oz. brimstone two, glass-dust one, antimony three-fourths, brass-dust one-quarter, and saw-dust 12 dr. Silver rain. I. Saltpetre four oz. sulphur, meal-powder, and antimony, of each two oz. sal prunella one half oz. II. Saltpetre one half lb. brimstone two oz. and charcoal four. III. Saltpetre one lb. brimstone one-quarter lb. antimony six oz. IV. Saltpetre four oz. brimstone one, powder two, and steel-dust three-fourth oz.

12. Water-rockets. I. Meal-powder six lb. saltpetre four, brimstone three, charcoal five. II. Saltpetre one lb. brimstone four and a half oz. charcoal six. III. Saltpetre one lb. brimstone four oz. charcoal twelve. IV. Saltpetre 4 lb. brimstone 1½ lb. charcoal one lb. twelve oz. V. Brimstone two lb. saltpetre four lb. and meal-powder four. VI. Saltpetre one lb. meal-powder four oz. brimstone eight and a half, charcoal two. VII. Meal-powder one lb. saltpetre three, brimstone one; sea-coal one oz. charcoal eight and a half, saw-dust three-fourths, steel-dust one-half, and coarse charcoal one-fourth oz. VIII. Meal-powder one and three-fourths lb. saltpetre three, sulphur one and a half, charcoal twelve oz. saw-dust two. Sinking charge for water rockets. Meal-powder eight oz. charcoal three-fourths oz.

13. Of wheels. Wheel-cases from two ounces to four pounds. I. Meal-powder two lb. saltpetre four oz. iron-filings seven oz. II. Meal-powder 2lb. saltpetre 12 oz. sulphur 4, steel-dust 3. III. Meal-powder four lb. saltpetre one lb. brimstone eight oz. charcoal four and a half. IV. Meal-powder eight oz. saltpetre four, saw-dust one and a half, sea-coal three-fourths. V. Meal-powder one lb. four oz. brimstone four oz. ten dr. saltpetre eight oz. glass-dust two and a half. VI. Meal-powder twelve oz. charcoal one, saw-dust one-half. VII. Saltpetre one lb. nine oz. brimstone four oz. charcoal four and a half. VIII. Meal-powder two lb. saltpetre one, brimstone one-half, and sea-coal two. IX. Saltpetre two lb. brimstone one, meal-powder four, and glass-dust four oz. X. Meal-powder one lb. saltpetre two oz. and steel-dust three and one-half. XI. Meal-powder two lb. and steel-dust two and one-half oz. with two and one-half of the fine dust of beat iron. XII. Saltpetre two lb. thirteen oz. brimstone eight oz. and charcoal. Slow fire for wheels. I. Saltpetre four oz. brimstone two, and meal-powder one and a half. II. Saltpetre four oz. brimstone one, and antimony one oz. six dr. III. Saltpetre four and one-half oz. brimstone one oz. and meal-powder one and a half. Dead fire for wheels. I. Saltpetre one one-fourth oz. brimstone one-fourth, lapis-calaminaris one-fourth, and antimony two dr.

14 Standing or fixed cases. I. Meal-powder four lb. saltpetre two, brimstone and charcoal one. II. Meal-powder two lb. saltpetre one, and steel-dust eight oz. III. Meal-powder one lb. four oz. and charcoal four oz. IV. Meal-powder one lb. and steel-dust four oz. V. Meal-powder two and one-half lb. brimstone four oz. and sea-coal six. VI. Meal-powder three lb. charcoal five oz. and saw-dust one and a half.

15. Sun-cases. I. Meal-powder eight and one-half lb. saltpetre one lb. two oz. steel-dust two lb. ten oz. brimstone four. II. Meal-powder three lb. saltpetre six oz. and steel-dust seven and one-half.

16. A brilliant fire. Meal-powder eleven lb. saltpetre one, brimstone four oz. steel-dust one and a half.

17. Gerbes. Meal-powder six lb. and beat iron two lb. one and a half oz.

18. Chinese fire. Saltpetre twelve oz. meal-powder two lb. brimstone one lb. two oz. and beat iron twelve oz.

19. Tourbillons. Charge for four-ounce tourbillons. Meal-powder two lb. four oz. and charcoal four and one-eighth oz. Eight-ounce tourbillons. Meal-powder two lb. and charcoal four and three-fourths oz. Large tourbillons. Meal-powder two lb. saltpetre one, brimstone eight oz. and beat-iron eight. Tourbillons may be made very large, and of different coloured fires: only you have to observe, that the larger they are, the weaker must be the charge; and, on the contrary, the smaller, the stronger their charge.

20. Water balloons. I. Saltpetre four lb. brimstone two, meal-powder two, antimony four oz. saw-dust four, glass-dust one and one-half. II. Saltpetre nine lb. brimstone three lb. meal-powder six lb. rosin twelve oz. and antimony eight oz.

21. Water squibs. I. Meal-powder one lb. and charcoal one lb. II. Meal-powder one lb. and charcoal nine oz.

22. Mine ports or serpents. I. Meal-powder one lb. and charcoal one oz. II. Meal-powder nine oz. charcoal one oz.

23. *Port-fires.* For firing rockets, &c. I. Saltpetre twelve oz. brimstone four oz and meal-powder two oz. II. Saltpetre eight oz. brimstone four oz. and meal-powder two oz. III. Saltpetre one lb. meal-powder one and one-half and brimstone ten oz. This composition must be moistened with one gill of linseed oil. IV. Meal-powder six oz. saltpetre two lb. two oz. and brimstone ten oz. V. Saltpetre one lb. four oz meal-powder four oz. brimstone five oz. saw-dust eight oz. VI. Saltpetre eight oz. brimstone two oz. and meal-powder two oz. For illuminations. Saltpetre one lb. brimstone eight oz. and meal-powder six oz.

24. *Cones or spiral wheels.* Saltpetre one and one-half lb. brimstone six oz. meal-powder fourteen oz. and glass-dust fourteen oz.

25. *Crowns or globes.* Saltpetre six oz. brimstone two lb. antimony four oz. and camphor two oz.

26. *Air-balloon fuzes.* I. Saltpetre one lb. ten oz. brimstone eight oz. and meal-powder one lb. six oz. II. Saltpetre one and one-half, brimstone eight oz. and meal-powder one lb. eight oz.

27. *Serpents for pots des brins.* Meal-powder one lb. eight oz. saltpetre twelve oz. and charcoal two oz.

28. *Fire pumps.* I. Saltpetre five lb. brimstone one lb. meal-powder one and one-half lb. and glass-dust one lb. II. Saltpetre five lb. eight oz. brimstone two lb. meal-powder one lb. eight oz. and glass-dust one lb. eight oz.

29. *A slow white flame.* I. Saltpetre two lb. brimstone three lb. antimony one lb. II. Saltpetre three and one-half lb. sulphur two and one-half lb. meal-powder one lb. antimony one lb. glass-dust four oz. brass-dust one oz. N. B. These compositions, driven one-fourth inch in a one-oz. case, will burn one minute; which is much longer time than an equal quantity of any composition yet known will last.

30. *Amber lights.* Meal-powder nine oz. amber three oz. This charge may be drove in small cases, for illuminations.

31. *Lights of another kind.* Saltpetre three lb. brimstone one lb. meal powder one lb. antimony ten and one-half oz. All these must be mixed with the oil of spike.

32. *A red fire.* Meal-powder three lb. charcoal twelve oz. and saw-dust eight oz.

33. *A common fire.* Saltpetre three lb. charcoal ten oz. and brimstone two oz.

34. *To make an artificial earthquake.* Mix the following ingredients to a paste with water, and then bury it in the ground, and in a few hours the earth will break and open in several places. The composition: sulphur 4lb. and steel-dust 4lb.

35. *Compositions for stars of different colours.* 1. Meal-powder 4 oz. saltpetre 2 oz. brimstone 2 oz. steel-dust $1\frac{1}{2}$ oz. and camphor, white amber, antimony, and mercury sublimate, of each half an ounce. 2. Rochepetre 10 oz. brimstone, charcoal, antimony, meal-powder, and camphor, of each $\frac{3}{4}$ oz. moistened with oil of turpentine. These compositions are made into stars, by working into a paste, with aqua vitæ, in which has been dissolved some gum tragacanth; after you have rolled them in powder, make a hole through the middle of each, and string them on quick-match, leaving two inches between each. 3. Saltpetre 8 oz. brimstone 2 oz. yellow amber 1 oz. antimony 1 oz. and powder 3 oz. 4. Brimstone $2\frac{1}{2}$ oz. saltpetre 6 oz. olibanum or frankincense in drops 4 oz.; mastic, and mercury sublimate, of each 4 oz. meal-powder 5 oz. white amber, yellow amber, and camphor, of each 1 oz. antimony and orpiment $\frac{1}{2}$ oz. each. 5. Saltpetre 1 lb. brimstone $\frac{1}{2}$ lb. and meal-powder 8 oz. moistened with petrolio-oil. 6. Powder $\frac{1}{2}$ lb. brimstone and saltpetre of each 4 oz. 7. Saltpetre 4 oz. brimstone 2 oz. and meal-powder 1 oz.

Stars that carry tails of sparks. 1. Brimstone 6 oz. antimony crude 2 oz. saltpetre 4 oz. and rosin 4 oz. 2. Saltpetre, rosin, and charcoal, of each 2 oz. brimstone 1 oz. and pitch 1 oz. These compositions are sometimes melted in an earthen pan, and mixed with chopped cotton match, before they are rolled into stars; but will do as well if wetted, and worked up in the usual manner.

Stars that yield some sparks. 1. Camphor 2 oz. saltpetre 1 oz. meal-powder 1 oz. 2. Saltpetre 1 oz. ditto melted $\frac{1}{4}$ oz. and camphor 2 oz. When you would make stars of either of these compositions, you must wet them with gum water, or spirit of wine, in which has been dissolved some gum arabic, or gum tragacanth, that the whole may have the consistence of a pretty thick liquid; having thus done, take 1 oz. of lint, and stir it about in the composition till it becomes dry enough to roll into stars.

Stars of a yellowish colour. Take 4 oz. of gum tragacanth or gum arabic, pounded and sifted through a fine sieve, camphor dissolved in brandy 2 oz. saltpetre 1 lb. sulphur $\frac{1}{2}$ lb. coarse powder of glass 4 oz. white amber $1\frac{1}{2}$ oz. orpiment 2 oz. Being well incorporated, make them into stars after the common method.

Stars of another kind. Take 1 lb. of camphor, and melt it in a pint of spirit of wine over a slow fire; then add to it 1 lb. of gum arabic that has been dissolved; with this liquor mix 1 lb. of saltpetre, 6 oz. of sulphur, and 5 oz. meal-powder; and after you have stirred them well together, roll them into stars proportionable to the rockets for which you intend them.

36. *Colours produced by the different compositions.* As variety of fires adds greatly to a collection of works, it is necessary that every artist should know the different effect of each ingredient. For this reason we shall here explain the colours they produce of themselves, and likewise how to make them retain the same when mixed with other bodies. As, for example, sulphur gives a blue, camphor a white or pale colour, saltpetre a clear white yellow, amber a colour inclining to yellow, sal ammoniac a green, antimony a reddish, rosin a copper-colour, and Greek pitch a kind of bronze, or between red and yellow. All these ingredients are such as show themselves in a flame, viz.

White flame. Saltpetre, sulphur, meal-powder, and camphor: the saltpetre must be the chief part.

Blue flame. Meal-powder, saltpetre, and sulphur vivum; sulphur must be the chief: or meal-powder, saltpetre, brimstone, spirit of wine, and oil of spike; but let the powder be the principal part.

Flame inclining to red. Saltpetre, sulphur, antimony, and Greek pitch: saltpetre the chief.

By the above method may be made various colours of fire, as the practitioner pleases; for, by making a few trials, he may cause any ingredient to be predominant in colour.

37. *Ingredients that show in sparks when rammed in choaked cases.* The set colours of fire produced by sparks are divided into four sorts, viz. the black, white, grey, and red. The black charges are composed of two ingredients, which are meal-powder and charcoal: the white of three, viz. saltpetre, sulphur, and charcoal: the grey of four, viz. meal-powder, saltpetre, brimstone, and charcoal; and the red of three, viz. meal-powder, charcoal, and saw-dust.

38. *Cotton quick-match,* is generally made of such cotton as is put in candles, of several sizes, from one to six threads thick, according to the pipe it is designed for; which pipe must be large enough for the match, when made, to be pushed in easily without breaking it.

The ingredients for the match are, cotton 1 lb. 12 oz. saltpetre 1 lb. spirit of wine 2 quarts, water 3 quarts, isinglass 3 gills, and meal-powder 10lb. To dissolve 4 oz. of isinglass, take 3 pints of water.

39. *Touch-paper for capping of serpents, crackers, &c.* Dissolve in spirit of wine or vinegar, a little saltpetre; then take some purple or blue paper, and wet it with this liquor, and when dry it will be fit for use. When you paste this paper on any of your works, take care that the paste does not touch that part which is to burn.

Of moulds, cases, mixture, instruments, &c.

40. *Rocket-moulds.* As the performance of rockets depends much on their moulds, it is requisite to give a definition of them, and their proportions. They are made and proportioned by the diameter of their orifice, which is divided into equal parts.

Rammers must have a collar of brass at the bottom, to keep the wood from spreading or splitting, and the same proportion must be given to all moulds, from 1 oz. to 6 lb. As to the handles of the rammers, if their diameter is equal to the bore of the mould, and two diameters long, it will be a very good proportion; but the shorter you can use them the better; for the longer the drift, the less will be the pressure on the composition by the blow given with the mallet.

41. *Moulds for wheel-cases or serpents.* This sort of moulds are made of any length or diameter, according as the cases are required; but the diameter of the rollers must be equal to half the bore, and the rammers made quite solid.

42. *To roll rocket and other cases.* Sky-rocket cases are to be made $6\frac{3}{4}$ of their exterior diameter long; and all other cases that are to be filled in moulds must be as long as the moulds, within half its interior diameter. Rocket-cases, from the smallest to 4 or 6 lb. are generally made of the strongest sort of cartridge-paper, and rolled dry; but the large sort are made of pasted pasteboard. As it is very difficult to roll the ends of the cases quite even, the best way will be to keep a pattern of the paper for the different sorts of cases, which pattern should be somewhat longer than the case it is designed for, and on it marked the number of sheets required, which will prevent any paper being cut to waste. Having cut your papers of a proper size, and the last sheet for each case with a slope at one end, so that when the cases are rolled it may form a spiral line round the outside, and that this slope may always be the same, let the pattern be so cut for a guide. Before you begin to roll, fold down one end of the first sheet, so far that the fold will go two or three times round the former; then, on the double edge, lay the former with its handle off the table; and when you have rolled on the paper within two or three turns, lay the next sheet on that part which is loose, and roll it all on. Having thus done, you must have a smooth board, about 20 inches long, and equal in breadth to the length of the case. In the middle of this board must be a handle placed lengthwise. Under this board lay your case, and let one end of the board lie on the table; then press hard on it, and push it forwards, which will roll the paper very tight: do this three or four times before you roll on any more paper. This must be repeated every other sheet of paper, till the case is thick enough; but if the rolling-board is drawn backwards, it will loosen the paper: you are to observe when you roll on the last sheet, that the point of the slope may be placed at the small end of the roller. When the cases are hard to choak, let each sheet of paper (except the first and last, in that part where the neck is formed), be a little moistened with water; immediately after you have struck the concave stroke, bind the neck of the case round with small twine, which must

not be tied in a knot, but fastened with two or three hitches.

Having thus pinched and tied the case so as not to give way, put it into the mould without its foot, and with a mallet drive the former hard on the end piece, which will force the neck close and smooth. This done, cut the case to its proper length, allowing from the neck to the edge of the mouth half a diameter, which is equal to the height of the nipple; then take out the former, and drive the case over the piercer with the long rammer, and the vent will be of a proper size. Wheel-cases must be driven on a nipple with a point to close the neck, and make the vent of the size required; which, in most cases, is generally one-quarter of their interior diameter. As it is very often difficult, when the cases are rolled, to draw the roller out, you may make a hole through the handle, and put in it a small iron pin, by which you may easily turn the former round and pull it out.

Cases are commonly rolled wet, for wheels and fixed pieces; and when they are required to contain a great length of charge, the method of making those cases is thus: your paper must be cut as usual, only the last sheet must not be cut with a slope; having Your paper ready, paste each sheet on one side; then fold down the first sheet as before directed; but be careful that the paste does not touch the upper part of the fold, for if the roller is wetted, it will tear the paper in drawing it out. In pasting the last sheet, observe not to wet the last turn or two in that part where it is to be pinched; for if that part is damp, the pinching-cord will stick to it, and tear the paper; therefore, when you choak those cases, roll a bit of dry paper once round the case before you put on the pinching-cord; but this bit of paper must be taken off after the case is choaked. The rolling-board, and all other methods, according to the former directions for the rolling and pinching of cases, must be used to these as well as all other cases.

43. *To make tourbillon-cases.* This sort of cases are generally made about eight diameters long; but if very large, seven will be sufficient. Tourbillons will answer very well from 4 oz. to 2 lb. but when larger there is no certainty. The cases are best rolled wet with paste, and the last sheet must have a straight edge, so that the case may be all of a thickness. When you have rolled your cases after the manner of wheel-cases, pinch them at one end quite close; then with the rammer drive the ends down flat, and afterwards ram in about one-third of a diameter of dried clay. The diameter of the former for these cases must be the same as for sky-rockets.

44. *Balloon-cases, or paper shells.* First, you must have an oval former turned of smooth wood; then paste a quantity of brown or cartridge paper, and let it lie till the paste has quite soaked through: this done, rub the former with soap or grease, to prevent the paper from sticking to it; then lay the paper on in small slips, till you have made it one-third of the thickness of the shell intended. Having thus done, set it to dry, and when dry, cut it round the middle, and the two halves will easily come off; but observe, when you cut, to leave about one inch not cut, which will make the halves join much better than if quite separated. When you have some ready to join, place the halves even together, paste a slip of paper round the opening to hold them together, and let that dry; then lay on paper all over as before, every where equal, excepting that end which goes downwards in the mortar, which may be a little thicker than the rest; for that part which receives the blow from the powder in the chamber of the mortar consequently requires the greatest strength. When the shell is thoroughly dry, burn a round vent at top, with an iron large enough for the fuze: this method will do for balloons from 4 inches 2-5ths, to 8 inches diameter; but if they are larger, or required to be thrown a great height, let the first shell be turned of elm, instead of being made of paper. For a balloon of 4 inches 2-5ths, let the former be 3 inches 1-8th diameter, and 5¼ inches long. For a balloon of 5½ inches, the diameter of the former must be 4 inches, and 8 inches long. For a balloon of 8 inches, let the diameter of the former be 5 inches and 15-16ths, and 11 inches 7-8ths long. For a 10-inch balloon, let the former be 7 inches 3-16ths diameter, and 14⅘ inches long. The thickness of a shell for a balloon of 4 inches 2-5ths must be half an inch. For a balloon of 5½ inches, let the thickness of the paper be 5-8ths of an inch; for an 8-inch balloon, 7-8ths of an inch; and for a 10-inch balloon, let the shell be 1 inch 1-8th thick. Shells that are designed for stars only, may be made quite round, and the thinner they are at the opening, the better; for if they are too strong, the stars are apt to break at the bursting of the shell. When you are making the shell, make use of a pair of calibres, or a round gage, so that you may not lay the paper thicker in one place than another; and also to know when the shell is of a proper thickness. Balloons must always be made to go easy into the mortars.

Cases for illumination port-fires. These must be made very thin of paper, and rolled on formers from 2 to 5-8ths of an inch diameter, and from 2 to 6 inches long: they are pinched close at one end, and left open at the other. When you fill them, put in but a little composition at a time, and ram it in lightly, so as not to break the case: three or four rounds of paper, with the last round pasted, will be strong enough for these cases.

Cases and moulds for common port-fires. Common port-fires are intended purposely to fire the works, their fire being very slow, and the heat of the flame so intense, that, if applied to rockets, leaders, &c. it will fire them immediately. Port-fires may be made of any length, but are seldom made more than 21 inches long: the interior diameter of port-fire moulds should be 10-16ths of an inch, and the diameter of the former half an inch. The cases must be rolled wet with paste, and one end pinched, or folded down. The moulds should be made of brass, and to take in two pieces lengthwise; when the case is in the two sides, they are held together by brass rings, or hoops, which are made to fit over the outside. The bore of the mould must not be made quite through, so that there will be no occasion for a foot. Those port-fires, when used, are held in copper sockets, fixed on the end of a long stick: these sockets are made like port-crayons, only with a screw instead of a ring.

45. *Of mixing the compositions.* The performance of the principal part of fire-works depends much on the compositions being well mixed; therefore great care must be taken in this part of the work, particularly for the composition for sky-rockets. When you have four or five pounds of ingredients to mix, which is a sufficient quantity at a time, first put the different ingredients together, then work them about with your hands till you think they are pretty well incorporated; after which put them into a lawn sieve with a receiver and top to it; and if, after it is sifted, any remains that will not pass through the sieve, grind it again till fine enough, and if it is twice sifted it will not be amiss; but the compositions for wheels and common works are not so material, nor need be so fine. But in all fixed works, from which the fire is to play regularly, the ingredients must be very fine, and great care taken in mixing them well together; and observe, that in all compositions wherein are steel or iron filings, the hands must not touch: nor will any works which have iron or steel in their charge keep long in damp weather, unless properly prepared, according to the following directions:

46. *To preserve steel or iron filings.* Melt in a glazed earthen pan some brimstone over a slow fire, and when melted throw in some filings, which keep stirring about till they are covered with brimstone: this you must do while it is on the fire; then take it off, and stir it very quick till cold, when you must roll it on a board with a wooden roller till you have broken it as fine as corn-powder; after which sift from it as much of the brimstone as you can. There is another method of preparing filings, so as to keep two or three months in winter: this may be done by rubbing them between the strongest sort of brown paper, which before has been moistened with linseed oil.

47. DIMENSIONS and POISE of ROCKET-STICKS.

To load air-balloons, with the number of stars, serpents, snakes, rain-falls, &c. in shells of each nature.

48. *Mortars to throw aigrettes, &c.* When you fill your shells, you must first put in the serpents, rains, stars, &c. or whatever they are composed of, then the blowing powder; but the shells must not be quite filled. All

those things must be put in at the fuze-hole; but maroons being too large to go in at the fuze-hole, must be put in before the inside shall be joined. When the shells are loaded, glue and drive in the fuzes very tight. For a coehorn balloon, let the diameter of the fuze-hole be $\frac{7}{8}$ths of an inch; for a royal balloon, which is near $5\frac{1}{2}$ inches in diameter, make the fuze-hole 1 inch $\frac{1}{6}$ diameter; for an 8-inch balloon, 1 inch $\frac{2}{8}$ths: and for a 10-inch balloon, 1 inch $\frac{4}{8}$ths.

49. *To make balloon-fuzes.* Fuzes for air-balloons are sometimes turned out of dry beech, with a cup at top to hold the quick-match; but if made with pasted paper, they will do as well. The diameter of the former for fuzes for coehorn balloons must be $\frac{1}{2}$ an inch; for a royal fuze, $\frac{4}{8}$ths of an inch; for an 8-inch fuze, $\frac{3}{4}$ths of an inch; and for a 10-inch fuze, $\frac{7}{8}$ths of an inch. Having rolled your cases, pinch and tie them almost close at one end; then drive them down, and let them dry. Before you begin to fill them, mark on the outside of the case the length of the charge required, allowing for the thickness of the bottom; and when you have rammed in the composition, take two pieces of quick-match about six inches long, and lay one end of each on the charge, and then a little meal-powder, which ram down hard; the loose ends of the match double up into the top of the fuze, and cover it with a paper cap to keep it dry. When you put the shells in the mortars, uncap the fuzes, and pull out the loose ends of the match, and let them hang on the sides of the balloons.

50. *Tourbillons.* Having filled some cases with about $1\frac{1}{2}$ diameter, drive in a ladleful of clay, then pinch their ends close, and drive them down with a mallet. When done, find the centre of gravity of each case, where you must nail and tie a stick, which should be half an inch broad at the middle, and run a little narrow to the ends: these sticks must have their ends turned upwards, so that the cases may turn horizontally on their centres. At the opposite sides of the cases, at each end, bore a hole close to the clay with a gimlet, the size of the neck of a common case of the same nature; from these holes draw a line round the case, and at the under part of the case bore a hole with the same gimlet, within one-half diameter of each line towards the centre; then from one hole to the other draw a right line. When you fire tourbillons, lay them on a smooth table, with their sticks downwards, and burn the leader through the middle with a port-fire. They should spin three or four seconds on the table before they rise, which is about the time the composition will be burning from the side-holes to those at bottom.

To tourbillons may be fixed reports in this manner: In the centre of the case at top make a small hole, and in the middle of the report make another; then place them together, and tie on the report, and with a single paper secure it from fire: this done, your tourbillon is completed. By this method you may fix on tourbillons small cones of stars, rain, &c. but be careful not to load them too much. One-eighth of an inch will be enough for the thickness of the sticks, and their length equal to that of the cases.

51. *Of pots des brins.* These are formed of pasteboard, and must be rolled pretty thick. They are usually made three or four inches in diameter, and four diameters long, and pinched with a neck at one end, like common cases. A number of these are placed on a plank, thus: Having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg; through all the holes run a quick-match, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that when lighted at one end it may discharge the whole almost instantaneously. In all the pots put about 1 oz. of meal and corn powder, then put in some stars, and in others rains, snakes, serpents, crackers, &c.; when they are all loaded, paste paper over their mouths. Two or three hundred of these pots being fired together make a very pretty show, by affording so great a variety of fires.

52. *Pots des saucissons.* These are generally fired out of large mortars without chambers, the same as those for aigrettes, only somewhat stronger. Saucissons are made of one and two ounce cases, five or six inches long, and choked in the same manner as serpents. Half the number which the mortar contains must be driven $1\frac{1}{2}$ diameter with composition, and the other half two diameters, so that when fired they may give two volleys of reports.

Different kinds of rockets.

53. *To fix one rocket on the top of another.* When sky-rockets are thus managed, they are called towering rockets, on account of their mounting so very high. Towering rockets are made after this manner: Fix on a pound-rocket a head without a collar; then take a four-ounce rocket, which may be headed or bounced, and rub the mouth of it with meal-powder, wetted with spirit of wine; when done, put it in the head of the large rocket with its mouth downwards; but before you put it in, stick a bit of quick-match in the hole of the clay of the pound-rocket, which match should be long enough to go a little way up the bore of the small rocket, to fire it when the large one is burnt out. The four-ounce rocket being too small to fill the head of the other, roll round it as much tow as will make it stand upright in the centre of the head: the rocket being thus fixed, paste a single paper round the opening of the top of the head of the large rocket. The large rocket must have only half a diameter of charge rammed above the piercer; for, if filled to the usual height, it would turn before the small one takes fire, and entirely destroy the intended effect. When one rocket is headed with another, there will be no occasion for any blowing powder; for the force with which it sets off will be sufficient to disengage it from the head of the first-fired rocket. The sticks for these rockets must be a little longer than for those headed with stars, rains, &c.

54. *Caduceus rockets,* in rising, form two spiral lines, or a double worm, by reason of their being placed obliquely, one opposite the other; and their counterpoise in their centre, which causes them to rise in a vertical direction. Rockets for this purpose must have their ends choked close, without either head or bounce, for a weight at top would be a great obstruction to their mounting.

55. *Signal sky-rockets* are made of several kinds, according to the different signals intended to be given; but in artificial fire-works, two sorts only are used, which are one with reports and the other without; but those for the use of the navy and army are headed with stars, serpents, &c. Rockets which are to be bounced must have their cases made $1\frac{1}{2}$ or 2 diameters longer than the common proportion; and after they are filled, drive in a double quantity of clay, then bounce and pinch them after the usual manner, and fix on each a cap. Signal sky-rockets without bounces, are only sky-rockets closed and capped. These are very light, therefore do not require such heavy sticks as those with loaded heads; for which reason you may cut one length of the rocket off the stick, or else make them thinner. Signal rockets with reports are fired in small flights; and often both these, and those without reports, are used for a signal to begin firing a collection of works.

56. *To fire sky-rockets without sticks.* You must have a stand of a block of wood, a foot diameter, and make the bottom flat, so that it may stand steady. In the centre of the top of this block draw a circle $2\frac{1}{2}$ inches diameter, and divide the circumference of it into three equal parts; then take 3 pieces of thick iron wire, each about 3 feet long, and drive them into the block, 1 at each point made on the circle; when these wires are driven in deep enough to hold them fast and upright, so that the distance from one to the other is the same at top as at bottom, the stand is complete. The stand being thus made, prepare your rockets thus: take some common sky-rockets, of any size, and head them as you please; then get some balls of lead, and tie to each a small wire 2 or $2\frac{1}{2}$ feet long, and the other end of each wire tie to the neck of a rocket. These balls answer the purpose of sticks when made of a proper weight, which is about 2-3ds the weight of the rocket; but when they are of a proper size, they will balance the rocket in the same manner as a stick, at the usual point of poise. To fire these, hang them one at a time, between the tops of the wires, letting their heads rest on the point of the wires, and the balls hang down between them. If the wires should be too wide for the rockets, press them together till they fit; and if too close, force them open. The wires for this purpose must be softened, so as not to have any spring, or they will not keep their position when pressed close or opened.

Aquatic fire-works.

57. *Water rockets* may be made from 4 oz. to 2 lb. If larger they are too heavy, so that it will be difficult to make them keep above water without a cork float, which must be tied to the neck of the case; but the rockets will not drive so well with as without floats. Cases for these are made in the same manner and proportion as for sky-rockets, only a little thicker of paper. When you fill those which are driven solid, put in first one ladleful of slow fire, then two of the proper charge, and on that one or two ladles of sinking charge, then the proper charge, then the sinking charge again, and so on till you have filled the case within three diameters; then drive on the composition one ladleful of clay,

through which make a small hole to the charge; then fill the case within half a diameter with corn-powder, on which turn down two or three rounds of the case in the inside; then pinch and tie the end very tight: having filled your rockets according to the above directions, dip their ends in melted rosin or sealing-wax, or else secure them well with grease. When you fire those rockets, throw in six or eight at a time; but, if you would have them all sink, or swim, at the same time, you must drive them with an equal quantity of composition, and fire them all together.

58. *To make pipes of communiction, which may be used under water.* Pipes for this purpose must be a little thicker of paper than those for land. Having rolled a sufficient number of pipes, and kept them till dry, wash them over with drying oil, and set them to dry; but when you oil them, leave about 1½ inch at each end dry, for joints: if they were oiled all over, when you come to join them the paste would not stick where the paper is greasy. After the leaders are joined, and the paste dry, oil the joints. These pipes will lie many hours under water, without receiving any damage.

59. *Horizontal wheels for the water.* First get a large wooden bowl without a handle; then have an octagon wheel made of a flat board 18 inches in diameter, so that the length of each side will be near seven inches: in all the sides cut a groove for the cases to lie in. This wheel being made, nail it on the top of the bowl; then take four 8-oz. cases, filled with a proper charge, each about six inches in length. Now, to clothe the wheel with these cases, get some whitish-brown paper, and cut it into slips four or five inches broad and seven or eight long. These slips being pasted all over on one side, take one of the cases, and roll one of the slips of paper about 1½ inch on its end, so that there will remain about 2½ inches of the paper hollow from the end of the case: this case tie on one of the sides of the wheel, near the corners of which must be holes bored, through which you put the packthread to tie the cases. Having tied on the first case at the neck and end, put a little meal-powder in the hollow paper; then paste a slip of paper on the end of another case, the head of which put into the hollow paper on the first, allowing a sufficient distance from the tail of one to the head of the other for the pasted paper to bend without tearing; the second case tie on as you did the first, and so on with the rest, except the last, which must be closed at the end, unless it is to communicate to any thing on the top of the wheel, such as fire-pumps or brilliant fires, fixed in holes cut in the wheel, and fired by the last or second case, as the fancy directs; six, eight, or any number, may be placed on the top of the wheel, provided they are not too heavy for the bowl. Before you tie on the cases, cut the upper part of all their ends, except the last, a little shelving, that the fire from one may play over the other, without being obstructed by the case. Wheel-cases have no clay driven in their ends, nor pinched, but are always left open; only the last, or those which are not to lead fire, which must be well secured.

The devices in fire-works are endless, varying with the fancy of the operator; but in the above sketch we have given all the theory, and enough of the practice to enable any person to adopt with ease whatever in the art he may chance to see practised by others.

PYRUS, the *pear-tree*, a genus of the pentagynia order, in the icosandria class of plants, and in the natural method ranking under the 36th order, pomaceæ. The calyx is quinquefid; there are five petals; the fruit is an apple, inferior, quinquelocular, and polyspermous. To this genus Linnæus has joined the apple and quince. There are 13 species; the most remarkable are:

1. The communis, or common pear-tree. Under this species are comprehended almost endless varieties. They bear their flowers and fruit upon spurs, arising from the sides of the branches from two or three years old and upwards; the same branches and spurs continuing fruitful for a great number of years. The different varieties furnish fruit for use from the beginning of July till the months of May and June next year; which, according to their times of ripening, may be divided into three classes, summer-pears, autumn-pears, and winter-pears. The summer-pears ripen in different sorts from the beginning of July until the middle or end of September, and are generally fit to eat from the tree, or at least do not keep a week or two before they rot. The autumn-pears come to their perfection in October, November, and December; some ripening nearly on the tree in October and the beginning of November, others requiring to lie some time in the fruitery, while some will keep two months; but all the winter-pears, though they attain their full growth on the tree by the end of October and in November, yet do not acquire perfection for eating till from the end of November to April and May. Those of each class have different properties; some being melting, others breaking, some mealy, and some hard and austere fit only for kitchen uses. As many of the finest sorts were first obtained from France, they are still continued in most catalogues by French names.

2. The malus, or common apple-tree. The varieties of this species are amazingly great with respect to the difference of the fruit. The botanists contend that the wilding, or crab-apple of the woods and hedges, is the original kind, and from the seeds of which the cultivated apple was first obtained. The varieties of this last no doubt are multiplied to some hundreds in different places, having been all first accidentally obtained from the seed or kernels of the fruit, and the approved sorts continued and increased by grafting upon crabs or any kind of apple-stocks; but although the number of varieties is very considerable, there are not above 40 or 50 sorts retained in the nurserymen's catalogues. These varieties arrive at full growth in successive order from July to the end of October, improve in perfection after being gathered, and several of the winter kinds in particular keep good for many months, even till the arrival of apples the next summer.

Among these various kinds of apples, some are used for the dessert, some for the kitchen, and some for cyder-making. Those used for the dessert are the following, placed as they successively ripen after one another. The white genneting, the margaret apple, the summer pearmain, the summer queening, the embroidered apple, the golden rennet, the summer white calville, the summer red calville, the silver pippin, the aromatic pippin, la reinette grise, la haute bonté, the royal russeting, Wheeler's russet, Sharp's russet, the spine apple, the golden pippin, the nonpareil, and the l'api or pomme d'api. Those for the kitchen use, in the order of their ripening, are these: the codlin, the summer marygold, the summer red pearmain, the Holland pippin, the Kentish pippin, the courpendu, Loan's pearmain, the French rennet, the French pippin, the royal russet, the monstrous rennet, the winter pearmain, the pome violette, Spencer's pippin, the stone pippin, and the oaken pippin. Those most esteemed for cyder are, the Devonshire royal wilding, the redstreak apple, the whitsour, the Herefordshire under-leaf; and the John apple, or deux annes, everlasting hanger, and gennet moyle.

The juice of apples is a menstruum for iron. A solution of iron in the juice of the apples called golden rennets, evaporated to a thick consistence, proves an elegant chalybeate, which keeps well.

The best method of preserving apples for winter use, is to let them hang upon the trees until there is danger of frost, to gather them in dry weather, and then to lay them in large heaps to sweat for a month or six weeks. They ought then to be carefully looked over, all which have the least appearance of decay taken out, the sound fruit wiped dry, and packed up in large oil-jars, which have been thoroughly scalded and dry, and then stopped close to exclude the air. If this plan is duly observed, the fruit will keep a long time sound, and their flesh remain plump; whereas, when exposed to the air, their skins will shrivel, and their pulp soften.

3. The coronaria, or sweet-scented crab of Virginia, grows 12 or 15 feet high, having angular, serrated leaves, pedunculated umbels of whitish-red, sweet-scented flowers, succeeded by small round crabs, remarkably sour and austere. There is one variety, called the evergreen Virginian crab-tree.

4. The cydonia, or quinces, of which there are three varieties.

All the varieties of the pear-tree are hardy, and will succeed in any common soil of a garden or orchard. They are propagated by grafting and budding upon any kind of pear-stocks; also occasionally upon quince-stocks, and sometimes upon white-thorn stocks; but pear-stocks are generally preferable to all others for general use. All kinds of apples are propagated in the same manner, using apple-stocks instead of pear-stocks. They will succeed in any common soil of a garden or orchard, and in any free situation, except in a low and very moist soil, in which they are apt to canker, and very soon go off. In a friable loam they are generally very successful.

PYTHIAN GAMES, in antiquity, solemn games celebrated near Delphi, in honour of Apollo, and in remembrance of his having killed the serpent Python.

These were held every two years, abou the month of Elaphebolion, which answeet to our February. The celebration of these games was attended with the Pythian song, in which was celebrated the fight of Apollo and the serpent. The victors were crowned with branches of laurel; though, at the first institution, the crown was of beech-leaves. See Game.

Q

Q, or q, the sixteenth letter of our alphabet. As a numeral it stands for 500; and with a dash over it, thus $\overline{Q}$, for 500000. Used as an abbreviature, q signifies quantity, or quantum: thus, among physicians, q. pl. is quantum placet, *i. e.* as much as you please of a thing; and q. s. quantum sufficit, *i. e.* as much as is necessary. Q. E. D. among mathematicians, is quod erat demonstrandum, *i. e.* which was to be demonstrated; and Q. E. F. quod erat faciendum, *i. e.* which was to be done. Q. D. among grammarians, is quasi dictum, *i. e.* as if it was said, or, as who should say. In the notes of the antients, Q stands for Quintus, or Quintius; Q. B. V. for quod bene vertat; Q. S. S. S. for quæ supra scripta sunt; Q. M. for Quintus Mutius, or quomodo; Quint. for Quintilius; and Quæs. for quæstor.

QUADRANGLE, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the as, or pound.

QUADRANT, in geometry, is either the quarter or fourth part of a circle, or the fourth part of its circumference; the arch of which therefore contains 90 degrees.

Quadrant also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also taking angles in surveying, heights and distances, &c.

This instrument is variously contrived, and furnished with different apparatus, according to the various uses it is intended for; but they have all this in common, that they consist of the quarter of a circle, whose limb or arch is divided into 90°, &c. Some have a plummet suspended from the centre, and are furnished either with plain sights, or a telescope to look through.

The principal and most useful quadrants are as follows:

Quadrant, *the common, or surveying.* This instrument ABC, fig. 1. Plate Quadrants, is made of brass, or wood, &c.: the limb or arch of which BC is divided into 90°, and each of these is farther divided into as many equal parts as the space will allow, either diagonally or otherwise. To one of the radii AC, are fitted two moveable sights; and to the centre is sometimes also annexed a label, or moveable index, AD, bearing two other sights; but instead of these last sights, there is sometimes fitted a telescope. Also from the centre hangs a thread with a plummet; and on the under side or face of the instrument are fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. But besides the parts above described, there is often added on the face, near the centre, a kind of compartment EF, called a quadrat, or geometrical square, which is a kind of separate instrument, and is particularly useful in altimetry and longimetry, or measuring heights and distances.

This quadrant may be used in different situations; in each of them, the plane of the instrument must be set parallel to that of the eye and the objects whose angular distance is to be taken. Thus, for observing heights or depths, its plane must be disposed vertically, or perpendicular to the horizon; but to take horizontal angles or distances, its plane must be disposed parallel to the horizon.

Again, heights and distances may be taken two ways, viz. by means of the fixed sights and plummet, or by the label; as also, either by the degrees on the limb, or by the quadrat. Thus, fig. 2 shews the manner of taking an angle of elevation with this quadrant; the eye is applied at C, and the instrument turned vertically about the centre A, till the object R is seen through the sights on the radius AC; then the angle of elevation RAH, made with the horizontal line KAH, is equal to the angle BAD, made by the plumb line and the other radius of the quadrant, and the quantity of it is shewn by the degrees in the arch BD cut off by the plumb line AD.

Quadrant, *astronomical.* See Observatory.

Quadrant, *Cole's*, is a very useful instrument, invented by Mr. Benjamin Cole. It consists of six parts, viz. the staff AB, fig. 3; the quadrantal arch DE; three vanes A, B, C; and their vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is also of wood, and is divided into degrees and third parts of degrees, to a radius of about nine inches; and to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, about which it easily moves. The sight-vane A is a thin piece of brass, near two inches in height and one broad, set perpendicularly on the end of the staff A, by means of two screws passing through its foot. In the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizontal vane B is about an inch broad, and two inches and a half high, having a slit cut through it of near an inch long, and a quarter of an inch broad; this vane is fixed in the centre-pin of the instrument, in a perpendicular position, by means of two screws passing through its foot, by which its position with respect to the sight-vane is always the same, their angle of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one which serves as an arm, is about $4\frac{1}{2}$ inches long, and $\frac{3}{4}$ of an inch broad; being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin. The other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate, at about half an inch distance from that end next the arch; this vane may be used either by its shade, or by the solar spot cast by a convex lens placed in it. And because the wood-work is often subject to warp or twist, therefore this vane may be rectified by means of a screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner: set the line G on the vernier against a degree of the upper limb of the quadrant; and turn the screw on the backside of the limb forward or backward, till the hole in the sight-vane, the centre of the glass, and the sunk spot in the horizon-vane, lie in a right line.

To find the sun's altitude by this instrument. Turn your back to the sun, holding the staff of the instrument with the right hand, so that it is in a vertical plane passing through the sun; apply one eye to the sight-vane looking through that and the horizon-vane till the horizon is seen; with the left hand slide the quadrantal arch upwards, till the solar spot or shade, cast by the shade-vane, falls directly upon the spot or slit in the horizon-vane; then will that part of the quadrantal arch which is raised above G or S (according as the observation respects either the solar spot or shade), shew the altitude of the sun at that time. But for the meridian altitude, the observation must be continued; and as the sun approaches the meridian, the sea will appear through the horizon-vane, which completes the observation; and the degrees and minutes, counted as before, will give the sun's meridian altitude; or the degrees counted from the lower limb upwards, will give the zenith distance.

Quadrant, *Collins's or Sutton's*, fig. 4, is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole; and fitted to the latitude of London. The lines running from right to left, are parallels of altitude; and those crossing them are azimuths. The smaller of the two circles bounding the projection, is one quarter of the tropic of Capricorn; and the greater is a quarter of the tropic of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and by having the sun's altitude, the hour of the day may here be found to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the sun's declination. On the projection are placed several of the most remarkable fixed stars between the tropics; and the next below the projection are the quadrant and line of shadows.

To find the time of the sun's rising or setting, his amplitude, his azimuth, hour of the day, &c. by this quadrant. Lay the thread on the day of the month, and bring the bead to the proper ecliptic, either of summer or winter, according to the season, which is called rectifying; then by moving the thread bring the bead to the horizon, in which case the thread will cut the limb in the point of the time of the sun's rising or setting before or after 6; and at the same time the bead will cut the horizon in the degrees of the sun's amplitude. Again, observing the sun's altitude with the quadrant, and supposing it found to be 45° on the 5th of May, lay the thread over the 5th of May, then bring the bead to the summer ecliptic, and carry it to the parallel of altitude 45°; in which case the thread will cut the limb at 55° 15′, and the hour will be seen among the hour-lines to be either 41 m. past 9 in the morning, or 19 m. past 2 in the afternoon. Lastly, the bead shews among the azimuths the sun's distance from the south 50° 41′.

But if the sun's altitude is less than what it is at 6 o'clock, the operation must be performed among those parallels above the upper horizon; the bead being rectified to the winter ecliptic.

Quadrant, *gunner's*, fig. 5, sometimes called the gunner's square, is used for elevating and pointing cannon, mortars, &c. and consists of two branches, either of wood or brass, between which is a quadrantal arch divided into 90°, and furnished with a thread and plummet.

The use of this instrument is very easy; for if the longer branch, or bar, is placed in the mouth of the piece, and it is elevated till the plummet cuts the degree necessary to hit a proposed object, the thing is done.

Sometimes on the sides of the longer bar, are noted the division of diameters and weights of iron balls, as also the bores of pieces.

Quadrant, *Gunter's*, so called from its inventor, Edmund Gunter, (fig. 6) besides the apparatus of other quadrants, has a stereographic projection of the sphere on the plane of the equinoctial; and also a calendar of the months, next to the divisions of the limb; by which, besides the common purposes of other quadrants, several useful questions in astronomy, &c. are easily resolved.

Use of Gunter's quadrant. 1. To find the sun's meridian altitude for any given day, or conversely the day of the year answering to any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; then the degree it cuts in the limb is the sun's meridian altitude. And, contrariwise, the thread being set to the meridian altitude, it shews the day of the month.

2. To find the hour of the day. Having put the bead, which slides on the thread, to the sun's place in the ecliptic, observe the sun's altitude by the quadrant; then if the bead is laid over the same in the limb, the bead will fall upon the hour required. On the contrary, laying the bead on a given hour, having first rectified or set it to the sun's place, the degree cut by the thread on the limb gives the altitude.

Note: the bead may be rectified otherwise, by bringing the thread to the day of the month, and the bead to the hour-line of 12.

3. To find the sun's declination from his place given, and the contrary. Bring the bead to the sun's place in the ecliptic, and move the thread to the line of declination ET, so shall the bead cut the degree of declination required. On the contrary, the bead being adjusted to a given declination, and the thread moved to the ecliptic, the bead will cut the sun's place.

4. The sun's place being given, to find the right ascension, or contrariwise. Lay the thread on the sun's place in the ecliptic, and the degree it cuts on the limb is the right ascension sought. And the converse.

5. The sun's altitude being given, to find his azimuth, and contrariwise. Rectify the bead for the time, as in the second article, and observe the sun's altitude; bring the thread to the complement of that altitude; then the bead will give the azimuth sought, among the azimuth-lines.

Quadrant, *Hadley's*, (fig. 7) so called from its inventor, John Hadley, esq. is now universally used, as the best of any for nautical and other observations.

Description of Hadley's quadrant. Fig. 7, represents a quadrant, or octant, of the common construction. The following parts are those which require the particular attention of the observer:

I. BC the arc.
II. AD the index, *ab* the nonius scale.
III. E the index-glass.
IV. F the fore horizon-glass.
V. G the back horizon-glass.
VI. K the dark glasses or screens.
VII. HI the vanes or sights.
VIII. The arc BC is called the limb or quadrantal arc; the arc *cd*, lying from *o* towards the right, is called the arc of excess.

The quadrant consists of an arc BC, firmly attached to two radii, or bars, AB, AC, which are strengthened and bound together by the two braces LM.

The index D is a flat bar of brass, that turns on the centre of the octant. At the lower end of the index there is an oblong opening: to one side of this opening a vernier is fixed, to subdivide the divisions of the arc; at the bottom or end of the index there is a piece of brass, which bends under the arc, carrying a spring to make the vernier lie close to the divisions: it is also furnished with a screw to fix the index in any desired position. See Vernier.

The circular arcs on the arc of the quadrant are drawn from the centre on which the index turns: the smallest excentricity in the axis of the index would be productive of considerable errors.

The position of the index on the arc after an observation, points out the number of degrees and minutes contained in the observed angle.

Upon the index E, and near its axis, is fixed a plain speculum, or mirror of glass, quicksilvered. It is set in a brass frame, and is placed so that the face of it is perpendicular to the plane of the instrument; this mirror being fixed to the index, moves along with it, and has its direction changed by the motion thereof.

This glass is designed to receive the image of the sun, or any other object, S, and reflect it upon either of the two horizon-glasses F and G, according to the nature of the observation.

The brass frame with the glass is fixed to the index by the screw C; the other screw serves to replace it in a perpendicular position, if by any accident it has been deranged.

The index-glass is often divided into two parts, the one silvered, the other black with a small screen in front. A single black surface has indeed some advantages; but if the glasses are well selected, there is little danger to be apprehended of error from a want of parallelism; more is to be feared from the surfaces not being flat.

On the radius AB of the octant, are two small speculums F and G. The surface of the upper one is parallel to the index-glass, when the counting division of the index is at *o* on the arc; but the surface of the lower one is perpendicular to the index-glass, when the index is at 0 degrees on the arc; these mirrors receive the reflected rays from the object, and transmit them to the observer.

The horizon-glasses are not entirely quicksilvered; the upper one F, is only silvered on its lower part, or that half next the quadrant, the other half being transparent; and the back part of the frame is cut away, that nothing may impede the sight through the unsilvered part of the glass. The edge of the foil of this glass is nearly parallel to the plane of the instrument, and ought to be very sharp, and without a flaw.

The other horizon-glass G, is silvered at both ends; in the middle there is a transparent slit, through which the horizon, or other object, may be seen.

Each of these glasses is set in a brass frame, to which there is an axis; this axis passes through the wood-work, and is fitted to a lever on the under side of the quadrant; by this lever the glass may be turned a few degrees on its axis, in order to set it parallel to the index-glass. The lever has a contrivance to turn it slowly, and a button to fix it. To set the glasses perpendicular to the plane of the quadrant, there are two sunk screws, one before and one behind each glass; these screws pass through the plate on which the frame is fixed, into another plate; so that by loosening one and tightening the other of these screws, the direction of the frame with its mirror may be altered, and thus be set perpendicular to the plane of the instrument.

There are two red or dark glasses, and one green one K; they are used to prevent the bright rays of the sun, or the glare of the moon, from hurting the eye at the time of observation. They are each of them set in a brass frame, which turns on a centre; so tha they may be used separately, or together, as the brightness of the sun may require. The green glass may be used also alone, if the sun is very faint; it is also used for taking the altitude of the moon, and in ascertaining her distance from a fixed star.

When these glasses are used for the fore observation, they are fixed as at K; when used for the back observation, they are removed to N.

Each of the vanes H and I, is a perforated piece of brass, designed to direct the sight parallel to the plane of the quadrant. That which is fixed at I is used for the fore, the other for the back, observation.

The vane I has two holes: one exactly at the height of the quicksilvered edge of the horizon-glass; the other somewhat higher, to direct the sight to the middle of the transparent part of the mirror, for those objects which are bright enough to be reflected from the unsilvered part of the mirror.

Directions to hold the instrument. It is recommended to support the weight of the instrument by the right hand, and reserve the left to govern the index. Place the thumb of the right hand against the edge of the quadrant, under the swelling part of which the fore sight I stands, extending the fingers across the back of the quadrant, so as to lay hold on the opposite edge, placing the fore finger above, and the other fingers below the swelling part, or near the fore horizon-glass; thus you may support the instrument conveniently, in a vertical position, by the right hand only; by resting the thumb of the left hand against the side, or the fingers against the middle bar, you may move the index gradually either way.

In the back observation, the instrument should be supported by the left hand, and the index be governed by the right.

Of the two objects which are made to coincide by this instrument, the one is seen directly by a ray passing through, the other by a ray reflected from, the same point of the horizon-glass to the eye. This ray is called the visual ray; but when it is considered merely as a line drawn from the middle of the horizon-glass to the eye-hole of the sight vane, it is called the axis of vision.

The axis of a tube, or telescope, used to direct the sight, is also called the axis of vision.

The quadrant, if it is held as before directed, may be easily turned round between the fingers and thumb, and thus nearly on a line parallel to the axis of vision; thus the plane of the quadrant will pass through the two objects when an observation is made, a circumstance absolutely necessary, and which is more readily effected when the instrument is furnished with a telescope. Within the telescope are two parallel wires, which by turning the eye-glass tube may be brought parallel to the plane of the quadrant, so that by bringing the object to the middle between them, you are certain of having the axis of vision parallel to the plane of the quadrant.

Of the observations. There are two sorts of observations to be made with this instrument: the one is when the back of the observer is turned towards the object, and therefore called the back observation; the other when the face of the observer is turned towards the object, which is called the fore observation.

To rectify the instrument for the fore observation. Slacken the screw in the middle of the handle behind the glass F; bring the index close to the button h; hold the instrument in a vertical position, with the arch downwards; look through the right-hand hole in the vane I, and through the transparent part of the glass F, for the horizon; and if it lies in the same right line with the image of the horizon seen on the silvered part, the glass F is rightly adjusted; but if the two horizontal lines disagree, turn the screw which is at the end of the handle backward or forward, till those lines coincide; then fasten the middle screw of the handle, and the glass is rightly adjusted.

To take the sun's altitude by the fore observation, Having fixed the screens above the horizon-glass F, and suited them proportionally to the strength of the sun's rays, turn your face towards the sun, holding the instrument with your right hand, by the braces L and M, in a vertical position, with the arch downward; put your eye close to the right-hand hole in the vane I, and view the horizon through the transparent part of the horizon-glass F, at the same time moving the index D with the left hand, till the reflex solar spot coincides with the line of the horizon; then the degrees counted from that end next your body, will give the sun's altitude at that time, observing to add or subtract 16 minutes according as the upper or lower edge of the sun's reflex image is made use of.

But to get the sun's meridian altitude, which is the thing wanted for finding the latitude, the observations must be continued; and as the sun approaches the meridian, the index D must be continually moved towards B, to maintain the coincidence between the reflex solar spot and the horizon; and consequently as long as this motion can maintain the same coincidence, the observation must be continued till the sun has reached the meridian, and begins to descend, when the coincidence will require a retrograde motion of the index, or towards C; and then the observation is finished, and the degrees counted as before will give the sun's meridian altitude, or those from B will give the zenith distance; observing to add the semidiameter, or 16′, when his lower edge is brought to the horizon, or to subtract 16 when the horizon and upper edge coincide.

To take the altitude of a star by the fore observation. Through the vane H, and the transparent slit in the glass G, look directly to the star; and at the same time move the index, till the image of the horizon behind you, being reflected by the great speculum, is seen in the silvered part of G, and meets the star; then will the index shew the degrees of the star's altitude.

To rectify the instrument for the back observation. Slacken the screw in the middle of the handle, behind the glass G; turn the button h on one side, and bring the index as many degrees before 0 as are equal to double the dip of the horizon at your height above the water; hold the instrument vertical, with the arch downward; look through the hole of the vane H; and if the horizon seen through the transparent slit in the glass G, coincides with the image of the horizon seen in the silvered part of the same glass, then the glass G is in its proper position; but if not, set it by the handle, and fasten the screw as before.

To take the sun's altitude by the back observation. Put the screens as at K; and in proportion to the strength or faintness of the sun's rays, let either one or both or neither of the frames of those glasses be turned close to the face of the limb; hold the instrument in a vertical position, with the arch downward, by the braces L and M, with the left hand; turn your back to the sun, and put one eye close to the hole in the vane H, observing the horizon through the transparent slit in the horizon-glass G; with the right hand move the index D, till the reflected image of the sun is seen in the silvered part of the glass G, and in a right line with the horizon; swing your body to and fro, and if the observation is well made, the sun's image will be observed to brush the horizon, and the degrees reckoned from C, or that part of the arch farthest from your body, will give the sun's altitude at the time of observation; observing to add 16′, or the sun's semidiameter, if the sun's upper edge is used, and subtract the same for the lower edge.

The direction just given, for taking altitudes at sea, would be sufficient, but for two corrections that are necessary to be made before the altitude can be accurately determined, viz. one on account of the observer's eye being raised above the level of the sea, and the other on account of the refraction of the atmosphere, especially in small altitudes.

The following tables, therefore, shew the corrections to be made on both these accounts:

TABLE I. Dip of the horizon of the sea.			TABLE II. Refractions of the stars, &c. in altitude.					
Height of the eye.	Dip of the horizon.		Appar. altit. in deg.	Refraction.		App. alt. in deg.	refraction.	
Feet.	′	″	°	′	″	°	′	″
1	0	57	0	33	0	11	4	47
2	1	21	¼	30	35	12	4	23
3	1	39	½	28	22	15	3	30
5	2	8	1	24	29	20	2	35
10	3	1	2	18	35	25	2	2
15	3	42	3	14	36	30	1	38
20	4	16	4	11	51	35	1	21
25	4	46	5	9	54	40	1	8
30	5	14	6	8	29	45	0	57
35	5	39	7	7	20	50	0	48
40	6	2	8	6	29	60	0	33
45	6	24	9	5	48	70	0	21
50	6	44	10	5	15	80	0	10

General rules for these corrections. 1. In the fore observations, add the sum of both corrections to the observed zenith distance, for the true zenith distance; or subtract the said sum from the observed altitude, for the true one. 2. In the back observation, add the dip and subtract the refraction for altitudes; and for zenith distances do the contrary, viz. subtract the dip, and add the refraction.

Example. By a back observation, the altitude of the sun's lower edge was found by Hadley's quadrant to be 25° 12′, the eye being 30 feet above the horizon. By the tables, the dip on 30 feet is 5′ 14″, and the refraction on 25° 12′ is 2′ 1″. Hence

Appar. alt. lower limb	25°	12′	0″
Sun's semidiameter, sub.	0	16	0
Appar. alt. of centre	24	56	3
Dip of horizon, add	0	5	14
	25	1	14
Refraction, subtract	0	2	1
True alt. of centre	24	59	13

In the case of the moon, besides the two corrections above, another is to be made for her parallaxes. But for all these particulars, see the requisite tables for the Nautical Almanac; also Robertson's Navigation, vol. 2, pa. 340, &c. edit. 1780.

2. Sinical quadrant is one of some use in navigation. It consists of several concentric quadrantal arches, divided into eight equal parts, by means of radii, with parallel right lines crossing each other at right angles. Now any one of the arches, as BC, fig. 8. in the Plate, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then BC is taken for a quadrant of the horizon, either of the sides, as AB, may represent the meridian, and the other side AC will represent a parallel, or line of east and west; all the other lines parallel to AB will be also meridians; and all those parallel to AC, east and west lines, or parallels. Again, the eight species into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11° 15′. The arch BC is likewise divided into 90°, and each degree subdivided into 12′, diagonalwise. To the centre is fixed a thread, which being laid over any degree of the quadrant, serves to divide the horizon.

If the sinical quadrant is taken for a fourth part of the meridian, one side of it AB may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degrees of the circumference BC will represent degrees of latitude; and the parallels to the side AB assumed from every point of latitude to the axis, AC, will be radii of the parallels of latitudes, as likewise the cosine of those latitudes.

Hence, suppose it is required to find the degrees of longitude contained in 83 of the lesser leagues in the parallel of 48°; lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues on AB, beginning at A; this will terminate in H, allowing every small interval four leagues. Then tracing out the parallel HE, from the point H to the thread; the part AE of the thread shews that 125 greater or equinoctial leagues make 6° 15′; and therefore that the 83 lesser leagues AH, which make the difference of longitude of the course, and are equal to the radius of the parallel HE, make 6° 15′ of the said parallel.

When the ship sails upon an oblique course, such course, beside the north and south greater leagues, gives lesser leagues easterly and westerly, to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but on all the intermediate ones, there must be found a mean proportional parallel between them. To find this, there is on the instrument a scale of cross latitudes. Suppose then it were required to find a mean parallel between the parallels of 40° and 60°; take with the compasses the middle between the 40th and 60th degree on the scale; this middle point will terminate against the 51st degree, which is the mean parallel sought.

The chief use of the sinical quadrant is, to form upon it triangles similar to those made by a ship's way with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants, and the lines N and S, E and W; and every 5th line and arch are made deeper than the rest. Now suppose a ship has sailed 150 leagues north-east by north, or making an angle of 33° 45′ with the north part of the meridian; here are given the course and distance sailed, by which a triangle may be formed on the instrument similar to that made by the ship's course; and hence the unknown parts of the triangle may be found. Thus, supposing the centre A to represent the place of departure, count by means of the concentric circles along the point the ship sailed on, viz. AAD, 150 leagues; then in the triangle AED, similar to that of the ship's course, find AE = difference of latitude, and DE = difference of longitude, which must be reduced according to the parallel of latitude come to.

Quadrant *of altitude* is an appendix to the artificial globe, consisting of a thin slip of brass, the length of a quarter part of one of the great circles of the globe, and graduated. At the end, where the division terminates, is a nut riveted on, and furnished with a screw, by means of which the instrument is fitted on the meridian, and moveable round upon the rivet to all points of the horizon, as represented in the figure referred to. Its use is to serve as a scale in measuring of altitudes, amplitudes, azimuths, &c.

QUADRANTAL, in Roman antiquity, a vessel every way square like a die, serving as a measure of liquids; its capacity was eighty libræ or pounds of water, which made 48 sextaries, two urnæ, or eight congii.

QUADRAT, a mathematical instrument, called also a geometrical square, and line of shadows; it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrant; but we shall describe it by itself, as being a distinct instrument.

It is made of any solid matter, as brass, wood, &c. or of any four plane rules joined together at right angles, as represented in Plate Quadrant's fig. 9, where A is the centre, from which hangs a thread with a small weight at the end, serving as a plummet. Each of the sides BE and DE is divided into a hundred equal parts, or if the sides are long enough to admit of it, into a thousand parts; C and F are two sights, fixed on the side AD. There is, moreover, an index AH, which, when there is occasion, is joined to the centre A, in such a manner that it can be moved freely round, and remain in any given situation. On this instrument are two sights K, L, perpendicular to the right line going from the centre of the instrument. The side DE is called the upright side, or the line of the direct or upright shadows; and the side BE is termed the reclining side, or the line of the versed or back shadows.

To measure an accessible height AB, fig. 10. by the quadrat, let the distance BD be measured, which suppose = 96 feet, and let the height of the observer's eye be six feet; then holding the instrument with a steady hand, or rather resting it on a support, let it be directed towards the summit A, so that it may be seen clearly through both sights; the perpendicular or plumb-line meanwhile hanging free, and touching the surface of the instrument; let now the perpendicular be supposed to cut off on the upright side KN 80 equal parts; it is evident that LKN, ACK, are similar triangles, and by prop. 4. lib. 6. of Euclid, NK : KL : : KC (*i.e.* BD) : CA; that is, 80 : 100 : : 96 : CA; therefore by the rule of three, $CA = \frac{96 \times 100}{80} = 120$ feet; and CB, the height of the observer's eye, = 6 feet, being added, the whole height BA is 126 feet.

If the observer's distance, as DE, is such that, when the instrument is directed as formerly towards the summit A, the perpendicular falls on the angle P, and the distance BE or CG is 120 feet, CA will also be 120 feet; for PG : GH : : GC : CA; but PG = GH, therefore GC = CA; that is, CA will be 120 feet, and the whole height BA = 126 feet as before.

But let the distance BF be 300 feet, and the perpendicular or plumb-line cut off 40 equal parts from the reclining side. Now, in this case, the angles QAC, QZI, are equal (29. 1. Eucl.), as are also the angles QZI, ZIS; therefore ∠ ZIS = QAC; but ZSI = QCA, as being both right: hence, in the equiangular triangles ACQ, SZI, we have (by 4. 6. Eucl.) ZS : SI : : CQ : CA; that is, 100 : 40 : : 300 : CA, or $CA = \frac{40 \times 300}{100} = 120$; and by adding six feet, the observer's height, the whole height BA will be 126 feet.

To measure any distance at land or sea by the quadrat. In this operation the index AH, fig. 9, is to be applied to the instrument, as was shown in the description; and by the help of a support, the instrument is to be placed horizontally at the point A, fig. 11. then let it be turned till the remote point F, whose distance is to be measured, is seen through the fixed sights; and bringing the index to be parallel with the other side of the instrument, observe through its sights any accessible mark B, at a distance; then carrying the instrument to the point B, let the immoveable sights be directed to the first station A, and the sights of the index to the point F. If the index cuts the right side of the square, as in K, the proportion will be (by 4. 6.) BR : RK : : BA (the distance of the stations to be measured with a chain) : AF, the distance sought. But if the index cuts the reclined side of the square in the point L, then the proportion is, LS : SB : : BA : AG, the distance sought; which accordingly may be found by the rule of three.

Quadrat, in printing, a piece of metal cast like the letters, to fill up the void spaces between words, &c. There are quadrats of different sizes, as *m* quadrats, *n* quadrats, &c. which are respectively of the dimensions of these letters.

QUADRATIC EQUATION, that wherein the unknown equality is of two dimensions, or raised to the second power. See Algebra.

QUADRATURE, in geometry, denotes the squaring, or reducing a figure to a square. Thus the finding of a square which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c.

The quadrature of curvilinear spaces, as the circle, ellipsis, parabola, &c. is a matter of much deeper speculation, making a part of the higher geometry; wherein the doctrine of fluxions is of singular use. See Fluxion.

Case I. Let ARC (Plate Quadrant, fig. 12.) be a curve of any kind, whose ordinates R*b*, CB, are perpendicular to the axis AB. Imagine a right line *b*R*g*, perpendicular to AB, to move parallel to itself from A towards B; and let the velocity thereof, or the fluxion of the absciss A*b*, in any proposed position of that line, be denoted by bd; then will bn, the rectangle under bd, and the ordinate bR, express the corresponding fluxion of the generating area AbR: which fluxion, if A$b = x$, and bR $= y$, will be $y\dot{x}$. From whence, by substituting for y or $\dot{x}$, according to the equation of the curve, and taking the fluent, the area itself AbR will become known.

But in order to render this still more plain, we shall give some examples, wherein x, y, z, and u, are all along put to denote the absciss, ordinate, curve line, and the area, respectively. Thus, if the area of a right-angled triangle is required, put the base AH (fig. 13,) $= a$, the perpendicular HM $= b$, and let AB $= x$ be any portion of the base considered as a flowing quantity; and let BR $= y$, be the ordinate, or perpendicular corresponding. Then, because of the similar triangles AHM and ABR, we shall have $a : b :: x : y = \frac{bx}{a}$. Whence, $y\dot{x}$, the fluxion of the area ABR, is, in this case, equal to $\frac{bx\dot{x}}{a}$; and consequently the fluent thereof, or the area itself, $= \frac{bx^2}{2a}$: which, therefore, when $x = a$, and BR coincides with HM, will become $\frac{ab}{2} = \frac{\text{AH} \times \text{HM}}{2} =$ the area of the whole triangle AHM; as is also demonstrable from the principles of common geometry.

Again, let the curve ARMH (fig. 14,) whose area you would find, be the common parabola; in which case, if AB $= x$, and BR $= y$, and the parameter $= a$, we shall have $y^2 = ax$, and $y = a^{\frac{1}{2}} x^{\frac{1}{2}}$: and therefore $\dot{u}\ (= y\dot{x}) = a^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$; whence $u = \frac{2}{3} \times a^{\frac{1}{2}} x^{\frac{3}{2}} = \frac{2}{3}\ a^{\frac{1}{2}} x^{\frac{1}{2}} \times x = \frac{2}{3} yx = \frac{2}{3} \times \text{AB} \times \text{BR}$. Hence a parabola is two-thirds of a rectangle of the same base and altitude.

The same conclusion might have been found more easily in terms of y: for $x = \frac{y^2}{a}$, and $\dot{x} = \frac{2y\dot{y}}{a}$; and consequently $\dot{u}\ (= y\dot{x}) = \frac{2y^2\dot{y}}{a}$; whence $u = \frac{2y^3}{a} = \frac{2y}{3} \times \frac{y^2}{n} = \frac{2y}{3} \times x = \frac{2}{3} \times \text{AB} \times \text{BR}$, as before.

Quadrature, in astronomy, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters.

Quadrature-lines are two lines placed on Gunter's sector: they are marked with Q. and 5, 6, 7, 8, 9, 10: of which Q. signifies the side of the square, and the other figures the side of the polygons of 5, 6, 7, &c. sides. S, on the same instrument, stands for the semidiameter of a circle, and 90 for a line equal to 90° in circumference.

QUADRATUS, in anatomy, a name given to several muscles on account of their square figures.

QUADRIGA, in antiquity, a car or chariot drawn by four horses. On the reverse of medals we frequently see the emperor or Victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called nummi quadrigati, and Victoriati.

QUADRILATERAL, in geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure. The quadrilateral figures are either a parallelogram, trapezium, rectangle, square, rhombus, or rhomboides.

QUADRILLE, a game at cards, sometimes called ombre by four; which chiefly differs from ombre by three, in being played by four persons; and having all the forty cards dealt out, to each person, at ten each.

The general laws of this game are, 1. It is not permitted to deal the cards any otherwise than four by three, the dealer being at liberty to begin with which of those numbers he pleases. 2. If he who plays either sans prendre, or calling a king, names a trump of a different suit from that his game is in, or names two several suits, that which he first named must be the trump. 3. He who plays must name the trump by its proper name, as he likewise must the king he calls. 4. He who has said I pass, must not be again admitted to play, except he plays by force, upon account of his having spadille. 5. He who has asked the question, and has leave given him to play, is obliged to do it; but he must not play sans prendre except he is forced to do it. 6. He who has the four kings may call the queen of either of his kings. 7. Neither the king nor queen of the suit which is trumps must be called. 8. He who has one or several kings, may call any king he has in his hand; in such case, if he wins, he alone must make six tricks; if he wins, it is all his own; and if he loses he pays all by himself. 9. Every one ought to play in his turn, but for having done otherwise no one must be beasted. 10. He, however, whose turn it is not to play, having in his hand the king the ombre has called, and who shall trump about with either spadille, manille, or basto, or shall even play down the king that was called, to give notice of his being the friend, must not pretend to undertake the vole; nay, he must be condemned to be beasted if it appears that he did it with any fraudulent design. 11. He who has drawn a card from his game, and presented it openly in order to play it, is obliged so to do, if his retaining it may be either prejudicial to the game, or give any intimation to the friend, especially if the card is a matadore; but he who plays sans prendre, or calls his own king, is not subject to this law. 12. None ought to look upon the tricks, nor to count aloud what has been played, except when it is his turn to play, but to let every one reckon for himself. 13. He who, instead of turning up the tricks before any one of his players, shall turn up and discover his game, must be equally beasted with him whose cards he had so discovered, the one paying one half and the other the like. 14. He who renounces must be beasted as many times as he has so done, but if the cards are mixed he is to pay but one beast. 15. If the renounce prejudices the game, and the deal is not played out, every one may take up his cards, beginning at the trick where the renounce was made, and play them over again. 16. He who shews the game before the deal is out must be beasted, except he plays sans prendre. 17. None of the three matadores can be commanded down by an inferior trump. 18. If he who plays sans prendre with the matadores in his hand, demands only one of them, he must receive only that he mentioned. 19. He who, instead of sans prendre, shall demand matadores, not having them; or he who shall demand sans prendre instead of matadores; cannot compel the players to pay him what is really his due. 20. Matadores are only paid when they are in the hands of the ombre, or of the king his ally, whether all in one hand, or separately in both. 21. He who undertakes the vole and does not make it, must pay as much as he would have received had he won it. 22. He who plays and does not make three tricks is to be beasted alone, and must pay all that is to be paid; and if he makes no tricks at all, he must also pay to his two adversaries the vole, but not to his friend.

QUADRUPEDS, in zoology, a class of land animals, with hairy bodies, and four limbs or legs proceeding from the trunk of their bodies; add to this, that the females of this class are viviparous, or bring forth their young alive, and nourish them with milk from their teats.

QUADRUPLE, a sum or number multiplied by four, or taken four times.

QUAKERS. By stat. 7 and 8 W. III. c. 27, and 8 G. I. c. 6. quakers making and subscribing the declaration of fidelity mentioned in 1 W. and M. shall not be liable to the penalty against others refusing to take such oaths: and not subscribing the declaration of fidelity, &c. they are disabled to vote at the election of members of parliament.

By 7 and 8 W. III. c. 34, made perpetual by 1 G. I. c. 6, quakers, where an oath is required, are permitted to make a solemn affirmation or declaration of the truth of any fact; but they are not capable of being witnesses in any criminal cause, serving on juries, or bearing any office or place of profit under government, unless they are sworn like other protestants; but this clause does not extend to the freedom of a corporation. 1 Lord Raym. 337.

By stat. 22 G. II. c. 46. an affirmation shall be allowed in all cases (except criminal) where by any act of parliament an oath is required, though no provision is therein made for admitting a quaker to make his affirmation. See Friends.

QUALEA, a genus of the monandria monogynia class and order. The calyx is four-parted; corolla two-petalled; fruit a berry. There are two species, trees of Guiana.

QUAMDIU SE BENE GESSERIT, a clause frequently to be found in letters patent of the grant of offices, as in those to the barons of the exchequer, &c. where it intimates that they shall hold the same as long as they shall behave themselves well. It is said that these words intend what the law would imply if an office was granted during life.

QUANTUM MERUIT, in law, is an action upon the case, founded on the necessity of paying a person for doing any thing as much as he deserves.

QUARE, in law, a term affixed to the title of several writs: as, 1. Quare ejecit infra terminum, is a writ that lies for a lessee cast out of his farm before his term is expired. 2. Quare impedit, a writ that lies for a person that has purchased an advowson, against him who disturbs him in the right thereof by presenting a clerk to it when the church is vacant. This writ differs from what is called a darrein presentment, because that is brought where a person or his ancestors formerly presented; but this lies for him that is purchaser himself. Yet in both these writs, the plaintiff recovers the presentation and damages; though the title to the advowson is recovered only by a quare impedit. 3. Quare incumbravit is a writ that lies against a bishop, who, within six months after the vacancy of a benefice, confers it on his clerk, while two others are contesting the right of presentation. 4. Quare non admisit is a writ that lies where any one has recovered an advowson or presentation, and sending his clerk to be admitted, the bishop refuses to admit him; in which case the person that has the presentation may have this writ agaist the bishop. 5. Quare non permittit is a writ that lies for one who has a right to present for a turn against the proprietary. 6. Quare obstruxit, is a writ that lies for him who, having a right to pass through another's grounds, cannot enjoy the same, because the owner has fenced them up.

QUARTER, the fourth part of any thing, the fractional expression for which is $\frac{1}{4}$. Quarter, in weights, is generally used for the fourth part of a hundredweight avoirdupois, or 28lb.

Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels.

QUARTER, in heraldry, is applied to the parts or members of the first division of a coat that is quartered or divided into four quarters.

QUARTER *of a point*, in navigation, is the fourth part of the distance between two cardinal points, which is 2° 48′.

QUARTER *of a ship*, is that part of a ship's hold which lies between the steerage-room and the transom.

QUARTER-MASTERS, or *quarteers*, in a ship of war, are officers whose business it is to rummage, stow, and trim, the ship in the hold; to overlook the steward in his delivery of victuals to the cook, and in pumping or drawing out beer, or the like. They are also to keep their watch duly, in conning the ship, or any other duty.

QUARTER-SESSIONS. See SESSIONS.

QUARTERING, in gunnery, is when a piece of ordnance is so traversed that it will shoot on the same line, or on the same point of the compass, as the ship's quarter bears.

QUARTERING, in heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, couping, &c. that is, by perpendicular and horizontal lines, &c.

QUARTERS, a name given at sea to the several stations where the officers and crew of a ship of war are posted in action.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are, in general, as follow, when the ship is well manned, so as to fight both sides at once occasionally:

Pounder		No. of men.
To a 42	-	15
32	-	13
24	-	11
18	-	9
12	-	7
9	-	6
6	-	5
4	-	4
3	-	3

This number, to which is often added a boy to bring powder to every gun, may be occasionally reduced, and the guns nevertheless well managed. The number of men appointed to the small arms on board his majesty's ships and sloops of war, by order of the admiralty, are:

Rate of the ship.		No. of men to the small arms.
1st	- - -	150
2d	- - -	120
3d of 80 guns	-	100
— of 70 guns	-	80
4th of 60 guns	-	70
4th	- - -	60
5th	- - -	50
6th	- - -	40
Sloops of war	-	30

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the sails. The boatswain, and a sufficient number of men, are stationed to repair the damaged rigging; and the gunner and carpenter, wherever necessary, according to their respective offices.

QUARTERS, *close*, in a ship, those places where the seamen quarter themselves, in case of boarding, for their own defence, and for clearing the decks, &c.

QUARTZ. This stone, which is very common in most mountainous countries, is sometimes crystallized, and sometimes amorphous. The primitive form of its crystals, according to Mr. Hauy, is a rhomboidal parallelopiped, the angles of whose rhombs are 94° and 86°, so that it does not differ much from a cube. The most common variety is a dodecahedron, composed of two six-sided pyramids, applied base to base, whose sides are isosceles triangles, having the angle at the vertex 40°, and each of the angles at the base 70°; the inclination of a side of one pyramid to the contiguous side of the other pyramid is 104°. There is often a six-sided prism interposed between the two pyramids, the sides of which always correspond with those of the pyramids. For a description and figure of the other varieties of quartz crystals, and for a demonstration of the law which they have followed in crystallizing, we refer the reader to Romé de Lisle and Mr. Hauy.

The texture of quartz is more or less foliated. Fracture conchoidal or splintery. Its lustre varies, and also its transparency, and in some cases it is opaque. It causes a double refraction. Specific gravity from 2.64 to 2.67, and in one variety 2.69. Its colour and appearance are exceedingly various: this has induced mineralogists to divide it into numerous varieties. The common division is into five subspecies.

1. Amethyst. Colour violet, of different degrees of intensity, sometimes greenish. Commonly found in crystals in the hollow cavities of agates. Composed, according to Rose, of 97.50 silica
0.25 alumina
0.50 oxide of iron and manganese

98.25

2. Rock crystal. Colourless, or white with different shades of grey, yellow, brown, and red. Usually crystallized in the hollows of veins. Transparency 3, 4. Composed, according to Bergman, of
93 silica
6 alumina
1 lime

100.

3. Milk and rosy red quartz. Colour usually red. Always in mass, never crystallized. Lustre greasy. Transparency 2, 3. Found in Bavaria and Finland. Supposed to contain manganese.

4. Common quartz. A constituent of many mountains. Colours exceedingly numerous, white, grey, brown, yellow, red, green of various shades. Usually amorphous; sometimes crystallized. Its transparency chiefly distinguishes it from rock crystal. See CRYSTAL.

5. Trase: usually lake-green, sometimes olive and pistachio green. Commonly in mass; rarely crystallized.

Cronstedt observes, that quartz in general, and especially its crystals, are very commonly supposed, when yet in their soft and dissolved state, to have included within them some vegetables; for instance, grass and moss. "This (says he) I cannot absolutely deny; but it deserves carefully to be examined, if that which is shown as a grass is not an asbestos, or a striated cockle; and the moss only branched varieties filled with earth, which, by their being ramose, bear a vegetable appearance. It is very common in agates, and makes them of less value than they otherwise would be. This is most generally the case with those stones which are shown as including vegetables: and for my own part, I have never been so fortunate as to meet with any others."

M. Magellan remarks, that quartz is one of the principal kinds of stone which contain metals. Some of the Hungarian veins consist entirely of it, and the gold is so minutely dispersed, that it cannot be discerned by the best microscopes before it is separated by pounding and washing. The width of the veins, some of which are half a fathom, and some still more, repay the trouble and expences, which the small quantity of gold would not otherwise counterbalance. Nature has not any where produced mountains of pure quartz; for though some rocks in Sweden are ranked among the quartzes, they are undoubtedly mixed with heterogeneous matters. Near Lauterberg upon the Hartz are veins of this stone from one to three fathoms wide, consisting of a loose sand, in which they find the copper ore in nests. In the Danish isle of Anhalt we meet with triangular quartz pebbles. There are likewise crystals of quartz having water enclosed in them; some fine pieces of this kind are to be met with in the imperial cabinet at Vienna, &c.

Rock crystals are generally found upon or among quartz, and are to be met with in all parts of the world. The greatest number are furnished to the European countries from mount Saint Gothard in Switzerland. Here large pieces, weighing from 5 to 800 pounds, were found at Grimselberg; one of 1200 pounds was found some years ago at Frisbach in the Valais; and a piece six feet long, four broad, and equally thick, was found in the island of Madagascar, a place where these natural productions are of the most extraordinary size and perfection.

When great quantities of quartz are continually agitated by the sea or river water, they are sometimes reduced to such very minute parts as to be easily carried away, suspended in the water; and there are sands of so minute a size as to measure less than the two or three hundredth part of an inch. These are called quick-sands. Immense tracts of land consist only of loose sands, particularly along the sea-shore in many parts of Europe. When sand is about as big as peas, it is called gravel; and when it is free from saline and heterogeneous particles, it is employed in making mortar, and for other economical purposes. That which is very pure serves for making flint-glass, with red calces of lead, and the proper alkaline flux; but when mixed with ferruginous-black sand, the glass assumes a greenish-black colour. "This (says M. Magellen) I have seen among the various specimens of glass made by Mr. E. Delaval, F. R. S. who produced a very fine transparent and colourless glass out of the same sand with which he had made some of that black glass, and this only by separating from it all the ferruginous mixture."

QUASSIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, gruinales. The calyx is pentaphyllous; there are five petals; the nectarium is pentaphyllous; there are from two to five seed-cases, standing asunder, and monospermous. There are three species, the amara, simaruba, and excelsa.

1. The quassia amara grows to the height of several feet, and sends off many strong branches. The wood is of a white colour and light; the bark is thin and grey; the leaves are placed alternately on the branches, and consist of two pair of opposite pinnæ, with an odd one at the end: the flowers are all hermaphrodite, of a bright red colour, and terminate the branches in long spikes. It is a native of South America, particularly of Surinam, and also of some of the West Indian islands. The root, bark, and wood, of this tree, have all places in the materia medica. The wood is most generally used, and is said to be a tonic, stomachic, antiseptic, and febrifuge.

2. The quassia simaruba is common in all the woody lands in Jamaica. It grows to a great height and considerable thickness. The trunks of the old trees are black and a little furrowed. Those of the young trees are smooth and grey, with here and there a broad yellow spot. The inside bark of the trunk and branches is white, fibrous, and tough. It tastes slightly bitter. The wood is hard, and useful for buildings. It splits freely, and makes excellent staves for sugar-hogsheads. It has no sensible bitter taste. The branches are alternate and spreading. The leaves are numerous and alternate. The flowers are of a yellow colour, and placed on spikes beautifully branched.

The fruit is of that kind called a drupa, and is ripe towards the end of May. It is of an oval shape, is black, smooth, and shining. The pulp is fleshy and soft; the taste nauseous and sweet. The nut is flattened, and on one side winged. The kernel is small, flat, and tastes sweet. The natural number of these drupæ is five on each common receptacle; but for the most part there are only two or three. The roots are thick, and run at a small depth under the surface of the ground to a considerable distance. The bark is rough, scaly, and warted. The inside when fresh is a full yellow, but when dry paler. It has but little smell. The taste is bitter, but not very disagreeable. This is the true cortex simarubæ of the shops. The shops are supplied with this bark from Guiana; but now we may have it from our own islands at a moderate expence.

Most authors who have written on the simaruba agree, that in fluxes it restores the lost tone of the intestines, allays their spasmodic motion, promotes the secretions by urine and perspiration, removes that lowness of spirits attending dysenteries, and disposes the patient to sleep; the gripes and tenesmus are taken off, and the stools changed to their natural colour and consistence. In a moderate dose it occasions no disturbance or uneasiness; but in a large dose it produces sickness at stomach and vomiting. Negroes are less affected by it than white people. Dr. Cullen, however, says, "We can perceive nothing in this bark but that of a simple bitter; the virtues ascribed to it in dysentery have not been confirmed by my experience, or that of the practitioners in this country; and leaving what others are said to have experienced to be further examined and considered by practitioners, I can only at present say, that my account of the effect of bitters will perhaps explain the virtues ascribed to simaruba. In dysentery I have found an infusion of camomile-flowers a more useful remedy."

3. The quassia excelsa, or polygama, was named by sir Joseph Banks, Dr. Solander, and Dr. Wright. It is very common in the woodlands of Jamaica, is beautiful, tall, and stately, some being 100 feet long, and 10 feet in circumference eight feet above the ground. The trunk is straight, smooth, and tapering, sending off its branches towards the top. The outside bark is pretty smooth, of a light grey or ash-colour, from various lichens. The bark of the roots is of a yellow cast, somewhat like the cortex simaruba. The wool is of a yellow colour, tough, but not very hard. It takes a good polish, and is used as flooring. The flowers are small, of a yellowish-green colour, with a very small calyx. The male or barren tree has flowers nearly similar to the hermaphrodite, but in it there are only the rudiments of a style. The fruit is a smooth black drupa, round-shaped, and of the size of a pea. Except the pulp of the fruit, every other part of this tree has an intensely bitter taste. In taste and virtues it is nearly equal to the quassia of Surinam. The happiest effects result from the use of this medicine in obstinate remitting fevers from marsh-miasmata, in agues which had resisted the use of Jesuits' bark, and in dysenteries of long standing. It is in daily practice in dropsies from debility, either in simple infusions or tincture by itself, or joined with aromatics and chalybeates. Dr. Drummond, an eminent physician in Jamaica, prescribes it with great success in the above cases, as well as in amenorrhœa, chlorosis, dyspepsia, and in that species of pica called dirt-eating, so fatal to a number of negroes.

The bark of the quassia polygama, but especially the wood, is intensely bitter. They may both be used in various forms. In certain cases of dropsy, aromatics and preparations are joined to it, also in amenorrhœa ad chlorosis; and in worm fevers, the cabbage-bark, or other vegetable anthelmintics.

Quassia, in chemistry. Many vegetable substances have an intensely bitter taste, and on that account are employed in medicine, by brewers, &c. This is the case with the wood of the quassia amara and excelsa, the common quassia of the shops; with the roots of the gentiana lutea, common gentian; the leaves of the humulus lupulus or hop; the bark and wood of the spartium scoparium, or common broom; the flowers and leaves of the anthemis nobilis or chamomile; and many other substances. These bodies owe their bitter taste to the presence of a peculiar vegetable substance differing from every other, which may be distinguished by the name of the bitter principle.

No chemical examination of this substance has been hitherto published; nor indeed are we in possession of any method of separating it from other bodies, or of ascertaining its presence. At the same time it cannot be doubted that it possesses peculiar characters; and its action on the animal economy renders it an object of importance.

1. When water is digested over quassia for some time, it acquires an intensely bitter taste and a yellow colour, but no smell. When water thus impregnated is evaporated to dryness in a low heat, it leaves a brownish-yellow substance, which retains a certain degree of transparency. It continues ductile for some time, but at last becomes brittle. This substance we might consider as the bitter principle in a state of purity. If it contains any foreign body it must be in a very minute proportion. This substance is found to possess the following properties: 1. Its taste is intensely bitter. Colour brownish-yellow. 2. When heated, softens, and swells, and blackens; then burns away without flaming much, and leaves a small quantity of ashes. 3. Very soluble in water and in alcohol. 4. Does not alter the colour of infusion of litmus. 5. Lime water, barytes water, and strontian water, occasion no precipitate. Neither is any precipitate thrown down by silicated potass, aluminated potass, or sulphat of magnesia. 6. The alkalies occasion no change in the diluted solution of the bitter principle. 7. Oxalat of ammonia occasions no precipitate. 8. Nitrat of silver renders the solution muddy, and a very soft flaky yellow precipitate falls slowly to the bottom. 9. Neither corrosive sublimate nor nitrat of mercury occasions any precipitate. 10. Nitrat of copper, and the ammoniacal solution of copper, produce no change; but muriat of copper gives the white precipitate, which falls when this liquid salt is dropt into water. 11. Sulphat and oxymuriat of iron occasion no change. 12. Muriat of tin renders the solution muddy, but occasions no precipitate, unless the solution is concentrated; in that case a copious precipitate falls. 13. Acetat of lead occasions a very copious white precipitate. But the nitrat of lead produces no change. 14. Muriat of zinc occasions no change. 15. Nitrat of bismuth produces no change, though when the salt is dropt into pure water a copious white precipitate appears. 16. Tartar emetic produces no change; but when the muriat of antimony is used, the white precipitate ap-

pears, which always falls when this salt is dropt into pure water. 17. Muriat and arseniat of cobalt occasion no change. 18. Arseniat of potass produces no effect. 19. Tincture of nutgalls, infusion of nutgalls, gallic acid, occasion no effect.

These properties are sufficient to convince us that the bitter principle is a substance differing considerably from all the other vegetable principles. The little effect of the different reagents is remarkable. Nitrat of silver and acetat of lead are the only two bodies which throw it down. This precipitation cannot be ascribed to the presence of muriatic acid; for if muriatic acid was present, nitrat of lead would also be thrown down. Besides, the flakes introduced by nitrat of silver are too light, and indeed have no resemblance whatever to muriat of silver. The precipitate by acetat of lead is very copious. This salt is therefore the best substance for detecting the presence of the bitter principle, when we are certain that no other substance is present which throws down lead.

QUEEN, a woman who holds a crown singly. The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort.

A queen-consort is inferior to the king, and is really his subject, though, as the king's wife, she has several prerogatives above other women. Though an alien, she may purchase lands in fee-simple, without either naturalization or denization. She may present to a benefice. She shall not be amerced if she is nonsuited in any action; and may not be impleaded till first petitioned. To conspire her death, or violate her chastity, is high treason. She has an antient peculiar revenue called queen-gold; besides a very large dower, with a royal court, and officers of her own. No person here must marry a queen dowager without the licence of the succeeding king, on pain of forfeiting his lands and goods; but though she marry any of the nobility, or even one under that degree, she does not lose her dignity.

QUERCUS, the *oak-tree*, a genus of the polyandria order, in the monœcia class of plants, and in the natural method ranking under the 50th order, amentaceæ. The calyx is nearly quinquefid; there is no corolla; the stamina are from five to ten in number. The female calyx is monophyllous, very entire, and scabrous. There is no corolla; the styles are from two to five; and there is an ovate seed.

There are 26 species; the most remarkable are: 1. The robur, or common English oak, from about 60 or 70 to 100 feet high, with a prodigious large trunk and spreading head. There is a variety having the leaves finely striped with white. This species grows in great abundance all over England, in woods, forest, and hedge-rows, and is supposed to continue its growth many centuries. 2. The prinus, or chesnut-leaved American oak, grows 50 or 60 feet high; having large oblong-oval smooth leaves, pointed both ways, the edges sinuated-serrated, with the sinuses uniformly round. 3. The phellos, or willow-leaved American oak, grows 40 or 50 feet high, having long, narrow, smooth, entire leaves, like those of the willow. There is a variety called the dwarf willow-leaved oak. 4. The alba, or white Virginian oak, grows 30 or 40 feet high, having a whitish bark, with long obliquely pinnatifid light-green leaves, the sinuses and angles obtuse. 5. The nigra, or black Virginian oak, grows 30 or 40 feet high, having a dark-coloured bark, large wedge-shaped slightly-trilobated leaves. 6. The rubra, or red Virginian oak, grows about 60 feet high, having a dark-greyish bark, long obtusely-sinuated leaves, with the sinuses terminated by bristly points, and sometimes red spotted veins, but generally dying in autumn to a reddish colour, remaining on the trees late in the season. 7. The esculus of Pliny, or cut-leaved Italian oak, grows about 30 feet high, having a purplish bark, oblong deeply-sinuated smooth leaves, and long slender close-sitting acorns in very large cups. 8. Ægilops, or large prickly-cupped Spanish oak, grows 70 or 80 feet high, or more, with a very large trunk, and widely spreading head, having a whitish bark, large oblong-oval deeply-serrated smooth leaves, the serratures bowed backward, and large acorns placed in singularly large prickly-cups. This is a noble species, almost equal in growth to our common English oak. 9. Cerris, or smaller prickly-cupped Spanish oak, grows 30 or 40 feet high, and has oblong lyre-shaped pinnatifid transversely-jagged leaves, downy underneath, and small acorns placed in prickly cups. 10. The ilex, or common evergreen oak, grows 40 or 50 feet high, having a smooth bark, oval and oblong undivided serrated petiolated leaves, downy and whitish underneath. The varieties are, broad-leaved, narrow-leaved, and sometimes both sorts, and other different-shaped leaves on the same tree; also sometimes with sawed and prickly leaves. 11. The gramuntia, or Montpelier holly-leaved evergreen oak, grows 40 or 50 feet high; and has oblong-oval, close-sitting, sinuated, spinous leaves, downy underneath, bearing a resemblance to the leaves of holly. 12. The suber, or cork-tree, grows 30 or 40 feet high, having a thick, rough, fungous, cleft bark, and oblong-oval, undivided, serrated leaves, downy underneath. This species furnishes that useful material cork, it being the bark of the tree; which becoming of a thick fungous nature, under which, at the same time, is formed a new bark, and the old being detached for use, the tree still lives, and the succeeding young bark becomes also of the same thick spongy nature in six or seven years, fit for barking, having likewise another fresh bark forming under it, becoming cork like the others in the like period of time: and in this manner these trees wonderfully furnish the cork for use. The tree grows in great plenty in Spain and Portugal, and from these countries we receive the cork. The Spaniards burn it, to make that kind of light black we call Spanish black, used by painters. Cups made of cork are said to be good for hectical persons to drink out of. The Egyptians made coffins of cork, which being lined with a resinous composition, preserved dead bodies uncorrupted. The Spaniards line stone walls with it, which not only renders them very warm, but corrects the moisture of the air. 13. The coccifera, scarlet, or kermes oak, grows but 14 or 15 feet high, branching all the way, and of bushy growth, with large oval, undivided, indented, spinous leaves, and producing small glandular excrescences, called kermes, or scarlet grain, used by the dyers. The small scarlet glands found in this tree are the effect of certain insects depositing their eggs betwixt the bark of the branches and leaves, causing an extravasation of the sap, and forming the excrescence or substance in question, which being dried is the kermes or scarlet pastel. 14. The Molucca, Moluccan oak, commonly called American live oak, grows about 40 feet high, having oval, spear-shaped, smooth, entire leaves, and small, oblong, eatable acorns.

All the above produce flowers annually in the spring, about April or May, of a yellowish colour, but make no ornamental appearance, and are males and females separated in the same tree, the males being in loose amentums, and the females sitting close to the buds in thick leathery hemispherical calyxes, succeeded by the fruit or acorns.

The English oak claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood. Every possessor of considerable estates ought therefore to be particularly assiduous in raising woods of them; which is effected by sowing the acorns either in a nursery and the plants transplanted where they are to remain, or sown at once in the places where they are always to stand. All the sorts will prosper in any middling soil and open situation, though in a loamy soil they are generally more prosperous; however, there are but few soils in which oaks will not grow; they will even thrive tolerably in gravelly, sandy, and clayey land, as may be observed in many parts of this country of the common oak.

The oak is remarkable for its slowness of growth, bulk, and longevity. It has been remarked that the trunk has attained to the size only of fourteen inches in diameter, and some to twenty, in the space of fourscore years. As to bulk, we have an account of an oak belonging to lord Powis, growing in Broomfield-wood, near Ludlow in Shropshire, in the year 1764, the trunk of which measured 68 feet in girth, 23 in length, and which, reckoning 90 feet for the larger branches, contained in the whole 1455 feet of timber, round measure, or 29 loads and five feet, at 50 feet to a load.

In the opinion of many, the Cowthorp oak near Wetherby, in Yorkshire, is the father of the forest. Dr. Hunter, in his edition of Evelyn, has given an engraving of it. Within three feet of the surface, he says, it measures 16 yards, and close to the ground 26. In 1776, though in a ruinous condition, it was 85 feet high, and its principal limb extended 16 yards from the bole. The foliage was very thin. If this measurement was taken as the dimensions of the real stem, the size of this tree would be enormous; but, like most very large trees, its stem is short, spreading wide at the base, the roots rising above the ground like buttresses to the trunk, which is similar not to a cylinder but to the frustum of a cone. Mr. Marsham says, "I found it in 1768, at four feet, 40 feet 6 inches; at five feet, 36 feet 6 inches; and at six feet, 32 feet 1 inch." In the principal dimensions then, the size of the stem, it is exceeded by the Bentley oak, of which the same writer gives the following account: "In 1759 the oak in Holt-forest, near Bentley, was at seven feet, 34 feet. There is a large excrescence at five and six feet that would render the measure unfair. In 1778 this tree was increased half an inch in 10 years. It does not appear to be hollow, but by the trifling increase I conclude it not sound.". These dimensions, however, are exceeded by those of the Boddington oak. It grows in a piece of rich grass land, called the old orchard ground, belonging to Boddington manor-farm, lying near the turnpike-road between Cheltenham and Tewksbury, in the vale of Gloucester. The stem is remarkably collected at the root, the sides of its trunk being much more upright than those of large trees in general; and yet its circumference at the ground is about 20 paces; measuring with a two-foot rule, it is more than 18 yards. At three feet high it is 42 feet, and where smallest, *i. e.* from five to six feet high, it is 36 feet. At six feet it swells out larger, and forms an enormous head, which has been furnished with huge, and probably extensive, arms. But time and the fury of the wind have robbed it of much of its grandeur, and the greatest extent of arm in 1783 was eight yards from the stem.

In the Gentleman's Magazine for May 1794, we have an account of an oak-tree growing in Penshurst-park in Kent, together with an engraving. It is called the bear or bare oak, from being supposed to resemble that which Camden thought gave name to the county of Berkshire. The dimensions of the tree are these:

	Feet.	Inches.
Girth close to the ground	35	6
Ditto one foot from ditto	27	6
Ditto five feet from ditto	24	0
Height taken by shadow	73	0
Girth of lowest, but not largest limb	6	9

With respect to longevity, Linnæus gives account of an oak 260 years old; but we have had traditions of some in England (how far to be depended upon we know not) that have attained to more than double that age. Mr. Marsham, in a letter to Thomas Beevor, Esq. Bath Papers, vol. i. p. 79, makes some very ingenious calculations on the age of trees, and concludes from the increase of the Bentley oak, &c. that the Fortworth chesnut is 1100 years old.

Besides the grand purposes to which the timber is applied in navigation and architecture, and the bark in tanning of leather, there are other uses of less consequence, to which the different parts of this tree have been referred. The highlanders use the bark to dye their yarn of a brown colour, or, mixed with copperas, of a black colour. Oak saw-dust is also a principal ingredient in dyeing drabs, especially in fustian. The acorns are a good food to fatten swine and turkeys; and after the severe winter of the year 1709, the poor people in France were miserably constrained to eat them themselves. There are, however, acorns produced from another species of oak, which are eaten to this day in Spain and Greece, with as much pleasure as chesnuts, without the dreadful compulsion of hunger.

Quercus marina, the sea oak. See Fucus.

QUERIA, a genus of the trigynia order, in the triandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is pentaphyllous; there is no corolla; the capsule is unilocular, and trivalved, with one seed. There are three species, viz. hispanica, canadensis, and trichotoma.

QUICK, or Quickset hedge, among gardeners, denotes all live hedges, of whatsoever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, or cratægus oxyacantha, under which name these young plants, or sets, are sold by the nursery-gardeners, who raise them for sale. See Cratægus.

Quick-silver. See Mercury.

QUILTING, a method of sewing two pieces of silk, linen, or stuff, on each other, with wool or cotton between them; by working them all over in the form of chequer or diamond work, or in flowers. The same name is also given to the stuff so worked.

QUINCE. See Pyrus.

QUINCHAMALIA, a genus of the pentandria monogynia class and order. The calyx is inferior, five-toothed; corolla tubular, superior; anth. sessile; seed one. There is one species, a herb of Chili.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five-twelfth parts of another, but particularly of the as.

Quincunx order, in gardening, a plantation of trees, disposed originally in a square, and consisting of five trees, one at each corner, and a fifth in the middle; or a quincunx is the figure of a plantation of trees, disposed in several rows, both length and breadthwise, in such a manner, that the first tree in the second row commences in the centre of the square formed by the two first trees in the first row, and the two first in the third, resembling the figure of the five at cards.

QUINDECAGON, in geometry, a plane figure with fifteen sides and 15 angles, which, if the sides are all equal, is termed a regular quindecagon, and irregular when otherwise.

The side of a regular quindecagon inscribed in a circle is equal in power to the half-difference between the side of the equilateral triangle, and the side of the pentagon inscribed in the same circle; also the difference of the perpendiculars let fall on both sides, taken together.

QUINQUINA. See Cinchona, and Pharmacy.

QUINTILE, in astronomy, an aspect of the planets when they are 72 degrees distant from one another, or a fifth part of the zodiac.

QUIRE of paper, a quantity of 24 or 25 sheets.

QUISQUALIS, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. The calyx is quinquefid and filiform; the petals five; the fruit is a quinque-angular plum. There is only one species, viz. Indica, a shrub of the East Indies.

QUI TAM, in law, is where an action is brought, or an information exhibited, against a person, on a penal statute, at the suit of the king and the party or informer, when the penalty for breach of the statute is directed to be divided between them; in that case, the informer prosecutes as well for the king as himself.

QUIT-CLAIM, in law, signifies a release of any action that one person has against another. It signifies also a quitting a claim or title to lands, &c.

Quit-rent, in law, a small rent that is payable by the tenants of most manors, whereby the tenant goes quit and free from all other services. Antiently this payment was called white-rent, on account that it was paid in silver coin, and to distinguish it from rent-corn.

QUOIN, or Coin, on board a ship, a wedge fastened on the deck close to the breech of the carriage of a gun, to keep it firm up to the ship's side.

QUOITS, a kind of exercise or game known among the antients under the name discus.

QUO MINUS, is a writ which issues out of the court of exchequer to the king's farmer or debtor, for debt, trespass, &c. Though this writ was formerly granted only to the king's tenants or debtors, the practice now is become general for the plaintiff to surmise, that by the wrong the defendant does him, he is the less able to satisfy his debt to the king, by which means jurisdiction is given to the court of exchequer to determine the cause. This writ is to take the body of the defendant in like manner as the capias in the common pleas, and the writ of latitat in the king's bench.

Quo-warranto, in law, a writ which lies against a person or corporation that usurps any franchise or liberty against the king; as to have a fair, market, or the like, in order to oblige the usurper to shew by what right and title he holds or claims such franchise. This writ also lies for mis-user or non-user of privileges granted. The attorney-general may exhibit a quo-warranto in the crown-office against any particular persons, or bodies politic or corporate, who use any franchise or privilege without having a legal grant or prescription for the same; and a judgment obtained upon it is final, as being a writ of right.

R.

R, the seventeenth letter of our alphabet. In the notes of the antients, R. or RO. signifies Roma; R. C. Romana civitas; R. G. C. rei gerendæ causa; R. F. E. D. recte factum et dictum; R. G. F. regis filius; R. P. res publica, or Romani principes; and R.R.R.F.F.F. res Romana ruet ferro, fame, flamma.

Used as a numeral, R antiently stood for eighty, and with a dash over it, thus R̄, for 80,000; but the Greek r, or ϱ, signified 100.

In the prescriptions of physicians, R or ℞ stands for recipe, i. e. take.

RABBETING, in carpentry, the planing or cutting of channels or grooves in boards. In ship-carpentry, it signifies the letting-in of the planks of the ship into the keel; which, in the rake and run of a ship, is hollowed away, that the planks may join the closer.

RABBIT. See LEPUS.

RACHITIS. See MEDICINE.

RACK. See ARRACK.

RACKOON. See URSUS.

RADIAL CURVES, are curves of the spiral kind, whose ordinates, if they may be so called, all terminate in the centre of the including circle, appearing like radii of that circle, whence the name.

RADIALIS, or RADIÆUS. See ANATOMY.

RADIANT. See HERALDRY.

RADIATED FLOWERS. See BOTANY.

RADIATION, the act of a body emitting or diffusing rays of light all round, as from a centre.

RADICLE. See PLANTS, *physiology of*, BOTANY, and GERMINATION.

RADIUS, in geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference. See CIRCLE, and GEOMETRY.

RADIUS. See ANATOMY.

RAFT, a sort of float, formed by an assemblage of various planks or pieces of timber fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road than if they were separate. The timber and plank with which merchant-ships are laden, in the different parts of the Baltic Sea, are attached together in this manner, in order to float them off to the shipping.

RAFTERS, in building, are pieces of timber, which standing by pairs on the raising-piece, meet in an angle at the top, and form the roof of a building. It is a rule in building, that no rafters should stand farther than 12 inches from one another: and as to their sizes or scantlings, it is provided by act of parliament, that principal rafters, from 12 feet six inches to 14 feet six inches long, shall be five inches broad at the top, and eight at the bottom, and six inches thick. Those from 14 feet six inches to 18 feet six inches long, to be nine inches broad at the foot, seven inches at the top, and seven inches thick; and those from 18 feet six inches, to 21 feet six inches long, to be 10 inches broad at the foot, eight at the top, and eight thick. Single rafters, eight feet in length, must have four inches and a half, and three inches three quarters, in their square. Those of nine feet long, must be five and four inches square.

Principal rafters should be nearly as thick at the bottom as the beam, and should diminish in their length one-fifth or one-sixth of their breadth; the king-posts should be as thick as the principal rafters; and their breadth according to the size of those that are intended to be let into them, the middle part being left somewhat broader than the thickness.

RAG WORT. See SENECIS.

RAGG, *rowley*, a genus of stones belonging to the siliceous class. It is of a dusky or dark-grey colour, with many small shining crystals, having a granular texture, and acquiring an ochry crust by exposure to the air. The specific gravity is 2.748. It becomes magnetic by being heated in an open fire. In a strong fire it melts without addition, but with more difficulty than basaltes. It was analysed by Dr. Withering, who found that 100 parts of it contain 47.5 of siliceous earth, 32.5 of argil, and 20 of iron.

RAJA, *ray*, a genus of fishes of the class amphibia, and of the order nantes. The generic character is, mouth situated beneath the head, transverse, beset with teeth; spiracles beneath, five on each side the neck; body in most species sub-rhomboidal.

This genus, of which there are 19 species, is distinguished by the remarkable breadth and thinness of the body, the pectoral fins appearing like a continuation of the sides themselves, being covered with the common skin. Their rays are cartilaginous, straight, and furnished with numerous swellings or knots; the teeth are very numerous, small, and placed in ranges over the lips or edges of the mouth; the eyes are furnished with a nictitating membrane or skin, which can at pleasure be drawn over them like an eyelid; and at some distance above the eyes are situated the nostrils, each appearing like a large and somewhat semilunar opening edged with a reticulated skin, and furnished internally with a great many laminated processes divided by a middle partition; they are guarded by an exterior valve: behind the eyes are also a pair of holes communicating with the mouth and gills: these latter, taken together, present a vast extent of surface: the young are contained in oblong square capsules, with lengthened corners, and are discharged at distant intervals, the young animal gradually liberating itself from its confinement, and adhering for some time by the umbilical vessels. The rays in general feed on the smaller kind of crabs, testacea, marine insects, and fishes. They are constant inhabitants of the sea, lying concealed during part of the winter among the mud or sand, from which they occasionally emerge and swim to unlimited distances.

1. Raja batis, of a rhomboid shape. The skate is one of the largest of the European rays, sometimes weighing from one to two hundred pounds, and even, according to some accounts, not less than three. Its general colour on the upper parts is a pale cinereous brown, varied with several darker or blackish undulations; the under part is white, marked with numerous, distant, black specks; in the male, the pectoral fins are beset towards their tips or edges with numerous small spines; on each side the tail, at some distance from the base, is a sharp spine; several very strong ones run down the back of the tail, and in some specimens a row of smaller ones is visible on each side. As an edible fish, the skate is considered as one of the best of its tribe, and is an established article in the European markets, being found in great plenty in the adjoining seas, where it usually frequents the shores in the manner of flat fish. It breeds in the month of March and April, and deposits its ova from May to September. We are informed by Mr. Willughby, that a skate of 200 pounds weight was sold in the fish-market at Cambridge to the cook of St. John's college in that university, and was found sufficient to dine the whole society, consisting of more than 120 persons. In October the skate is usually poor and thin, begins to improve in November, and grows gradually better till May, when it is considered as in its highest perfection.

2. Raja clavata, the thornback, grows to a very considerable size, though rarely equal in magnitude to the skate. In its general appearance it resembles that fish, but is somewhat broader in proportion, and is easily distinguished from the skate by the very strong curved spines with which its upper surface is covered: these are most conspicuous down the middle and on each side of the back, where four or six, of much larger size than the rest, are generally seen; the remaining parts being furnished with many scattered spines of smaller size, intermixed with still more minute ones, and the whole skin is of a rough or shagreen-like surface; the back is marked with an uncertain number of pale or whitish round spots, of different sizes, and which are commonly surrounded with a blackish or dark-coloured edge: these spots are said to be caused by the shedding of the spines at different intervals; along the middle of the back runs a single row of strong spines, continued to the tip of the tail; and it often happens that there are three or even five rows of spines on this part: the colour

of the skin is a brownish grey, with irregular blackish or dusky variegations; the under part is white, with a slight cast of flesh-colour; and about the middle of the body, as well as on the fins, are disposed several spines, similar to those on the upper side, but less strong: the cartilage dividing the upper and lower portions of the body, is in this species remarkably conspicuous; but since a similar appearance exists in several other species, it cannot be of much importance in the specific character.

The thornback is an inhabitant of the Mediterranean and other seas, and is in some esteem as a food, though not equal to the skate in goodness.

3. Raja chagrinea, shagreen ray. Body less broad in proportion than in most others of this division; snout long and pointed, and furnished with two rows of spines; several others are placed in a semicircle towards the eyes, of which the iris is sapphire-coloured; both sides of the tail are armed with numerous smaller ones; the whole upper surface of the animal is roughened by numerous small granules like those on the skin of some of the shark-tribe, and particularly of the great dog-shark, of the skin of which is prepared the substance known by the name of shagreen; colour above cinereous brown, beneath white. Native of the European seas.

4. Raja pastinaca, sting ray, with slender tail, generally armed with a spine. Shape subrhomboidal, but somewhat approaching to ovate, the pectoral fins being less pointed than in some of this division; snout pointed; body more convex than in the preceding rays; colour of the whole animal above yellowish-olive, with the back darkest, and approaching, in some specimens, to a blueish brown; beneath whitish; tail without fin, of considerable length, very thick at the base, and gradually tapering to the extremity, which is very slender; near the middle it is armed, on the upper part, with a very long, flattened, and very sharp-pointed bone or spine, finely serrated in a reversed direction on both sides; with this the animal is capable of inflicting very severe wounds on such as incautiously attempt to handle it; and it answers the purpose both of an offensive and defensive weapon: it is annually cast, and as it frequently happens that the new spine has arrived at a considerable size before the old one has been cast, the animal is occasionally found with two, in which state it has been sometimes erroneously considered as a distinct species. This fish is said not to grow to so large a size as many others of the genus: it is an inhabitant of the Mediterranean, Atlantic, and Indian seas, and is numbered among the edible rays. On account of the danger attending the wounds inflicted by the spine, it is usual with the fishermen to cut off the tail as soon as the fish is taken; and it is said to be illegal in France, and some other countries, to sell the animal with the tail still adhering. It is hardly necessary to observe, that the spine is perfectly void of any venomous quality, though formerly supposed to contain a most active poison; and that the effects sometimes produced by it are entirely those arising from deep puncture and laceration, which, if taking place in a tendinous part, or among the larger nerves and blood-vessels, have often proved fatal.

The general habits of the animal are similar to those of the rest of the genus, often lying flat and in ambuscade on the soft mud at the bottom of the shores which it frequents, and seizing its prey by surprise, and at other times pursuing it through the depths of the ocean.

5. Raja aquila, eagle ray. This species grows to a very great size, sometimes measuring ten, twelve, or even fifteen feet in length.

6. Raja sephen, pearled ray. Shape subrhomboid; the upper part of the body, measured from the tips of the pectoral fins, which are obtuse, forming a half-rhomb; the lower part, from the tips of the pectoral fins to the tail, forming a half-circle; snout small and slightly pointed; ventral fins rather small and rounded; tail more than twice the length of the body, gradually tapering to a fine point, furnished beneath the middle part with a shallow fin running to a considerable distance, and above with a strong and sharp spine, as in the sting ray and many others, and sometimes two spines are found instead of one; back, from between the eyes to some distance beyond the base of the tail, covered with pretty close-set tubercles or granules, three of which, in the middle of the back, are far larger than the rest, and resemble three pearls disposed in a longitudinal direction on that part: colour of the whole animal deep cinereous-brown above, and reddish white beneath: grows to a large size, sometimes measuring eleven feet from the snout to the end of the tail. Native of the Red Sea.

It is from the skin of this species, according to Cepede, that the beautiful substance called galuchat by the French is prepared; and which being coloured with blue, green, or red, according to the fancy of the artist, and afterwards polished, is so frequently used for various kinds of cases, telescope-tubes, &c. For this purpose the smaller or younger specimens are preferred; the tubercles in the more advanced or full-grown animals being too large for the uses above-mentioned.

7. Raja diabolus, demon ray, with bilobate front. This highly singular animal, in point of general shape, is allied to the eagle ray, but with a much greater extent of pectoral fins, appearing extremely broad in proportion to its length; the head, which is of moderate size, is straight or rectilinear in front, each side projecting into a vertically flattened and slightly pointed lobe or wattle, of nearly two feet in length, and giving somewhat the appearance of a pair of horns; the pectoral fins are of a subtriangular figure, curving downwards on each side, and terminating in a point; the back is very slightly elevated into a somewhat pyramidal form; and at its lower part is situated the dorsal fin, which is of a lengthened shape, and inclines backwards. This species is an inhabitant of the Mediterranean, Atlantic, and Indian seas. It is said to be chiefly observed about the Azores, where it is known by the name of mobular.

8. Raja torpedo, of a rounded shape. The torpedo has been celebrated both by antients and moderns for its wonderful faculty of causing a sudden numbness or painful sensation in the limbs of those who touch or handle it. This power the antients, unacquainted with the theory of electricity, were contented to admire, without attempting to explain; and, as is usual in similar cases, magnified it into an effect little short of what is commonly ascribed to enchantment. Thus we are told by Oppian, that the torpedo, conscious of his latent faculty, when caught by a hook, exerts it in such a manner, that, passing along the line and rod, it benumbs the astonished fisherman, and suddenly reduces him to a state of helpless stupefaction. See ELECTRICITY, and GALVANISM.

The body of the torpedo is of a somewhat circular form, perfectly smooth, slightly convex above, and marked along each side of the spine by several small pores or foramina; the colour of the upper surface is usually a pale reddish-brown, sometimes marked by five large, equidistant, circular, dusky spots with paler centres; the under surface is whitish, or flesh-coloured. The torpedo, however, is observed to vary considerably in the cast and intensity of its colours. The general length of the torpedo seems to be about eighteen inches or two feet, but it is occasionally found of far larger dimensions; specimens having been taken on our own coasts of the weight of fifty, sixty, and even eighty pounds.

The torpedo is an inhabitant of most seas, but seems to arrive at a larger size in the Mediterranean than elsewhere. It is generally taken with the trawl, but has been sometimes known to take a bait. It commonly lies in water of about forty fathoms depth, in company with others of this genus. It preys on smaller fish, and according to Mr. Pennant, a surmullet and a plaise have been found in the stomach of two of them: the surmullet, as Mr. Pennant well observes, is a fish of that swiftness, that it would be impossible for the torpedo to take it by pursuit; we must therefore suppose that it stupefies its prey by exerting its electric faculty. The torpedo often inhabits sandy places, burying itself superficially, by flinging the sand over it, by a quick flapping of all the extremities. It is in this situation that it gives its most forcible shock, which is said to throw down the astonished passenger that inadvertently treads on the animal.

The torpedo, with respect to its general anatomy, does not materially differ from the rest of the ray tribe, except in its electric or galvanic organs.

It appears that the electric organs of the torpedo constitute a pair of galvanic batteries, disposed in the form of perpendicular hexagonal columns. In the gymnotus electricus, on the contrary, the galvanic battery is disposed lengthwise on the lower part of the animal.

Spallanzani informs us, that some few minutes before the torpedo expires, the shocks which it communicates, instead of being given at distant intervals, take place in quick succession, like the pulsations of the heart: they are weak, indeed, but perfectly perceptible to the hand when laid on the fish at this juncture, and resemble very small electric shocks. In the space of seven minutes, no less than 360 of these small shocks were perceived. Spallanzani also assures us of another highly curious fact, which he had occasion to verify from his own experience, viz. that the young torpedo can not only exercise its electric faculty as soon as born, but even while it is yet a fœtus in the body of the parent animal. This fact was ascertained by Spallanzani on dissecting a torpedo in a pregnant state, and which contained in its ovarium several roundish eggs of different sizes, and also two perfectly formed fœtuses, which, when tried in the usual manner, communicated a very sensible electric shock, this was still more perceptible when the little animals were insulated by being placed on a plate of glass.

The electricity of the torpedo is altogether voluntary, and sometimes, if the animal is not irritated, it may be touched or even handled without being provoked to exert its electric influence.

9. Raja rhinobatos, of a lengthened shape. This remarkable species seems from its habit to connect in some degree the genera of raja and squalus, the body being much longer than in the preceding kinds of ray: the snout is lengthened, but not very sharp; and the body, which is moderately convex above, and flat beneath, gradually tapers from the shoulders to the tail, which is furnished above with two fins, of an oblong shape, and situated at a considerable distance from each other; the tip of the tail is also dilated into an oblong fin. The colour of the whole animal is a dull earthy-brown, paler beneath, and the skin is every where roughened by minute tubercles. This fish is said to grow to the length of about four feet, and is a native of the European seas. It is observed to be more frequent about the coasts of Naples than elsewhere.

RAJANIA, a genus of the hexandria order, in the diœcia class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. The male calyx is sexpartite; there is no corolla. The female calyx as in the male, without any corolla; there are three styles; the fruit is roundish, with an oblique wing, inferior. There are seven species, climbing plants of the West Indies.

RAIL, in ornithology. See RALLUS.

RAIN. See METEOROLOGY.

RAINBOW. See OPTICS.

RAISING-PIECES, in architecture, are pieces that lie under the beams, and over the posts or puncheons.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant; but the latter have a latent acidity with the sweetness, that renders them much less agreeable.

The common way of drying grapes for raisins is, to tie two or three bunches of them together while yet on the vine, and dip them into a hot lixivium of wood-ashes with a little of the oil of olives in it. This disposes them to shrink and wrinkle; and after this they are left on the vine three or four days separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. The finest and best raisins are those called in some places Damascus and Jube raisins; which are distinguished from the others by their size and figures: these are flat and wrinkled on the surface, soft and juicy within, and near an inch long; and when fresh and growing on the bunch, are of the size and shape of a large olive.

The raisins of the sun, and jar-raisins, are all dried by the heat of the sun; and these are the sorts used in medicine.

RAKE *of a ship*, is all that part of her hull which hangs over both ends of her keel. That which is before is called the fore-rake, or rake-forward; and that part which is at the setting on of the stern-post, is called the rake-aft or afterward.

RALLUS, the *rail*, in ornithology, a genus belonging to the order of grallæ. The beak is thickest at the base, compressed, equal, acute, and somewhat sharp on the back near the point; the nostrils are oval; the feet have four toes, without any web; and the body is compressed. Mr. Latham, in his Index Ornithologicus, enumerates 24 species, besides some varieties. They are chiefly distinguished by their colour. "These birds (says Buffon) constitute a large family, and their habits are different from those of the other shore-birds which reside on sands and gravel. The rails, on the contrary, inhabit only the slimy margins of pools and rivers, especially low grounds covered with flags and other large marsh-plants. This mode of living is habitual, and common to all the species of water-rails. The land-rail frequents meadows; and from the disagreeable cry, or rather rattling in the throat, of this bird, is derived the generic name. In all the rails, the body is slender, and shrunk at the sides; the tail extremely short; the head small; the bill like that of the gallinaceous kind, though much longer, and not so thick; a portion of the leg above the knee is bare; the three fore-toes without membranes, and very long; they do not, like other birds, draw their feet under their belly in flying, but allow them to hang down; their wings are small, and very concave, and their flight is short. They seem to be more diffused than varied; and nature has produced or transported them over the most distant lands. Captain Cook found them at the Straits of Magellan, in different islands of the southern hemisphere, at Anamoka, at Tanna, and at the isle of Norfolk. In the Society Islands there are two species of rails; a little black-spotted one (pooanée), and a little red-eyed one (moiho). It appears that the two acolins of Fernandez, which he denominates water-quails, are of a species of rails peculiar to the great lake of Mexico. The colins, which might be confounded with these, are a kind of partridges." The principal species are,

1. The aquaticus, or water-rail, a bird of a long slender body, with short concave wings. It delights less in flying than running, which it does very swiftly along the edges of brooks covered with bushes; as it runs, it every now and then flirts up its tail, and in flying hangs down its legs, actions it has in common with the water-hen. Its weight is four ounces and a half. The length to the end of the tail is 12 inches; the breadth 16. The bill is slender, slightly incurvated, an inch and three quarters long; the head, hind part of the neck, the back, and coverts of the wings and tail, are black, edged with olive-brown; the throat, breast, and upper part of the belly, are ash-coloured; the sides under the wings as far as the rump, finely varied with black and white bars. The tail is very short, and consists of twelve black feathers. "Water-rails (says Buffon) are seen near the perennial fountains during the greatest part of the winter, yet like the land-rails they have their regular migrations. They pass Malta in the spring and autumn. The viscount de Querhoent saw some fifty leagues off the coasts of Portugal on the 17th of April. They were so fatigued, that they suffered themselves to be caught by the hand. Gmelin found these birds in the countries watered by the Don. Belon calls them black rails, and says they are every where known, and that the species is more numerous than the red rail or land-rail. The flesh of the water-rail is not so delicate as that of the land-rail, and has even a marshy taste, nearly like that of the gallinule. It continues the whole year in England."

2. The porzana, or gallinule, is not very frequent in Great Britain, and is said to be migratory. It inhabits the sides of small streams, concealing itself among the bushes. Its length is nine inches; its breadth fifteen; it weighs four ounces five drachms. The head is brown, spotted with black; the neck a deep olive, spotted with white; the feathers of the back are black next their shafts, then olive-coloured, and edged with white: the scapulars are olive, finely marked with two small white spots on each web; the legs of a yellowish green. "Its habits (says Buffon) wild, its instinct stupid, the porzana is unsusceptible of education, nor is even capable of being tamed. We raised one, however, which lived a whole summer on crumbs of bread and hemp-seed: when by itself, it kept constantly in a large bowl of water; but if a person entered the closet where it was shut, it ran to conceal itself in a small dark corner, without venting cries or murmurs. In the state of liberty, however, it has a sharp piercing voice, much like the scream of a young bird of prey; and though it has no propensity to society, as soon as one cries, another repeats the sound, which is thus conveyed through all the rest in the district. Like all the rails, it is so obstinately averse to rise, that the sportsman often seizes it with his hand, or fells it with a stick. If it finds a bush in its retreat, it climbs upon it, and from the top of its asylum beholds the dogs brushing along in fault: this habit is common to it and to the water-rail. It dives, swims, and even swims under water, when hard pushed."

3. The crex, crake, or corn-crek, has been supposed by some to be the same with the water-rail, and that it differs only by a change of colour at a certain season of the year: this error is owing to inattention to their characters and nature, both which differ entirely. The bill of this species is short, strong, and thick, formed exactly like that of the water-hen, and makes a generical distinction. It never frequents watery places; but is always found among corn, grass, broom, or furze. It quits the kingdom before winter; but the water-rail endures our sharpest seasons. They agree in their aversion to flight; and the legs, which are remarkably long for the size of the bird, hang down whilst they are on the wing: they trust their safety to their swiftness on foot, and seldom are sprung a second time but with great difficulty. The land-rail lays from twelve to twenty eggs, of a dull white colour, marked with a few yellow spots: notwithstanding this they are very numerous in this kingdom. Their note is very singular; and, like the quail, it is decoyed into a net by the imitation of its cry, *crek crek crek*, by rubbing hard the blade of a knife on an indented bone. Most of the names given in different languages to this

bird are evidently formed to imitate this singular cry.

They are in greatest plenty in Anglesea, where they appear about the 20th of April, supposed to pass over from Ireland, where they abound. At their first arrival, it is common to shoot seven or eight in a morning. They are found in most of the Hebrides, and the Orkneys. On their arrival they are very lean, weighing only six ounces; but before they leave this island, grow so fat as to weigh above eight. The feathers on the crown of the head and hind part of the neck are black, edged with bay-colour; the coverts of the wings of the same colour, but not spotted; the tail is short, and of a deep bay; the belly white; the legs ash-coloured.

RALLYING, in war, re-assembling or calling together troops broken and put to flight.

RAM, in zoology. See OVIS.

RAM, in astronomy. See ARIES.

RAM, *battering*, in antiquity, a military engine used to batter and beat down the walls of places besieged.

The battering ram was of two sorts; the one rude and plain, the other compound. The former seems to have been no more than a great beam which the soldiers bore on their arms and shoulders, and with one end of it by main force assailed the wall. The compound ram is thus described by Josephus: It is a vast beam, like the mast of a ship, strengthened at one end by a head of iron, something resembling that of a ram, whence it took its name. See Plate Miscel. fig. 196. This was hung by the middle with ropes to another beam which lay across two posts; and hanging thus equally balanced, it was by a great number of men drawn backwards and pushed forwards, striking the wall with its iron head.

Plutarch informs us, that Mark Anthony, in the Parthian war, made use of a ram fourscore feet long; and Vitruvius tells us, that they were sometimes 106, and sometimes 120 feet in length; and to this, perhaps, the force and strength of the engine was in a great measure owing. The ram was managed at one time by a whole century of soldiers, and they being spent, were seconded by another century, so that it played continually without any intermission.

In order to calculate the force of the battering-ram R, suppose it to be 28 inches in diameter, and 180 feet long; and consequently its solid content 750 cubic feet; which, allowing 50 pounds for each foot, will weigh 37500 pounds: and suppose its head of cast-iron, together with three iron-hoops, &c. to be 3612 pounds. Now all these weights added together, make 41112 pounds, equal the weight of the whole ram; which will require 1000 men to move it so as to cause it to strike against the point L of the wall AHIGE, each man moving a weight of 41 pounds. The quantity of motion produced by this action, when the ram moves one foot in a second, may be expressed by the number 41112; which motion or force compared with the quantity of motion in the iron ball B, shot out of the cannon C, will be found equal to it: for a cannon-ball is known to move as fast as sound for about the space of a mile; and if you multiply 36 pounds, the weight of the ball, by 1142, the number of feet which sound moves in one second, you will have the number 41112 for the quantity of motion or force, in the ball B striking at L. And if, after a few strokes given by the battering-ram, the mortar or cement is so loosened, that the piece of the wall ADDFE is at last by a stroke of the ram carried forward from F to K, and so beaten down; the same thing will be performed by a cannon-ball, after an equal number of strokes.

This shews how advantageous the invention of gunpowder is; since we are thereby enabled to give such a prodigious velocity to a small body, that it shall have as great a quantity of motion as a body immensely greater, and requiring more hands to work it: for three men will manage a cannon which shall do as much execution as the above battering-ram, wrought by 1000. The ram whose force is here calculated, is taken at a mean; being larger than some, and less than others, of those used by the antients.

RAM'S-HEAD, in a ship, is a great block belonging to the fore and main halyards. It has three shivers in it, into which the halyards are put, and in a hole at the end of it are reeved the ties.

RAMADAN, a solemn season of fasting among the Mahometans, kept in the ninth month of the Arabic year.

RAMPANT. See HERALDRY.

RAMPART, in fortification, is an elevation of earth round a place capable of resisting the cannon of an enemy; and formed into bastions, curtins, &c. See FORTIFICATION.

RAMPHASTOS, in ornithology, a genus belonging to the order of picæ. The bill is very large, and serrated outwardly. The nostrils are situated behind the base of the beak; and in most of the species the feet are toed, and placed two forwards and two backwards. The tongue is long, narrow, and feathered on the edges. Mr. Latham enumerates fifteen different species, of which the toucans are the most remarkable, and were formerly divided into four or five varieties, though Mr. Latham makes them distinct species, of which we shall only describe that called the red-beaked toucan.

This bird is about the size of a jack-daw, and of a similar shape, with a large head to support its monstrous bill. This bill, from the angles of the mouth to its point, is six inches and a half; and its breadth in the thickest part is a little more than two. Its thickness near the head is one inch and a quarter; and it is a little rounded along the top of the upper chap, the under side being round also; the whole of the bill extremely slight, and but a little thicker than parchment. The upper chap is of a bright yellow, except on each side, which is of a fine scarlet colour; as is also the lower chap, except at the base, which is purple. Between the head and the bill there is a black line of separation all round the base of the bill; in the upper part of which the nostrils are placed, and are almost covered with feathers; which has occasioned some writers to say that the toucan has no nostrils. Round the eyes on each side of the head, is a space of blueish skin, void of feathers; above which the head is black, except a white spot on each side joining to the base of the upper chap. The hinder part of the neck, the back, wings, tail, belly, and thighs, are black. The under side of the head, throat, and the beginning of the breast, are white. Between the white on the breast, and the black on the belly, is a space of red feathers, in the form of a new moon, with its horns upwards. The legs, feet, and claws, are of an ash-colour; and the toes stand like those of parrots, two before and two behind.

It is reported by travellers, that this bird, though furnished with so formidable a beak, is harmless and gentle, being so easily made tame as to sit and hatch its young in houses. It feeds chiefly upon pepper, which it devours very greedily. It builds its nest in holes of trees, which have been previously scooped out for this purpose. There is no bird secures its young better from external injury than the toucan. It has not only birds, men, and serpents, to guard against, but a numerous tribe of monkeys, still more prying, mischievous, and hungry, than all the rest. The toucan, however, scoops out its nest into the hollow of some tree, leaving only a hole large enough to go in and out at. There it sits, with its great beak, guarding the entrance; and, if the monkey ventures to offer a visit of curiosity, the toucan gives him such a welcome, that he presently thinks proper to retire, and is glad to escape with safety.

This bird is only found in the warm climates of South America, where it is in great request, both for the delicacy of its flesh, which is tender and nourishing, and for the beauty of its plumage, particularly the feathers of the breast. The skin of this part the Indians pluck off, and when dry glue to their cheeks; and this they consider as an irresistible addition to their beauty. See Plate Nat. Hist. fig. 342.

RANA, *frog*, a genus of amphibia of the order reptiles; the generic character is, body four-footed, without tail, and naked, or without any integument but the skin.

This genus may be divided into three sections, viz. 1. Frogs, commonly so called, or ranæ, with light active bodies, and which leap when disturbed. 2. Slender-limbed frogs, hylæ, calamitæ, or ranæ arboreæ, viz. such as have light bodies, very slender limbs, and toes terminating in flat, circularly expanded, tips, enabling the animals to adhere at pleasure to the surface even of the smoothest bodies. Several of this division generally reside on trees, adhering by their toes to the lower surfaces of the leaves and branches. 3. Toads, bufones, or such as have large heavy bodies, short thick limbs, and which rather crawl than leap when disturbed.

1. Rana temporaria, the common frog, is the most common of all the European species, being almost every where seen in moist situations, or wherever it can command a sufficient quantity of insects, worms, &c. on which it feeds. In colour it varies considerably, but its general tinge is olive-brown, variegated on the upper parts of the body and limbs with irregular blackish spots; those on the limbs being mostly disposed in a transverse direction: beneath each eye is a longish mark or patch, reaching to the setting on of the fore-legs, and which seems to form one of its principal specific distinctions.

It is generally in the month of March that the frog deposits its ova or spawn, consisting of a large heap or clustered mass of gelatinous transparent eggs, in each of which is imbedded the embryo, or tadpole, in the form of a round black globule. The spawn commonly lies more than a month, or sometimes five weeks, before the larvæ or tadpoles are hatched from it; and during this period each egg gradually enlarges in size, and a few days before the time of exclusion the young animals may be perceived to move about in the surrounding gluten. When first hatched, they feed on the remains of the gluten in which they were imbedded; and in the space of a few days, if narrowly examined, they will be found to be furnished, on each side the head, with a pair of ramified branchiæ or temporary organs, which again disappear after a certain space. These tadpoles are so perfectly unlike the animals in their complete state, that a person not conversant in natural history would hardly suppose them to bear any relationship to the frog; since, on a general view, they appear to consist merely of head and tail. Their motions are extremely lively, and they are often seen in such vast numbers as to blacken the whole water with their legions. They live on the leaves of duckweed and other small water-plants, as well as on various kinds of animalcules, &c. and when arrived at a larger size, they may even be heard to gnaw the edges of the leaves on which they feed, their mouths being furnished with extremely minute teeth or denticulations. The tadpole is also furnished with a small kind of tubular sphincter or sucker beneath the lower jaw, by the help of which it hangs at pleasure to the under surface of aquatic plants, &c. From this part it also occasionally hangs, when very young, by a thread of gluten, which it seems to manage in the same manner as some of the smaller slugs have been observed to practise. Its interior organs differ, if closely inspected, from those of the future frog, in many respects; the intestines in particular are always coiled into a flat spiral, in the manner of a cable in miniature.

When the tadpoles have arrived at the age of about five or six weeks, the hind legs make their appearance, gradually increasing in length and size; and, in about a fortnight afterwards, or sometimes later, are succeeded by the fore legs, which are indeed formed beneath the skin much sooner, and are occasionally protruded and again retracted by the animal through a small foramen on each side of the breast, and are not completely stretched forth till the time just mentioned. The animal now bears a kind of ambiguous appearance, partaking of the form of a frog and a lizard. The tail at this period begins to decrease, at first very gradually, and at length so rapidly as to become quite obliterated in the space of a day or two afterwards. The animal now ventures upon land, and is seen wandering about the brinks of its parent waters, and sometimes in such multitudes as to cover a space of many yards in extent. This is the phenomenon which has so frequently embarrassed the minds not only of the vulgar, but even of some superior characters in the philosophic world; who, unable to account for the legions of these animals with which the ground is occasionally covered in certain spots, at the close of summer, have been led into the popular belief of their having descended from the clouds in showers.

As soon as the frog has thus assumed its perfect form, it feeds no longer on vegetables but on animal food; supporting itself on small snails, worms, &c. and insects. For the readier obtaining its prey, the structure of its tongue is extremely well calculated, being so situated that the root is attached to the fore rather than the hind part of the mouth; and when at rest, lies backwards, as if the animal was swallowing the tip. By this means the creature is enabled to throw it out to some distance from the mouth, which is done with great celerity, and the bifid and glutinous extremity secures the prey, which is swallowed with an instantaneous motion, so quick that the eye can scarcely follow it.

The frog can hardly be said to arrive at its full size till the age of about five years, and is supposed to live at least twelve or fifteen years.

The frog is extremely tenacious of life, and, like other amphibia, will survive for a considerable space the loss of many of its organs. If confined entirely under water, it is still enabled to support its existence for several days, as appears by sir Thomas Brown's experiment, who kept a frog under water six days. On the contrary, it cannot so well dispense with the want of water, and is unable to survive too long an exposure to a dry air and a hot sun. It is, therefore, particularly careful to secure a retreat where it may enjoy the benefit of shade and a sufficient supply of moisture. It delights, however, to bask occasionally in a moderate sunshine, and is unable to support severe cold.

2. Rana esculenta, green frog. This species is the largest of the European frogs, and is found plentifully in France, Italy, Germany, and many other parts of Europe, but is a rare animal in England. In its general appearance it extremely resembles the common frog, but is of larger size, and of an olive-green colour, distinctly and strongly marked on the upper parts of the body with moderately large and somewhat rounded black spots or patches; the limbs are elegantly marked or barred transversely with bands of the same colour. The head is rather larger and sharper in proportion than that of the common frog; and the long deep-brown patch under each eye, which forms so constant and conspicuous a character in that animal, is much less distinct, and sometimes even entirely wanting. The proportion of the limbs is nearly the same as in the common frog, and the hind feet are very strongly palmated.

The green frog is a very voracious animal, and will occasionally seize on young birds of various kinds, mice, and even young ducklings which happen to stray too far from their parents, swallowing them whole like the rest of its prey. It arrives at its full growth in about four years, begins to breed at the age of five years, and lives to about sixteen.

3. Rana catesbeiana, bull-frog. This remarkable species is not uncommon in many parts of North America, where it is known by the name of the bull-frog, its voice resembling the distant lowing of that animal. It grows to a very large size, and is about 18 inches from the nose to the end of the hind feet. Its colour, on the upper parts, is a dusky olive or brownish, somewhat irregularly marked with numerous deep-brown spots; while the under parts are of a pale or whitish cast, with a tincture of yellowish green.

4. Rana ignea, fire-frog, is a native of Germany, Italy, and many other parts of Europe, but is not found in England. Its colour on the upper parts is a dull olive-brown, the skin being marked with large and small tubercles; round the edges of the mouth is placed a row of blackish streaks or perpendicular spots. The under parts both of the body and limbs are orange-coloured, spotted or variegated with irregular markings of dull blue. It is from the colour of the under surface that this species has obtained its titles of bufo igneus, fire-frog, &c.

This animal may be considered rather as an aquatic than terrestrial species, being rarely found on land, but chiefly inhabiting turbid stagnant waters, in which, in the month of June, it deposits its spawn, the ova being much larger in proportion than in most others of the genus. The tadpoles are hatched towards the end of June, and are of a pale yellowish-brown colour; and when young are often observed to hang from the surface of leaves, &c. by a glutinous thread proceeding from the small tube or sucker beneath the lower lip.

The fire-frog is a lively, active animal; leaping and swimming with equal or even superior agility to the common frog. When surprised on land, or unable to escape, it squats close to the ground, at the same time turning back its head and limbs in a singular manner; and if farther teased or irritated, evacuates from the hinder part of the thighs a kind of saponaceous frothy fluid, of no bad scent, but which in some circumstances has been found to excite a slight sensation of acrimony in the eyes and nostrils. This species is observed to breed at the age of three years, and may be supposed to live about ten; but this is not entirely ascertained. Its voice, according to Roesel, is sharper or lighter than in other frogs, less disagreeable, and in some degree resembling a kind of laugh: according to authors, however, it rather resembles the tone of a bell, or the note of a cuckoo; for which reason the animal has been called rana bombina. The male only is vocal.

5. Rana piscis, larva, or tadpole. This animal is a native of South America, and seems to be more particularly found in Surinam than in other parts. In its general form it very much resembles the rana temporaria, or common European frog; and is, when living, of a yellowish olive-colour, spotted and variegated on the body and limbs with rufous or yellowish brown; the principal mark of distinction from others of the genus being the somewhat oblique longitudinal stripes on the hind legs: the fore feet have only four toes, and are unwebbed; but the hind feet have five, and are very deeply palmated to the very ends or tips of the toes; and near the thumb or shortest toe is an oblong callus, resembling an additional or spurious toe.

The tadpole of this frog, from its very large size, the strong and muscular appearance of the tail, and the ambiguous aspect which it exhibits in the latter part of its progress toward its complete or ultimate form, has long continued to constitute the paradox of European naturalists; who, however strong and well-grounded their suspicions might be relative to its real nature, and the mistake of most describers, were yet obliged, in some measure, to acquiesce in the general testimony of those who had seen it in its native waters, and who declared it to be at length transmuted, not into a frog, but a fish! and it was even added by some, that it afterwards reverted to its tadpole form again!! That it is really no other than a frog in its larva or tadpole state, will be evident to every one who considers its structure; and more especially, if it is collated with the tadpole even of some European frogs. Like our European tadpoles, this animal, according to the more or less advanced state in which it is found, is furnished either with all the four legs, or with only the two hinder ones: it also sometimes happens that in the largest-sized of these tadpoles, exceeding perhaps the length of six or eight inches, the hind legs alone appear; while in those of far smaller size both the fore and hind legs are equally conspicuous.

It will readily appear that the larva of this frog is larger in proportion to the complete animal than in any other species hitherto discovered. It may also be not improper to observe, that perhaps all the specimens of these very large tadpoles occurring in museums, may not be those of the rana paradoxa in particular, but of some other American, African, or Asiatic frogs, as the R. ocellata, marina, &c. See Frog-fish, Vol. I. p. 780.

Hylæ, or frogs with rather slender bodies, long limbs, and the tips of the toes flat, orbicular, and dilated.

6. Rana zebra, zebra-frog, appears to be by far the largest of all the hylæ, or slender-bodied frogs, and is, according to Seba, a native of Carolina and Virginia. Its colour is an elegant pale rufous-brown, beautifully marked on the back and limbs, and even to the ends of the toes, with transverse chesnut-coloured bands, which on the limbs are double and much more numerous than on the back; the fore feet are tetradactylous, and the hind pentadactylous; the head is large in proportion, the eyes protuberant, and the mouth wide. It measures about five inches.

7. Rana arborea, tree-frog. In the beauty of its colours, as well as in the elegance of its form and the agility of its movements, the tree-frog exceeds every other European species. It is a native of France, Germany, Italy, and many other European regions, but is not found in the British islands. Its principal residence, during the summer months, is on the upper parts of trees, where it wanders among the foliage in quest of insects, which it catches with extreme celerity, stealing softly toward its prey in the manner of a cat towards a mouse, and when at the proper distance, seizing it with a sudden spring, frequently of more than a foot in height. It often suspends itself to the under parts of the leaves, thus continuing concealed beneath their shade. Its size is smaller than any other European frog, except the fire-frog. Its colour on the upper parts is green, more or less bright in different individuals; the abdomen is whitish, and marked by numerous granules; the under surface of the limbs is reddish, and the body marked on each side by a longitudinal blackish or violet-coloured streak. The body is smooth above, and moderately short above; the hind legs are very long and slender; the fore feet have four and the hind feet five toes, all of which terminate in rounded, flat, and dilated tips, the under surface of which, being soft and glutinous, enables the animal to hang with perfect security from the leaves of trees, &c. The skin of the abdomen is also admirably calculated by nature for this peculiar power of adhesion, being covered with small glandular granules in such a manner as to fasten closely even to the most polished surface; and the animal can adhere at pleasure to that of glass, in whatever position or inclination it is placed, by merely pressing itself against it.

Though the tree-frog inhabits the woods during the summer months, yet on the approach of winter it retires to the waters, and there submerging itself in the soft mud, or concealing itself beneath the banks, remains in a state of torpidity, and again emerges in the spring, at which period it deposits its spawn in the waters, like the rest of this genus. During their residence among the trees, they are observed to be particularly noisy on the approach of rain; so that they may be considered, in some measure, as a kind of living barometers; more especially the males, which, if kept in glasses, and supplied with proper food, will afford an infallible presage of the changes of weather.

Toads. 8. Rana bufo, common toad. Of all the European toads, this seems to be the most universally known; at least, in its complete or perfect form. It is found in gardens, woods, and fields; and frequently makes its way into cellars, or any obscure recesses in which it may occasionally conceal itself, and where it may find a supply of food, or a security from too great a degree of cold. In the early part of spring, like others of this genus, it retires to the waters, where it continues during the breeding-season, and deposits its ova or spawn in the form of double necklace-like chains or strings of beautifully transparent gluten, and of the length of three or four feet.

The toad is an animal too well known to require any very particular description of its form. It may be necessary to observe that it is always covered by tubercles, or elevations on the skin, of larger or smaller size in different individuals; and that the general colour of the animal is an obscure brown above, much paler and irregularly spotted beneath.

The toad arrives at a considerable age; its general term of life being supposed to extend to 15 or even 20 years: and Mr. Pennant, in his British Zoology, gives us a curious account, communicated by a Mr. Arscott of Tehott in Devonshire, of a toad's having lived, in a kind of domestic state, for the space of more than 40 years, and of having been in a great degree tamed, or reclaimed from its natural shyness or desire of concealment; since it would always regularly come out of its hole at the approach of its master, &c. in order to be fed. It grew to a very large size, and was considered as so singular a curiosity, that even ladies, laying aside their usual aversion and prejudices, requested to see the favourite toad. It was, therefore, often brought to table, and fed with various insects, which it seized with great celerity, and without seeming to be embarrassed by the presence of company. This extraordinary animal generally resided in a hole beneath the steps of the house-door, fronting the garden; and might probably have survived many years longer, had it not been severely wounded by a raven, which seized it before it could take refuge in its hole; and notwithstanding it was liberated from its captor, it never again enjoyed its usual health, though it continued to live above a year after the accident happened.

With respect to the supposed venomous qualities of the toad, from the experiments of Laurenti, it appears that small lizards, on biting the common toad, were for some time disordered and paralytic, and even appeared to be dead, but in a few hours were completely recovered.

It is also observed, that dogs, on seizing a toad, and carrying it for some little time in their mouth, will appear to be affected with a very slight swelling of the lips, accompanied by an increased evacuation of saliva; the mere effect of the slightly acrimonious fluid which the toad on irritation exudes from its skin, and which seems, in this country at least, to produce no dangerous symptoms in such animals as happen to taste or swallow it. The limpid fluid also, which this animal discharges when disturbed, is a mere watry liquor, perfectly free from any acrimonious or noxious qualities, and appearing to be no other than the contents of a peculiar reservoir, common to this tribe, destined for some purpose in the economy of the animals which does not yet appear to be clearly understood. The common toad may therefore be pronounced innoxious, or perfectly free from any poisonous properties, at least with respect to any of the larger animals; and the innumerable tales recited by the older writers of its supposed venom, appear to be either gross exaggerations, or else to have related to the effects of some other species mistaken for the common toad; it being certain that some of this genus exude from their skin a highly acrimonious fluid.

It might seem unpardonable to conclude the history of this animal without mentioning the very extraordinary circumstance of its having been occasionally discovered enclosed or imbedded, without any visible outlet, or even any passage for air, in the substance of wood, and even in that of stone or blocks of marble.

On this subject a curious experiment was made by Mons. Herrissant of the French academy, in consequence of an assertion, that in the year 1771, on pulling down a wall at a seat belonging to the duke of Orleans, and which had been built 40 years, a living toad had been found in it; its hind feet being confined or imbedded in the mortar. M. Herrissant therefore, in the presence of the academy, inclosed three toads in as many boxes, which were immediately covered with a thick coat of plaister or mortar, and kept in the apartments of the academy. On opening these boxes eighteen months afterwards, two of the toads were found still living: these were immediately re-inclosed; but on being again opened some months after, were found dead. These experiments are perhaps not very conclusive; and only appear to prove what was before well known, viz. that the toad, like many other amphibia, can support a long abstinence, and requires but a small quantity of air: but in the accounts generally given of toads discovered in stones, wood, &c. the animals are said to have been completely impacted or imbedded, and without any space for air.

9. Rana viridis. The green toad is a native of Germany and some other parts of Europe, and seems to have been first described by Valisneri, and afterwards by Laurenti, who informs us that it inhabits the cavities of walls about Vienna, and is distinguished by its greenish and confluent spots on the upper parts, disposed on a pale or whitish ground, and scattered over with tubercles. Each of the green spots or patches is also bounded by a blackish margin, and the whole pattern has a somewhat rudely geographical or map-like appearance. The odour of this species is very strong; resembling that of the common black or garden nightshade, but much more powerful, so as to fill a whole room. The female is of a browner cast than the male. In winter this species retires under ground, and, like others of the genus, frequents the waters at the breeding season.

10. Rana dubia, or musica. Of this animal a specimen is preserved in the British Museum, under the title of rana musica: its size is that of a common toad, but the shape of the body differs, seeming gradually to decrease from the shoulders to the hind legs, somewhat in the manner of the hylæ or tree-frogs. Its colour, so far as can be determined from the specimen long preserved in spirit of wine, appears to have been a moderately deep-brown above, and pale or whitish beneath, slightly marbled or variegated with brown. The whole upper surface is beset with distinct oval pustules or tubercles.

Whether this is the species intended by Linnæus, under the name of rana musica, may perhaps be questioned. In the Systema Naturæ he refers to no author or figure, but informs us that the animal is a native of Surinam, and that it has a musical voice. See Plate Nat. Hist. fig. 344.

11. Rana cornuta, horned toad. Among the whole tribe of amphibia, it is, perhaps, difficult to find an animal of a more singular appearance than this, which may be regarded as of a more deformed and hideous aspect than even the pipa, or toad of Surinam. This arises not so much from the general shape of the animal, as from the extraordinary structure of the upper eyelids, which are so formed as to resemble a pair of short sharp-pointed horns; while the width of the mouth is such as to exceed that of any other species, and even to equal half the length of the body itself. The skin of the body, both above and below, is of a cinereous yellow, striped with lines of obscure greyish brown. Along the back runs a broad white band, commencing at the head, and thence decreasing gradually, so as to appear narrow over the hind parts: it is also beset with small specks like pearls. All the rest of the body is rough, with sharp spines, except the head, which is variegated with white, and the abdomen, which is of a deep rufous yellow. The legs are surrounded by a kind of bands or fillets; and the toes are marked in a similar manner, and resemble in some degree the human fingers, and are four in number on the fore legs, and five on the hind: the hind feet are also webbed. The head is very large and thick, and when the mouth is opened, exhibits a broad and thick tongue, shaped somewhat like an oyster, and fastened in front to the lower jaw, but loose behind as in frogs; it is also covered over with papillæ. The female agrees in all respects with the male, except that the mouth is still wider, and the front is variegated in a somewhat different manner. See Plate Nat. Hist. fig. 343.

Seba seems to have been misinformed as to the native country of this species, which he imagined to be Virginia; but the animal is now known to be a native of South America only.

12. Rana pipa. This also is one of those animals which, at first view, every one pronounces deformed and hideous; the general uncouthness of its shape being often aggravated by a phenomenon unexampled in the rest of the animal world, viz. the young in various stages of exclusion, proceeding from cells dispersed over the back of the parent.

The size of the pipa considerably exceeds that of the common toad: the body is of a flattish form; the head subtriangular; the mouth very wide, with the edges or corners furnished with a kind of short cutaneous and lacerated appendage on each side: in the male, however, the head is rather oval than triangular, and the parts just mentioned less distinct; the fore feet are tetradactylous, the toes long and thin, and each divided at the tip into four distinct portions or processes, each of which, if narrowly inspected with a magnifier, will be found to be again obscurely subdivided almost in a similar manner; the hind feet are five-toed, and very widely webbed; the web reaching to the very tips of the toes. The male pipa is larger than the female, measuring sometimes not less than seven inches from the nose to the end of the body; the nose in both sexes is of a somewhat truncated form, like that of a mole or hog, and the eyes extremely small; from each eye, in the female, run two rows of granules, or glandular points, to the middle of the back; the whole body is also covered with similar points or glandules, but smaller than the former: in the male a single row of granules proceeds from each eye down the back, instead of a double row as in the female: these points or granules are also larger than in the female, and gradually decrease in size as they approach the lower part of the back: the skin round the neck, in both sexes, forms a kind of loose or wrinkled collar: the abdomen of the male is of a browner tinge than that of the female, and is sometimes obscurely spotted with yellow; but the general colour, both of the male and female pipa, is a dark or blackish brown.

It was for a long time supposed that the ova of this extraordinary animal were produced in the dorsal cells, without having been first excluded in the form of spawn; but later observations have proved that a still more extraordinary process takes place; and that the spawn after exclusion is received into the open cells of the back, and there concealed till the young have arrived at maturity. The female pipa deposits her eggs or spawn at the brink of some stagnant water; and the male collects or amasses the heap of ova, and deposits them with great care on the back of the female, where, after impregnation, they are pressed into the cellules, which are at that period open for their reception, and afterwards close over them; thus retaining them till the period of their second birth; which happens in somewhat less than three months, when they emerge from the back of the parent in their complete state. During the time of their concealment, however, they undergo the usual change of the rest of this genus, being first hatched from the egg in the form of a tadpole; and gradually acquire their complete shape some time before their exclusion.

According to Fermin, the pipa is calculated by nature for producing but one brood of young; and, compared with the rest of the genus, it can by no means be considered as a very prolific animal; the number of young produced by the female which he observed, amounted to 75, and were all excluded within the space of five days.

RANCIDITY. See Oils.

RANDOM SHOT, in gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly or point-blank. The utmost random of any piece is about ten times as far as the bullet will go point-blank. The bullet will go farthest when the piece is mounted to about 45° above the level range. See Gunnery, and Projectiles.

RANGE, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. If the piece is in a line parallel to the horizon, it is called the right or level range: if it is mounted to 45°, it is said to have the utmost range; all others between 00 and 45° are called the intermediate ranges.

RANGER, a sworn officer of a forest, appointed by the king's letters-patent, whose business is to walk through his charge, to drive back the deer out of the purlieus, &c. and to present all trespasses within his jurisdiction at the next forest-court.

RANGES, in a ship, two pieces of timber that go across from side to side; the one on the forecastle, a little abaft the fore-mast; and the other in the beak-head, before the wouldings of the bowsprit.

RANK, in war, is a row of soldiers placed side by side.

To double the ranks is to put two ranks into one. To close the ranks is to bring the men nearer: and to open them, is to set them farther apart.

Rank, the order or place assigned a person suitable to his quality or merit. See Precedence.

Rank *and precedence*, in the army and navy, are as follow:

Engineers' rank. Chief, as colonel; director, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner engineer, as ensign.

Navy rank. Admiral, or commander-in-chief of his majesty's fleet, has the rank of a field-marshal; admirals with their flags on the main-top-mast head, rank with generals of horse and foot; vice-admirals, with lieutenant-generals; rear-admirals, as major-generals; commodores with broad pendants, as brigadier-generals; captains of post-ships, after three years from the date of their first commission, as colonels; other captains commanding post ships, as lieutenant-colonels; captains not taking post, as majors; lieutenants, as captains.

Rank between the Army, Navy, and Governors.

Army.	Navy.	Governors.
General in chief	Admiral in chief	Commander in chief of the forces in America
Generals of horse	Admiral with a flag at the main-top-mast	Captain-generals of provinces
Lieutenant-generals	Vice-admirals	Lieutenant-generals of provinces
Major-generals	Rear-admirals	Lieutenant-governors and presidents
Colonels	Post-captains of 3 years	Lieutenant-governors not commanding
Lieutenant-colonels	Post-captains	Governors of charter colonies
Majors	Captains	Deputy-governors
Captains	Lieutenants	Established by the king, 1760.

RANUNCULUS, *crowfoot*, a genus of the polygamia order, in the polyandria class of plants; and in the natural method ranking under the 26th order, multisiliquæ. The calyx is pentaphyllous; there are five petals, each with a melliferous pore on the inside of the heel; the seeds naked.

There are 59 different species of this genus; six or eight of which claim general esteem as flowery plants for ornamenting the gardens. The rest, as the common crowfoot, &c. are common weeds in the fields, waters, and pasture-ground, not having merit for garden-culture. Of the garden kinds, the principal sort is the Asiaticus or Turkey and Persian ranunculus, which comprises many hundred varieties of large, double, most beautiful flowers, of various colours: but several other species having varieties with fine double flowers, make a good appearance in a collection; though as those of each species consist only of one colour, some white, others yellow, they are inferior to the Asiatic ranunculus, which is large, and diversified a thousand ways in rich colours, in different varieties. All the garden kinds, however, in general effect a very agreeable diversity in assemblage in the flower compartments, &c. and they being all very hardy, succeed in any open beds and borders, &c.

The Asiatic species in all its varieties will succeed in any light, rich, garden earth; but the florists often prepare a particular compost for the fine varieties, consisting of good garden-mould or pasture-earth, sward and all, a fourth part of rotted cow-dung, and the like portion of sea-sand; and with this they prepare beds four feet wide, and two deep: however, in default of such compost, use beds of any good light earth of your garden; or, if necessary, it may be made light and rich with a portion of drift-sand and rotten dung, cow-dung is most commonly recommended; but they will also thrive in beds of well-wrought kitchen-garden earth, and they often prosper well in the common flower-borders.

The season for planting the roots is spring; and it may be performed any time in February, or as soon as the weather is settled.

All the varieties of the Asiatic ranunculus propagate abundantly by offsets from the root; and new varieties are gained by seed. The juice of many species of ranunculus is so acrid as to raise blisters on the skin, and yet the roots may be eaten with safety when boiled.

RAPE. See Brassica.

Rape, in law, is where a man has carnal knowledge of a woman by force, and against her will; by 18 Eliz. c. 7, if any person shall unlawfully and carnally know and abuse any woman-child under the age of ten years, whether with her consent or against it, he shall be punished as for a rape. And it is not a sufficient excuse in the ravisher, to prove that she is a common strumpet; for she is still under the protection of the law, and may not be forced. Nor is the offence of a rape mitigated by shewing that the woman at last yielded to the violence, if such her consent was forced by fear of death or duress; nor is it any excuse that she consented after the fact. 1 Haw. 108.

The civilians make another kind of rape, called rape of subordination or seduction; which is seducing a maid either to uncleanness or marriage, and that by gentle means, provided there is a considerable disparity in the age and circumstances of the parties.

Rape is also a name given to a division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds; thus Sussex is divided into six rapes, every one of which, besides its hundreds, has a castle, a river, and a forest, belonging to it. The like parts in other counties are called tithings, lathes, or wapentakes.

RAPHANUS, *radish*, a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. The calyx is close: the siliqua torose, or swelling out in knots, subarticulated, and round. There are two melliferous glandules between the shorter stamina and the pistil, and two between the longer stamina and the calyx. There are six species; the sativus, or common garden-radish, is best known, and of this there are several varieties. They are annual plants, which being sown in the spring, attain perfection in two or three months, and shoot up soon after into stalk for flower and seed, which, ripening in autumn, the whole plant, root and top, perishes; so that a fresh supply must be raised annually from seed in the spring, performing the sowings at several different times, from about Christmas until May, in order to continue a regular succession of young tender radishes throughout the season, allowing only a fortnight or three weeks interval between the sowings; for one crop will not continue good longer than that space of time, before they will either run to seed, or become tough, sticky, and too hot to eat.

RAPHIDIA, a genus of insects of the order neuroptera. The generic character is, mouth with two teeth; head depressed, horny; feelers four; stemmata three; wings deflex; antennæ the length of thorax, which is cylindric, and elongated in front; tail of the female furnished with a recurved lax bristle. This genus contains but few species, the most remarkable of which is the raphidia ophiopsis of Linnæus; a smallish fly, with rather large transparent wings, and a narrow thorax, stretching forwards in a remarkable manner. It is found on trees, &c. in summer, but is rather a rare insect: the pupa, according to Linnæus, resembles the complete insect, but is destitute of wings.

Raphidia cornuta is a large species, equal in size to one of the larger dragon-flies, and is distinguished by its very long hornlike jaws, which extend far beyond the thorax, and are terminated by a bifid tip: the wings are large, reticulated, and semitransparent. It is a native of North America.

Raphidia mantispa is a small species, but little superior is size to the R. ophiopsis, and is a native of some of the warmer parts of Europe. It has the habit of the genus mantis, and it is even doubtful whether it should not more properly be referred to that genus.

RAREFACTION, in physics, the act whereby a body is brought to possess more room, or appear under a larger bulk, without the accession of any new matter. This is commonly the effect of caloric, as has long been universally allowed. In many cases, however, philosophers have attributed it to the action of a repulsive principle. However, from the many discoveries concerning the nature and properties of the electric fluid and caloric, there is the greatest reason to believe that this repulsive principle is no other than caloric or fire.

RASANT, or Razant, in fortification. Rasant flank, or line, is that part of the curtin or flank whence the shot exploded rase, or glance along, the surface of the opposite bastion.

RASH, in medicine, an eruption upon the skin, thrown out in fevers or surfeits. See Medicine.

RAT. See Mus.

RATAFIA, a spirituous liquor, prepared from the kernels, &c. of several kinds of fruit, particularly of cherries and apricots. Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmegs, cloves; and to twenty pounds of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it is tapped. Ratafia of apricots is prepared two ways, viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days, then straining the liquor, and putting it up for use: or else by infusing the apricots cut in pieces in brandy, for a day or two, passing it through a straining bag, and then putting in the usual ingredients.

RATCH, or Rash, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, and make the clock strike. See Clock-work.

RATCHETS, in a watch, are the small teeth at the bottom of the fusee, or barrel, which stops it in winding up.

RATES, in the navy, the orders or classes into which the ships of war are divided, according to their force and magnitude. The regulation which limits the rates of men of war to the smallest number possible, seems to have been dictated by considerations of political economy, or of the simplicity of the service in the royal dock-yards. The British fleet is accordingly distributed into six rates, exclusive of the inferior vessels that usually attend on naval armaments; as sloops of war, armed ships, bomb-ketches, fire-ships and cutters, or schooners commanded by lieutenants. Ships of the first rate mount 100 cannon, having 42-pounders on the lower deck, 24-pounders on the middle deck, 12-pounders on the upper deck, and 9-pounders on the quarter-deck and forecastle. They are manned with 850 men, including their officers, seamen, marines, and servants.

In general, the ships of every rate, besides the captains, have the master, the boatswain, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the captain, have their mates or assistants, in which are comprehended the sail-maker, the master at arms, the armourer, the captain's clerk, the gunsmith, &c. The number of other officers is always in proportion to the rate of the ship. Thus a first-rate has six lieutenants, six master's mates, twenty-four midshipmen, and five surgeon's mates, who are considered as gentlemen: besides the following petty officers; quarter-masters and their mates, fourteen; boatswain's mates and yeomen, eight; gunner's mates and assistants, six; quarter-gunners, twenty-five; carpenter's mates, two, besides fourteen assistants; with one steward, and steward's mate to the purser.

If the dimensions of all ships of the same rate were equal, it would be the simplest and most perspicuous method to collect them into one point of view in a table: but as there is no invariable rule for the general dimensions, we must content ourselves with but a few remarks on ships of each rate, so as to give a general idea of the difference between them.

The Victory, one of the last-built of our first-rates, and ever memorable for being commanded by lord Nelson in the glorious battle of Trafalgar, is 222 feet 6 inches in length, from the head to the stern; the length of her keel, 151 feet 3 inches; that of her gun-deck, or lower deck, 186 feet; her extreme breadth is 51 feet 10 inches; her depth in the hold, 21 feet 6 inches; her burthen 2162 tons; and her poop reaches 6 feet before the mizen-mast.

Ships of the second rate carry 90 guns upon three decks, of which those on the lower battery are 32-pounders; those on the middle, 18-pounders; on the upper deck, 12-pounders; and those on the quarter-deck, 6-pounders, which usually amount to four or six. Their complement of men is 750, in which there are 6 lieutenants, four master's-mates, 24 midshipmen, and four surgeon's-mates, 14 quarter-masters and their mates, eight boatswain's mates and yeomen, six gunner's mates and yeomen, with 22 quarter-gunners, two carpenter's-mates with 10 assistants, and one steward and steward's mate.

Ships of the third rate carry from 64 to 80 cannon, which are 31, 18, and 9-pounders. The 80-gun ships, however, begin to grow out of repute, and to give way to those of 74, 70, &c. which have only two whole batteries; whereas the former have three, with 28 guns planted on each, the cannon of their upper deck being the same as those on the quarter-deck and forecastle of the latter, which are 9-pounders. The complement in a 74 is 650, and in a 64, 500 men; having, in peace, four lieutenants, but in war, five; and when an admiral is aboard, six. They have three master's-mates, 16 midshipmen, three surgeon's-mates, 10 quarter-masters and their mates, six boatswain's-mates and yeomen, four gunner's-mates and yeomen, with 18 quarter-gunners, one carpenter's-mate with eight assistants, and one steward and steward's-mate under the purser.

Ships of the fourth rate mount from 60 to 50 guns, upon two decks, and the quarter-deck. The lower tier is composed of 24-pounders, the upper tier of 12-pounders, and the cannon on the quarter-deck and forecastle are 6-pounders. The complement of a 50-gun ship is 350 men, in which there are three lieutenants, two master's-mates, 10 midshipmen, two surgeon's-mates, eight quarter-masters and their mates, four boatswain's mates and yeomen, one gunner's-mate and one yeoman, with 12 quarter-gunner's, one carpenter's-mate and six assistants, and a steward and steward's-mate.

Vessels of war under the fourth rate, and above the rate of sloops, are usually comprehended under the general name of frigates, and never appear in the line of battle. They are divided into the fifth and sixth rates; the former mounting from 50 to 32 guns, and the latter from 28 to 20. The largest of the fifth rate have two decks of cannon, the lower battery being of 18-pounders, and that of the upper-deck of 9-pounders; but those of 36 and 32 guns have one complete deck of guns, mounting 12-pounders, besides the quarter-deck and forecastle, which carry 6-pounders. The complement of a ship of 44 guns is 280 men; and that of a frigate of 36 guns, 240 men. The first has three, and the second two lieutenants; and both have two master's-mates, six midshipmen, two surgeon's-mates, six quarter-masters and their mates, two boatswain's-mates and one yeoman, one gunner's mate and one yeoman, with 10 or 11 quarter-gunners, and one purser's steward.

Frigates of the 6th rate carry 9-pounders, those of 28 guns having 3-pounders on their quarter-deck, with 200 men for their complement; and those of 24, 160 men: the former have two lieutenants, the latter one; and both have two master's-mates, four midshipmen, one surgeon's-mate, four quarter-masters and their mates, one boatswain's-mate and one yeoman, one gunner's-mate and one yeoman, with six or seven quarter-gunners, and one purser's-steward.

The sloops of war carry from 18 to 8 cannon: the largest have six-pounders; and the smallest, viz. those of 8 or 10 guns, four-pounders. Their officers are generally the same as in the 6th rates, with little variation; and their complements of men are from 120 to 60, in proportion to their force or magnitude. Bomb-vessels are on the same establishment as sloops; but fire-ships and hospital-ships are on that of fifth rates.

Nothing more evidently manifests the great improvement of the marine art, and the degree of perfection to which it has arrived in Britain, than the facility of managing our first rates; which were formerly esteemed incapable of government, unless in the most favourable weather of the summer. Ships of the second rate, and those of the third, which have three decks, carry their sails remarkably well, and labour very little at sea. They are excellent in a general action, or in cannonading a fortress. Those of the third rate, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action, and in general to suit the different exigencies of the naval service. The fourth-rates may be employed on the same occasions as the third-rates, and may be also destined amongst the foreign colonies, or on expeditions of great distance; since these vessels are usually excellent for keeping and sustaining the sea. Vessels of the fifth rate are too weak to suffer the shock of a line of battle; but they may be destined to lead the convoys of merchant-ships, to protect the commerce in the colonies, to cruize in different stations, to accompany squadrons, or be sent express with necessary intelligence and orders. The same may be observed of the sixth-rates. The frigates, which mount from 28 to 38 guns upon one deck, with the quarter-deck, are extremely proper for cruizing against privateers, or for short expeditions, being light, long, and usually excellent sailers.

RATEEN, in commerce, a thick woollen stuff, quilled, woven on a loom with four treadles, like serges, and other stuffs, that have the whale or quilling. There are some rateens dressed and prepared like cloths; others left simply in the hair, and others where the hair or knap is frized.

RATIO, in arithmetic and geometry, is that relation of homogeneous things which determines the quantity of one from the quantity of another, without the intervention of a third.

Two numbers, lines, or quantities, A and

B, being proposed, their relation one to another may be considered under one of these two heads: 1. How much A exceeds B, or B exceeds A; and this is found by taking A from B or B from A, and is called arithmetical reason, or ratio. 2. Or how many times, and parts of a time, A contains B, or B contains A; and this is called geometric reason or ratio; (or, as Euclid defines it, it is the mutual habitude, or respect, of two magnitudes of the same kind, according to quantity; that is, as to how often the one contains, or is contained in, the other;) and is found by dividing A by B, or B by A; and here note, that that quantity which is referred to another quantity, is called the antecedent of the ratio; and that to which the other is referred, is called the consequent of the ratio; as, in the ratio of A to B, A is the antecedent, and B the consequent. Therefore any quantity, as antecedent, divided by any quanity as a consequent, gives the ratio of that antecedent to the consequent.

Thus the ratio of A to B is $\frac{A}{B}$, but the ratio of B to A is $\frac{B}{A}$; and, in numbers, the ratio of 12 to 4 is $\frac{12}{4} = 3$, or triple; but the ratio of 4 to 12 is $\frac{4}{12} = \frac{1}{3}$, or subtriple.

The quantities thus compared must be of the same kind; that is, such which, by multiplication, may be made to exceed one the other; or as these quantities are said to have a ratio between them, which, being multiplied, may be made to exceed one another. Thus a line, how short soever, may be multiplied, that is, produced so long as, to exceed in length any given right line, and consequently these may be compared together, and the ratio expressed; but as a line can never, by any multiplication whatever, be made to have breadth, that is, to be made equal to a superficies, how small soever; these can therefore never be compared together, and consequently have no ratio or respect one to another, according to quantity: that is, as to how often the one contains, or is contained in, the other. See PROPORTION.

RATION, a certain allowance which is given in bread, &c. or forage, when troops are on service, for an officer or soldier.

Complete ration of the small species.

Flour, or bread -	$1\frac{1}{2}$ lbs.
Beef - - -	1
or pork - - - -	$\frac{1}{2}$
Peas - - - -	$\frac{1}{4}$ pint
Butter, or cheese -	1 oz.
Rice - - - - -	1 oz.

When the small species are not issued, $1\frac{1}{2}$ lbs. of flour or bread, with $1\frac{1}{2}$ lbs. of beef, or 10 oz. of pork, forms a complete ration; or 3 lbs. of beef, or 2 lbs. of cheese, or half a pound of rice, forms a complete ration.

The deductions to be taken for provisions from the pay of officers, non-commissioned officers, or men, are the same for all ranks, and in all corps, under the like circumstances of service, when serving out of Great Britain, on stations where provisions are supplied by the public; also, when embarked in transports or other vessels, (except when serving as marines;) also when prisoners of war are maintained at the expence of Great Britain; also when in general hospitals, whether at home or abroad, a deduction of sixpence per day.

A deduction of threepence halfpenny from the pay of every non-commissioned officer and private in Jamaica, in New South Wales, or Gibraltar. Non-commissioned officers and soldiers serving as marines shall not be liable to any deduction from their full pay on account of provisions.

Ration for a horse on home service in 1796, 14 lbs. of hay, 10 lbs. of oats, 4 lbs. of straw, for which a stoppage is made of sixpence.

The French use the same term, viz. *ration de foin*, a ration of hay; *double ration*, double ration; *demi-ration*, a half-ration.

RATIONAL is applied to integral, fractional, and mixt numbers; thus we say, rational fraction, rational integer, and rational mixt number.

Rational is applied to the true horizon, in opposition to the sensible or apparent one.

RATIONALE, a solution, or account of the principles of some opinion, action, hypothesis, phænomenon, or the like.

RATLINES, or, as the seamen call them, RATLINS, those lines which make the ladder-steps to get up the shrouds and futtocks, hence called the ratlins of the shrouds.

RATTLE-SNAKE. See CROTALUS.

RAVELIN, in fortification, was antiently a flat bastion, placed in the middle of a curtin; but now a detached work composed only of two faces, which make a saliant angle, without any flanks, and raised before the curtin on the counterscarp of the place. A ravelin is a triangular work, resembling the point of a bastion with the flanks cut off. See FORTIFICATION.

Its use before a curtin is, to cover the opposite flanks of the two next bastions. It is used also to cover a bridge, or a gate, and is always placed without the moat. There are also double ravelins that serve to cover each other; they are said to be double when they are joined by a curtin.

RAVEN. See CORVUS.

RAUWOLFIA, a genus of the pentandria monogynia class of plants, the corolla of which consists of a single funnel-fashioned petal, with a large limb, divided into five lanceolated segments; the fruit is a succulent berry, with two seeds. There are four species, trees of South America.

RAY, a beam of light emitted from a radiant or luminous body. See OPTICS.

RAYS OF LIGHT, *colour and heat of*. Dr. Herschel had been employed in making observations on the sun by means of telescopes. To prevent the inconvenience arising from the heat, he used coloured glasses; but these glasses, when they were deep enough coloured to intercept the light, very soon cracked and broke in pieces. This circumstance induced him to examine the heating power of the different coloured rays. He made each of them in its turn fall upon the bulb of a thermometer, near which two other thermometers were placed to serve as a standard. The number of degrees which the thermometer exposed to the coloured ray rose above the other two thermometers, indicated the heating power of that ray. He found that the most refrangible rays have the least heating power; and that the heating power gradually increases as the refrangibility diminishes. The violet ray therefore has the smallest heating power, and the red ray the greatest. Dr. Herschel found that the heating power of the violet, green, and red rays, are to each other as the following numbers:

Violet = 16
Green = 22.4
Red = 55

It struck Dr. Herschel as remarkable, that the illuminating power and the heating power of the rays follow such different laws. The first exists in greatest perfection in the middle of the spectrum, and diminishes as we approach either extremity; but the second increases constantly from the violet end, and is greatest at the red end. This led him to suspect that perhaps the heating power does not stop at the end of the visible spectrum, but is continued beyond it. He placed the thermometer completely beyond the boundary of the red ray, but still in the line of the spectrum; and it rose still higher than it had done when exposed to the red ray. On shifting the thermometer still farther, it continued to rise; and the rise did not reach its maximum till the thermometer was half an inch beyond the utmost extremity of the red ray. When shifted still farther, it sunk a little; but the power of heating was sensible at the distance of $1\frac{1}{2}$ inch from the red ray.

These important experiments have been lately repeated and fully confirmed by sir Henry Englefield, in the presence of some very good judges. The apparatus was very different from that of Dr. Herschel, and contrived on purpose to obviate certain objections which had been made to the conclusions drawn by that illustrious philosopher. The bulbs of the thermometers used were mostly blackened. The following table exhibits the result obtained in one of these experiments:

Thermometer in the blue ray rose in	-	3′	from 55°	to 56°
green		3	54	58
yellow		3	56	62
full red		$2\frac{1}{2}$	56	72
confines of red		$2\frac{1}{2}$	58	$73\frac{3}{4}$
beyond the visible light		$2\frac{1}{2}$	61	79

The thermometer with its bulb blackened, rose much more when placed in the same circumstances, than the thermometer whose bulb was either naked or whitened with paint. This will be apparent from the following table:

		Time.	from	To
Red ray - -	Black therm.	3′	58°	61°
	White therm.		55	58
Dark - - -	Black therm.	3	59	64
	White therm.		58	$58\frac{1}{4}$
Confines of red	Black therm.	3	59	71
	White therm.		$57\frac{1}{2}$	$60\frac{1}{2}$

Both Dr. Herschel and sir Henry Englefield take notice of a faint blush of red of a semi-oval form, visible when the rays beyond the red end of the spectrum were collected by a lens.

From these experiments it seems to follow, that there are rays emitted from the sun, which produce heat, but have not the power of illuminating; and that these are the rays which produce the greatest quantity of heat. Consequently caloric is emitted from the sun

§

in rays, and the rays of caloric are not the same with the rays of light.

On examining the other extremity of the spectrum, Dr. Herschel ascertained that no rays of caloric can be traced beyond the violet ray. He had found, however, as Senebier had done before him, that all the coloured rays of the spectrum have the power of heating: it may be questioned therefore whether there are any rays which do not warm. The coloured rays must either have the property of exciting heat as rays of light, or they must derive that property from a mixture of rays of caloric. If the first of these suppositions was true, light ought to excite heat in all cases; but it has been long known to philosophers that the light of the moon does not produce the least sensible heat, even when concentrated so strongly as to surpass, in point of illumination, the brightest candles or lamps, and yet these produce a very sensible heat. Here then are rays of light which do not produce heat; rays, too, composed of all the seven prismatic coloured rays. We must conclude, from this well-known fact, that rays of light do not excite heat; and consequently that the coloured rays from the sun and combustible bodies, since they excite heat, must consist of a mixture of rays of light and rays of caloric. That this is the case was demonstrated long ago by Dr. Hooke, and afterwards by Scheele, who separated the two species from each other by a very simple method. If a glass mirror is held before a fire, it reflects the rays of light, but not the rays of caloric; a metallic mirror, on the other hand, reflects both. The glass mirror becomes hot; the metallic mirror does not alter its temperature. If a plate of glass is suddenly interposed between a glowing fire and the face, it intercepts completely the warming power of the fire, without causing any sensible diminution of its brilliancy; consequently it intercepts the rays of caloric, but allows the rays of light to pass. If the glass is allowed to remain in its station till its temperature has reached its maximum, in that situation it ceases to intercept the rays of caloric, but allows them to pass as freely as the rays of light. This curious fact, which shews us that glass only intercepts the rays of caloric till it is saturated with them, was discovered long ago by Dr. Robison, professor of natural philosophy in the university of Edinburgh. These facts are sufficient to convince us that the rays of light and of caloric are different, and that the coloured rays derive their heating power from the rays of caloric which they contain. Thus it appears that solar light is composed of three sets of rays, the colorific, the calorific, and the deoxidizing.

The rays of caloric are refracted by transparent bodies just as the rays of light. We see, too, that, like the rays of light, they differ in their refrangibility; that some of them are as refrangible as the violet rays, but that the greater number of them are less refrangible than the red rays. Whether they are transmitted through all transparent bodies has not been ascertained; neither has the difference of their refraction in different mediums been examined. We are certain, however, that they are transmitted and refracted by all transparent bodies which have been employed as burning-glasses. Dr. Herschel has also proved, by experiment, that it is not only the caloric emitted by the sun which is refrangible, but likewise the rays emitted by common fires, by candles, by hot iron, and even by hot water.

The rays of caloric are reflected by polished surfaces in the same manner as the rays of light. This was lately proved by Herschel; but it had been demonstrated long before by Scheele, who had even ascertained that the angle of their reflection is equal to the angle of their incidence. Mr. Pictet also had made a set of very ingenious experiments on this subject, about the year 1790, which led to the same conclusion. He placed two concave mirrors of tin, of nine inches focus, at the distance of twelve feet two inches from one another. In the focus of one of them he placed a ball of iron two inches in diameter, heated so as not to be visible in the dark; in the other was placed the bulb of a thermometer. In six minutes the thermometer rose 22°. A lighted candle, which was substituted for the ball of iron, produced nearly the same effect. In this case both light and heat appeared to act. In order to separate them, he interposed between the two mirrors a plate of clear glass. The thermometer sunk in nine minutes 14°; and when the glass was again removed, it rose in seven minutes about 12°; yet the light which fell on the thermometer did not seem at all diminished by the glass. Mr. Pictet therefore concluded, that the caloric had been reflected by the mirror, and that it had been the cause of the rise of the thermometer. In another experiment, a glass matrass was substituted for the iron ball, nearly of the same diameter with it, and containing 2044 grains of boiling water. Two minutes after a thick screen of silk, which had been interposed between the two mirrors, was removed, the thermometer rose from 47° to $50\frac{1}{2}$, and descended again the moment the matrass was removed from the focus.

The mirrors of tin were now placed at the distance of 90 inches from each other; the matrass with the boiling water in one of the foci, and a very sensible air-thermometer in the other, every degree of which was equal to about $\frac{1}{11}$ of a degree of Fahrenheit. Exactly in the middle space between the two mirrors there was placed a very thin common glass mirror, suspended in such a manner that either side could be turned towards the matrass. When the polished side of this mirror was turned to the matrass, the thermometer rose only 0.5°; but when the side covered with tin foil, and which had been blackened with ink and smoke, was turned towards the matrass, the thermometer rose to 3.5°. In another experiment, when the polished side of the mirror was turned to the matrass, the thermometer rose 3°, when the other side 9.2°. On rubbing off the tin foil, and repeating the experiment, the thermometer rose 18°. On substituting for the glass mirror a piece of thin white pasteboard of the same dimensions with it, the thermometer rose 10°.

As the rays of light and of caloric emitted by the sun accompany each other, it cannot be doubted that they move with the same velocity. The rays of caloric, therefore, move at the rate of almost 200,000 miles in a second. This is confirmed by an experiment of Mr. Pictet. He placed two concave mirrors at the distance of 69 feet from each other; the one of tin as before, the other of plaister gilt, and 18 inches in diameter. Into the focus of this last mirror he put an air-thermometer, and a hot bullet of iron into that of the other. A few inches from the face of the tin mirror there was placed a thick screen, which was removed as soon as the bullet reached the focus. The thermometer rose the instant the screen was removed, without any perceptible interval; consequently the time which caloric takes in moving 69 feet is too minute to be measured. We see at once that this must be the case when we recollect that caloric moves at the rate of 200,000 miles in a second.

The velocity of caloric being equal to that of light, its particles must be equally minute. Therefore neither the addition of caloric nor its abstraction can sensibly affect the weight of bodies. As this follows necessarily as a consequence from Dr. Herschel's experiments, was it possible to prove by experiment that caloric affects the weight of bodies, the theory founded on Dr. Herschel's discoveries would be overturned: but such deductions have been drawn from the experiments of De Luc, Fordyce, Morveau, and Chaussier. According to these philosophers, bodies become absolutely lighter by being heated. The experiment of Fordyce, which seems to have been made with the greatest care, was conducted in the following manner:

He took a glass globe three inches in diameter, with a short neck, and weighing 451 grains; poured into it 1700 grains of water from the New River, London, and then sealed it hermetically. The whole weighed $2150\frac{11}{12}$ grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of snow and salt till some of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be $\frac{1}{60}$ of a grain heavier than before. This was repeated exactly in the same manner five different times; at each, more of the water was frozen, and more weight gained. When the whole water was frozen, it was $\frac{3}{16}$ths of a grain heavier than it had been when fluid. A thermometer applied to the globe stood at 10°. When allowed to remain till the thermometer rose to 32°, it weighed $\frac{2}{16}$ths of a grain more than it did at the same temperature when fluid. It will be seen afterwards, that ice contains less caloric than water of the same temperature with it. The balance used was nice enough to mark $\frac{1}{1600}$th part of a grain.

This subject had attracted the attention of Lavoisier, a philosopher distinguished by the uncommon accuracy of his researches. His experiments, which were published in the Memoirs of the French Academy for 1783, led him to conclude that the weight of bodies is not altered by heating or cooling them, and consequently that caloric produces no sensible change on the weight of bodies. Count Rumford's experiments on the same subject, which were made about the year 1797, are perfectly decisive. He repeated the experiment of Dr. Fordyce with the most scrupulous caution; and by a number of the most ingenious contrivances, demonstrated, that neither the addition nor the abstraction of caloric makes any sensible alteration in the weight of bodies.

Caloric not only possesses the velocity of light, but agrees with it also in another property no less peculiar. Its particles are never found cohering together in masses; and whenever they are forcibly accumulated, they fly off in all directions, and separate from each other with inconceivable rapidity. This property necessarily supposes the existence of a mutual repulsion between the particles of caloric.

Thus it appears that caloric and light resemble each other in a great number of properties. Both are emitted from the sun in rays, with the velocity of 200,000 miles in a second; both of them are refracted by transparent bodies, and reflected by polished surfaces; both of them consist of particles which mutually repel each other, and which produce no sensible effect upon the weight of other bodies. They differ, however, in this particular; light produces in us the sensation of vision; caloric, on the contrary, the sensation of heat.

Upon the whole, we are authorized by the above statement of facts, to conclude, that the solar light is composed of three distinct substances, in some measure separable by the prism on account of the difference of their refrangibility. The calorific rays are the least refrangible, the deoxidizing rays are most refrangible, and the colorific rays possess a mean degree of refrangibility. Hence the rays in the middle of the spectrum have the greatest illuminating power, those beyond the red end the greatest heating power, and those beyond the violet end the greatest deoxidizing power: and the heating power on the one hand, and the deoxidizing power on the other, gradually increase as we approach that end of the spectrum where the maximum of each is concentrated. These different bodies resemble each other in so many particulars, that the same reasoning respecting refrangibility, reflexibility, &c may be applied to all; but they produce different effects upon those bodies on which they act. Little progress has yet been made in the investigation of these effects; but we may look forward to this subject as likely to correct many vague and unmeaning opinions which are at present in repute among philosophers.

RAZOR-BILL. See Alka.

REACH, in the sea language, signifies the distance between any two points of land, lying nearly in a right line.

RE-ACTION, in physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change its state whether of motion or rest. See Motion.

REALGAR, a mineral found in Sicily and various parts of Germany. It is either massive or crystallized. The primitive form of the crystal is an octahedron with scalene triangles, and it commonly appears in 4, 6, 8, 10, or 12 sided prisms, terminated by four-sided summits. Colour red. Streak yellowish-red. Specific gravity 3.338. It is electric per se, and becomes negatively electric by friction. Before the blowpipe it melts easily, burns with a blue flame, and soon evaporates. It is also the old name for a sulphuret of arsenic, found native in different parts of Europe. It has a scarlet colour, and is often crystallized in transparent prisms. Its specific gravity is 3.2. It is composed of 80 parts of arsenic, and 20 of sulphur, and it is sometimes used as a part.

REAR, a term frequently used in composition, to denote something behind, or backwards, in respect of another, in opposition to van: thus, in a military sense, it is used for the hind part of an army, in opposition to the front, for the rear-guard, rear half-files, rear-line, rear-rank, and rear-admiral.

RE-ATTACHMENT, a second attachment of him that was formerly attached and dismissed the court without day, as by the not coming of the justices, or some such casualty.

REAUMURIA, a genus of the class and order polyandria pentagynia. The calyx is six-leaved; petals five; caps. one-celled, five-valved, many-seeded. There is one species, an annual of Egypt.

REBATE, or Rebatement, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

REBELLION, taking up arms traitorously against the king, be it by natural subjects, or by others once subdued. See Riot.

REBUTTER, is the answer of the defendant to the plaintiff's sur-rejoinder.

RECAPITULATION, in oratory, &c. is a summary, or a concise and transient enumeration, of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

RECAPTION. Where one has deprived another of his property, the owner may lawfully claim and retake it wherever he happens to find it, so that it shall be not in a riotous manner, or attended with any breach of the peace.

RECEIPTS, are acknowledgments in writing of having received a sum of money or other value. A receipt is either a voucher for an obligation discharged or one incurred Receipts for money above 40*s.* must be on stamps: but on the back of a bill of exchange or promissory note which is already stamped, is good without a farther duty. Writing a receipt on a stamp of greater value than the law requires, incurs no penalty, and the receipt is good; but if on a stamp of a lower value, or on unstamped paper, then a receipt is no discharge, and incurs a penalty. See Stamp.

RECEIVER, in pneumatics, a glass vessel for containing the thing on which an experiment in the air-pump is to be made. See Pneumatics.

Receiver, in chemistry, a vessel of earth, glass, &c. for receiving any distilled liquor.

Receiver. Receiving stolen goods, knowing them to be stolen, is a high misdemeanour at the common law; and by several statutes is made felony and transportation; and in some particular instances, felony without benefit of clergy.

Receiver also signifies an officer, of which there are several kinds, denominated from the particular matters they receive, the places where, or the persons from whom, &c. 1. Receiver of the fines is an officer appointed to receive the money of such persons as compound with the king, upon original writs sued out of chancery. 2. Receiver-general of the duchy of Lancaster is an officer belonging to the duchy-court, who collects all the revenues, fines, forfeitures, and assessments, within that duchy. 3. Receiver-general of the public revenue, is an officer appointed in every county, to receive the taxes granted by parliament, and remit the money to the treasury.

RECIPE, in medicine, a prescription or remedy, to be taken by a patient; so called because always beginning with the word recipe, *i. e.* take; which is generally denoted by the abbreviature ℞.

RECIPIANGLE, or Recipient angle, a mathematical instrument, serving to measure re-entering and saliant angles, especially in fortification.

It usually consists of two arms, or rulers, AC, and BC (Plate Miscel. fig. 197) riveted together at C, and capable of being opened and closed, like a sector. To take an angle with it, they lay the centre of a protractor over the joint C, and apply its diameter to one of the rulers; then the degrees cut by the edge of the other ruler, shew the quantity of the angle.

There are other forms of this instrument: that represented fig. 198, has a graduated circle, by which the angles may be readily measured by its index; and fig. 199, is another kind composed of four equal rulers of brass, riveted together by their ends, so as to form a parallelogram; and on one of the rulers is fixed a graduated semicircle, which measures the opposite angle of the parallelogram, by means of one of the rulers produced so as to serve instead of an index.

RECIPROCAL terms, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

Reciprocal figures, in geometry, those which have the antecedents and consequents of the same ratio, in both figures. Thus, (Plate Miscel. fig. 200,) $A:B::C:D$: or $12:4::9:3$; that is, as much as the side A, in the first rectangle, is longer than B, so much deeper is the side C, in the second rectangle, than the side D in the first; and, consequently, the greater length of the one is compensated by the greater breadth or depth of the other; for as the side A is $\frac{1}{4}$ longer than C, so B is $\frac{1}{4}$ longer than D, and the rectangles of course equal; that is, $A + D = B \times C$, or $12 \times 3 = 4 \times 9 = 36$.

This is the foundation of that capital theorem, viz. that the rectangle of the extremes is always equal to that of the means; and, consequently, the reason of the rule of three.

Hence it follows, that if any two triangles, parallelograms, prisms, parallelopipeds, pyramids, cones, or cylinders, have their bases and altitudes reciprocally proportional, those two figures or solids are equal to each other; and, vice versa, if they are equal, then their bases and altitudes are reciprocally proportional. See Triangle, Parallelogram, &c.

Reciprocal proportion, in arithmetic, is when, in four numbers, the fourth is less than the second, by so much as the third is greater than the first; and vice versa.

This is the foundation of the inverse, or indirect, rule of three: thus, $4:10::8:5$.

It is applied also to quantities which, being multiplied together, produce unity. Thus $\frac{1}{x}$ and x, y and $\frac{1}{y}$, are reciprocal quantities, beause $\frac{1}{x} \times x = \frac{x}{x} = 1$, and $\frac{1}{y} \times y = \frac{y}{y} = 1$.

RECITATIVO, or Recitative, in mu-ic, a kind of singing, that differs but little ro.n ordinary pronunciation, such as that in which the several parts of the liturgy are re-earsed in cathedrals; or that in which the ctors commonly deliver themselves on the heatre at the opera, when they are to express ome action or passion, to relate some event, r reveal some design. Notwithstanding this ort of composition is noted in true time, the erformer is at liberty to alter the bars of neasure, and make some long and others hort, as his subject requires; hence the horough-bass to the recitative is usually laced below the other, to the end that he, who is to accompany the voice, may rather bserve and follow the singer, than the person hat beats the time.

RECKONING, or a Ship's Reckon-ng, in navigation, is that account by which t any time it may be known where the ship , and on what course or courses she is to teer in order to gain her port; and that ac-ount taken from the log-board is called the ead-reckoning. See Navigation.

RECLINER, or Reclining dial. See Dialling.

RECOGNISANCE, is an obligation of ecord, which a man enters into before some ourt of record, or magistrate duly autho-zed, with condition to some particular act; s to appear at the assizes or quarter-sessions, o keep the peace, &c.

RECOIL, or Rebound, the starting back-ard of a fire-arm, after an explosion. Mer-nnus tells us, that a cannon 12 feet in length, eighing 6400 lb. gives a ball of 24 lb. an uni-orm velocity of 640 feet per second. Putting, herefore, $W = 6400$, $w = 24$, $V = 640$, and $= $ the velocity with which the cannon re-oils; we shall have (because the momenta of he cannon and ball are equal) $Wv = wV$: and $v = \frac{wV}{W} = \frac{24 \times 64}{6400} = 2, 4$; that is, it ould recoil at the rate of $2\frac{4}{10}$ feet per second, free to move.

RECORD. An act committed to writing any of the king's courts, during the term herein it is written, is alterable, being no ecord; but that term once ended, and the act ly enrolled, it is a record, and of that redit which admits of no alteration or proof o the contrary.

RECORDARE facias, a writ directed to e sheriff, to remove a cause out of an in-rior court, into the king's-bench or common-eas.

RECORDER, a person whom the mayor nd other magistrates of a city or corporation sociate to them, for their better direction in atters of justice, and proceedings in law; n which account this person is generally a ounsellor, or other person well skilled in the w. The recorder of London is chosen by e lord-mayor and aldermen; and, as he is ld to be the mouth of the city, he delivers e judgment of the courts, and records and rtifies the city customs.

RECOVERY, in law, is obtaining any ing by judgment or trial at law.

A recovery resembles a fine so far as being action real or fictitious, and in that lands are recovered against the tenant of the freehold, and an absolute fee-simple is vested in the recoverer; but it is carried on through every stage of proceeding, instead of being compromised like a fine. See Fine.

This invention we owe to the ingenuity of the ecclesiastics, to evade the statute of mortmain, which prohibited them from purchasing or receiving, under pretence of a free gift, any lands or tenements whatsoever; and as judgment was given for religious houses, they were presumed to have recovered the lands by sentence of law, on a supposed prior title, and were held not to come within the statute. The convenience of those recoveries was soon discovered, and made use of by lay persons as a common mode of transferring lands; but the want of moderation on the part of the ecclesiastics, in their frequent recourse to feigned recoveries, was such as to call for parliamentary interference, and gave rise to the act in the reign of Edward the First, called the statute of Westminster; which enacts, that in all cases where ecclesiastical persons recovered lands by default, a jury should try the right; and if the demandants were found to have no title, the land should be forfeited to the lord of the fee, according to the statute of mortmain.

This act threw the recoveries into disuse, till they were resumed as a mode of evading the strictness of the statute de donis conditionalibus, which lays a general restraint on alienation. The people made many attempts to procure a repeal of this statute, but in vain; but as the inconveniences were manifest, the judges always endeavoured to contrive means of evading it; and it was decided in a case in the reign of Edward IV. that a common recovery suffered by a tenant intail, should operate as an effectual bar to his estate tail, and to all remainders and reversions depending thereon; by which means tenants in tail are now enabled to dispose of their estates, or convert them into estates in fee-simple; and it may be suffered of all things, whereof a writ of covenant may be brought for the purpose of levying a fine. There are three persons required to form a recovery; the demandant, tenant, and vouchee. The demandant is he who brings the writ of entry; the tenant is he against whom the writ is brought; and the vouchee is he whom the tenant vouches and calls to warranty; but this may be better understood by supposing John Jacobs to be tenant of the freehold, and desirous of suffering a recovery to cut off all entails and reversions, and to convey the estate in fee-simple to James Jenkins. Jenkins sues out a writ of precipe quod reddat, as in the case of a fine, and charges that the defendant has no title, but came into possession after Hugh Hunt had turned the plaintiff out of it. The proceedings are made up on the recovery-roll, in which the writ and complaint of the demandant are recited; the tenant then appears and calls upon one Charles Browning, who is supposed at the original purchase to have warranted the title to the tenant, and who is denominated the vouchee: the vouchee then appears, is impleaded, and defends the the title. Jenkins, the demandant, craves leave to imparl, which is granted; the plaintiff then returns into court, but the vouchee disappears and makes default; judgment is of course given for Jenkins, and Jacobs is to recover the value of the land from Charles Browning, as he lost them through his default. But on enquiry, it is always found that Browning (who is merely an officer of the court, and denominated the common vouchee, from being always vouched), has no lands, so that Jacobs, now called the recovree, has but a nominal recompence; and the plaintiff, who is now recoverer, has the lands vested in him by judgment of the court, and seisin delivered by the sheriff.

A recovery is sometimes with double or treble voucher, or even more if necessary. And, indeed, a double voucher is the most common, by first conveying an estate to any third person, against whom the writ is issued, he then vouches the tenant in tail who vouches over the common vouchee; for if the recovery is had immediately against the tenant in tail, it bars only such estate in the premises of which he is then actually seized; but if the recovery is had against a third person, and the tenant in tail is the first vouchee, it bars every latent right and interest which he may have in the lands recovered. If an infant suffers a recovery in person, he may reverse it, but then the writ of error must be brought during his minority. Sometimes, though but seldom, the court permits the infant to appear by guardian, where the recovery is of manifest advantage to the infant; and when this has been allowed by the judges, the infant cannot set it aside; but if it is to the prejudice of the infant, he has a remedy by action against the guardian. This appears from several cases. If the infant appears by attorney, he may reverse the recovery after he is of age, because it may be here discovered by trial whether the warrant of attorney was made by him while an infant. A married woman joining with her husband in suffering a recovery, will bar her remainder; because as she is examined privately as to her consent, it takes away the presumption in law that it is done by the compulsion of her husband.

All persons have power to suffer a recovery except the king (for if he does, he must either be tenant or vouchee, and in both cases the plaintiff must count against him, which the law does not allow), infants, persons non compos, and women who are possessed of dower; who are prohibited by the statute of 11 Henry VII. c. 20, which enacts that a recovery suffered by any woman of lands settled on her by her husband, or settled on her husband and her by any of his ancestors, shall be void.

The effect of common recoveries may appear to be an absolute bar not only of all estates tail, but of remainders and reversions expectant on the determination of such estates. So that a tenant in tail may convey lands in tail to the recoverer, free and discharged of all conditions and appointments in tail, and of all remainders and reversions. But as is before mentioned, a woman possessed of dower is prevented by the statute; and by the statute of 11 Eliz. c. 8, no tenant for life of any sort can suffer a recovery, so as to bind them in remainder or reversion. For which reason, if there is a tenant for life with remainder in tail, and other remainders over, and the tenant for life is desirous to suffer a valid recovery, either he or the tenant to the precipe must vouch the remainder-man in tail. It is an essential part of a recovery, that the tenant to the precipe should be actually seised of the freehold; but by 14 Geo. II. though the legal freehold should be vested in lessees, yet those who are intitled to the next freehold estate in remainder or reversion may make a good tenant to the precipe; and though the deed or fine which creates such tenant should be subsequent to the judgment of recovery, if it is in the same term, the recovery is valid; and that though the recovery itself does not appear to be entered, or not regularly entered on record: yet the deed to make a tenant to the precipe and declare the uses of the recovery, with twenty years possession, shall be sufficient evidence of the recovery. If a recovery is levied without any good consideration or the uses declared, they only enure to the use of him who levies them; and if there is a consideration, yet as the most usual fine, sur cognizance de droit comme ces, &c. conveys an absolute estate without limitations, these conveyances could not be made to answer the purposes of family settlements (wherein a variety of uses and designations is often necessary), unless their force and effect were made subject to the direction of more complicated deeds. These deeds, if made previous to the judgment, are called deeds to lead the uses; if subsequent, to declare them.

RECTANGLE, in geometry, the same with a right-angled parallelogram.

RECTANGLED, Rectangular, or Right-angled, appellations given to figures and solids which have one or more right angles: thus a triangle with one right angle, is termed a rectangled triangle; also parallelograms with right angles, squares, cubes, &c. are rectangular. Solids, as cones, cylinders, &c. are also said to be rectangular with respect to their situation, when their axes are perpendicular to the plane of the horizon.

RECTIFICATION, in geometry, is the finding a right line, equal in length to a curve. See the article Curve.

The rectification of curves is a branch of the higher geometry, where the use of the inverse method of fluxions is very conspicuous.

Case I. Let ACG, (Plate Miscel. fig. 201) be any kind of curve, whose ordinates are parallel to themselves, and perpendicular to the axis AQ. Then if the fluxion of the absciss AM is denoted by M*m*, or by C*n* (equal and parallel to M*m*), and *n*S, equal and parallel to C*r*, is the representation of the corresponding fluxion of the ordinate MC; then will the diagonal CS, touching the curve in C, be the line which the generating point *p* would describe, was its motion to become uniform at C; which line, therefore, truly expresses the fluxion of the space AC, gone over. See the article Fluxions.

Hence, putting AM $= x$, CM $= y$, and AC $= z$; we have $\dot{z} =$ CS $= \sqrt{Cn^2 + Sn^2} = \sqrt{\dot{x}^2 + \dot{y}^2}$; from which, and the equation of the curve, the value of z may be determined. Thus, let the curve proposed be a parabola of any kind, the general equation for which is $x = \frac{y^n}{a^{n-1}}$; and hence $\dot{x} = \frac{ny^{n-1}\dot{y}}{a^{n-1}}$, and therefore $\dot{z}\ (= \sqrt{\dot{y}^2 + \dot{x}^2}) = \sqrt{\dot{y}^2 + \frac{n^2y^{2n-2}\dot{y}^2}{a^{2n-2}}}$

$$= \dot{y} \times \left(1 + \frac{n^2y^{2n-2}}{a^{2n-2}}\right)^{\frac{1}{2}};$$ the fluent of which, universally expressed in an infinite series, is

$$y + \frac{n^2y^{2n-1}}{2n-1 \times 2a^{2n-2}} - \frac{n^4y^{4n-3}}{4n-3 \times 8a^{4n-4}} + \frac{n^6y^{6n-5}}{6n-5 \times 16a^{6n-6}} \text{ \&c.} = z.$$

Case II. Let all the ordinates of the proposed curve ARM, fig. 202, be referred to a centre C: then, putting the tangent RP (intercepted by the perpendicular CP) $= t$, the arch, BN, of a circle, described about the centre C, $= x$; and the radius CN (or CB) $= a$; we have $\dot{z} : \dot{y} :: y$ (CR) $: t$ (RP); and, consequently, $\dot{z} = \frac{\dot{y}y}{t}$: from whence the value of z may be found, if the relation of y and t is given. But, in other cases, it will be better to work from the following equation, viz. $\dot{z} = \sqrt{\dot{y}^2 + \frac{y^2\dot{x}^2}{a^2}}$, which is thus derived; let the right line CR be conceived to revolve about the centre C; then, since the celerity of the generating point R, in a direction perpendicular to CR, is to ($\dot{x}$) the celerity of the point N, as CR (y) to CN (a), it will therefore be truly represented by $\frac{y\dot{x}}{a}$; which being to ($\dot{y}$) the celerity in the direction of CR produced, as CB (s) : RP (t), it follows that $\frac{y^2\dot{x}^2}{a^2} : \dot{y}^2 :: s^2 : t^2$; whence, by composition, $\frac{y^2\dot{x}^2}{a^2} + \dot{y}^2 : \dot{y}^2 :: s^2 + t^2\ (y^2) : t^2$; therefore $\frac{y^2\dot{x}^2}{a^2} + \dot{y}^2 = \frac{y^2\dot{y}^2}{t^2}$, and consequently $\sqrt{\frac{y^2\dot{x}^2}{a^2} + \dot{y}^2}\ (= \frac{y\dot{y}}{t}) = \dot{z}$. Q. E. D.

Rectification, in chemistry, the repetition of a distillation or sublimation several times, in order to render the substance purer, finer, and freer from aqueous or earthy parts. See Distillation.

RECTILINEAR, in geometry, right-lined; thus figures whose perimeter consists of right lines, are said to be rectilinear.

RECTO, in law, a writ of right, which is of so high a nature, that whereas other writs in real actions are only to recover the possession of the land or tenements in question, which have been lost by our ancestors or ourselves; this aims to recover both the seisin which some of our ancestors or we had, and also the property of the hiring whereof the ancestor died not seised as of fee; and whereby are pleaded and tried both their rights together, viz. as well of possession as of property; so that if a man ever loses his cause upon this writ, either by judgment, or assize he is without remedy. Pract. Lib. 5.

Recto de advocatione ecclesiæ, a writ of right, lying where a man has a right of advowson, and the parson of the church dying, a stranger presents his clerk to the church; and he not having brought his action of quare impedit, nor darrein presentment, within six months, but suffered the stranger to usurp upon him.

Recto de dote, a writ of right of dower, which lies for a woman who has received part of her dower, and purposes to demand the remainder in the same town, against the heir, or his guardian if he is a ward.

Recto de dote unde nihil habet, a writ of right which lies in a case, where the husband having divers lands or tenements, has assured no dower to his wife, and she thereby is driven to sue for her thirds, against the heir or his guardian.

Recto quando dominus remisit, a writ of right, which lies in cases, where lands or tenements in the seigniory of any lord are in demand by a writ of right.

RECTOR, a term applied to several persons whose offices are very different; as, 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tythes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the house; and the jesuits give this name to the superiors of such of their houses as are either seminaries or colleges.

RECTORY, a parish church, parsonage, or spiritual living, with all its rights, tythes, and glebes.

RECTUM, in anatomy, the third and last of the large intestines. See Anatomy.

RECURVIROSTRA, in ornithology, a genus belonging to the order of grallæ. The bill is long, subulated, bent back, sharp and flexible at the point. The feet are webbed, and furnished with three toes forwards, and a short one behind. Mr. Latham notes of this genus three species, viz. the avosetta, or the one commonly known, the Americana, and the alba. This last, it is probable, has some affinity to the Americana. The recurvirostra avosetta is about the size of a lapwing in body, but has very long legs. The substance of the bill is soft, and almost membranous at its tip; it is thin, weak, slender, compressed horizontally, and incapable of defence or effort. These birds are variegated with black and white, and during the winter are frequent on the eastern shores of Great Britain. They visit also the Severn, and sometimes the pools of Shropshire. They feed on worms and insects, which they scoop out of the sand with their bills. They lay two eggs, white, with a greenish hue, and large spots of black, about the size of a pigeon's. They are found also in various parts of the continent of Europe, in Russia, Denmark, and Sweden, but they are not numerous. They are also found in Siberia, but oftener about the salt lakes of the Tartarian desert, and about the Caspian sea; likewise on the coasts of Picardy in France, in April and November, and at Orleans, but rarely. In breeding-time they are very plentiful on the coasts of Bas Poictou. They do not appear to wander further south in Europe than Italy. Whether from timidity or address, the avoset shuns snares, and is not easily taken. The American avoset is rather larger and longer than the last. The bill is similar, and its colour black; the forehead is dusky white; the head, neck, and upper part of the breast, are of a deep cream-colour; the lower parts of the neck behind white; the back is black, and the under parts from the breast pure white; the wings are partly black, partly white, and partly ash-coloured. These birds inhabit North America; and were found by Dampier in Sharks-bay, on the coast of New Holland. See Plate Nat. Hist. fig. 345.

The recurvirostra, or scolopax alba, is about 14 inches and a quarter long, its colour white, the inferior coverts of its wings duskish, its bill orange, its legs brown. Edwards remarks that the bill of this bird is bent upwards, as in the avoset: its bill black at the tip, and orange the rest of its length; all the plumage is white, except a tint of yellowish on the great quills of the wing and of the tail. Edwards supposes that the whiteness is produced by the cold climate of Hudsons-bay, from which he received it, and that they resume their brown feathers during the summer. It appears that several species of this bird have spread further into America, and have even reached the southern provinces.

A bird of this kind, Mr. Latham says, was sent from Hudsons-bay, and from the figure, has every appearance of an avoset. In Edwards's plate, however, the toes appear cloven to the bottom; a circumstance seeming to overturn the supposition, and only to be authenticated when other specimens shall have come under the eye of the well-informed naturalist.

RECUSANT, a person who refuses to go to church, and worship God after the manner of the church of England, as by law established; to which is annexed the penalty of 20*l.* a month for nonconformity. 23 Eliz. c. 1.

RED, in dyeing, is one of the five simple or mother colours. See DYEING.

RED-LEAD. See LEAD, *oxide of.*

RED-BOOK of the exchequer, an antient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellaneous treatises relating to the times before the Conquest.

REDDENDUM, in our law, is used substantively for the clause in a lease wherein the rent is reserved to the lessor. The proper place for it is next after the limitation of estate.

REDEMPTION, in law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon reimbursing the purchase-money with legal costs. Bargains wherein the faculty, or, as some call it, the equity, of redemption is reserved, are only a kind of pignorative contracts. A certain time is limited within which the faculty of redemption shall be exercised, and beyond which it shall not extend.

REDENS, REDANS, or REDANT, in fortification, a kind of work indented in form of the teeth of a saw, with saliant and re-entering angles, to the end that one part may flank or defend another. It is called saw-work, and indented work. Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expence of building bastions; as when they stand on the side of a river, a marsh, the sea, &c.

REDOUBT, or REDOUTE, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach, as also for the lodgings of corps de garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone-works, for the security of the neighbourhood; their face consists of from 10 to 15 fathoms, the ditch round them from 8 to 9 feet broad and deep, and their parapets have the same thickness.

REDUCT, or REDUIT, a military term signifying an advantageous piece of ground, entrenched and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to in case of a surprize.

REDUCTION, that rule by which numbers of different denominations are brought into one denomination. See ARITHMETIC.

REDUCTION *of a figure, design, or draught,* is the making a copy of it either larger or smaller than the original, still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction.

There are various methods of reducing figures, &c. The most easy is by means of the pentagraph, or parallelogram; but this has its defects. See PENTAGRAPH.

The best and most usual methods of reduction are as follows: 1. To reduce a figure, as ABCDE (Plate Miscel. fig. 203) into a less compass. About the middle of the figure, as z, pitch on a point, and from this point draw lines to its several angles A, B, C, &c. then drawing the line *ab* parallel to AB, *bc* parallel to BC, &c. you will have the figure *abcde* similar to ABCDE.

If the figure *abcde* had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as zD, zC, &c. and to draw lines, viz. DC, CB, &c. parallel to the sides *dc*, *cb*, &c.

2. To reduce a figure by the angle of proportion, suppose the figure ABCDE, (fig. 204) required to be diminished in the proportion of the line AB to *ab*, (fig. 205). Draw the indefinite line GH, (fig. 206) and from G to H set off the line AB. On G describe the arch HI. Set off the line *ab* as a chord on HI, and draw GI. Then with the angle IGH, you have all the measures of the figure to be drawn. Thus, to lay down the point *c*, take the interval BC, and upon the point G, describe the arch KL. Also on the point G, describe MN; and upon A, with the distance MN, describe an arch cutting the preceding one in *c*, which will determine the side *bc*. And after the same manner are the other sides and angles to be described. The same process will also serve to enlarge the figure.

3. To reduce a figure by a scale. Measure all the sides of the figure, as ABCDE, fig. 204, by a scale, and lay down the same measures respectively from a smallerscale in the proportion required.

4. To reduce a map, design, or figure, by squares. Divide the original into little squares; and divide a fresh paper of the dimensions required into the same number of squares, which are to be larger or less than the former, as the map is to be enlarged or diminished. This done, in every square of the second figure draw what you find in its correspondent one in the first.

REDUCTION, in metallurgy, is the bringing back metalline substances which have been changed into scoriæ or oxides, into their natural and original state of metals again. See CHEMISTRY.

REDUCTION, in surgery, denotes an operation by which a dislocated, luxated, or fractured bone, is restored to its former state or place.

REDUNDANT HYPERBOLA, is a curve of the higher kind, thus called because it exceeds the conic section of that name, in the number of its hyperbolical legs; being a triple hyperbola with six hyperbolical legs.

REDUPLICATION, in logic, a kind of condition expressed in a proposition indicating or assigning the manner in which the predicate is attributed to the subject. Hence reduplicative propositions are such wherein the subject is repeated with some circumstance or condition, thus: Men, as men, are rational; Kings, as kings, are subject to none but God.

REED. See ARUNDO.

REEF, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so much wind; which contracting or taking up the sail they call a reef, or reefing the sail; so also when a top-mast is sprung, as they call it, that is, when it is cracked, or almost broken in the cap, they cut off the lower piece that was nearly broken off, and setting the other part, now much shorter, in the step again, they call it a reefed top-mast.

REEL, in the manufactories. There are various kinds of reels, some very simple, others very complex. Of the former kinds those most in use are: 1. A little reel held in the hand, consisting of three pieces of wood, the biggest and longest whereof (which does not exceed a foot and a half in length, and a quarter of an inch in diameter) is traversed by two other pieces disposed different ways. 2. The common reel, or windlass, which turns upon a pivot, and has four flights traversed by long pins or sticks, whereon the skain to be reeled is put, and which are drawn closer or opened wider according to the skain. A representation of the common reel may be seen in Plate Miscel. fig. 207, where A is the bench or seat of the reel, B the two uprights; C the arms of the reel, its arbor turning, and hitching its little lantern of four notches in the teeth of the wheel; D two wheels, the upper one of which moves the lower by means of a pinion; E a hammer, the handle whereof is lowered by a peg at the bottom of the lower wheel; F a cord which is rolled round the axle of the lower wheels, and supports a weight which stops after a certain number of turns, to regulate the work-woman.

REELING, in the manufactories, the winding of thread, silk, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins or quills, to use them in the manufacture of different stuffs, as thread, silks, cotton, &c.

RE-ENTRY, in law, signifies the resuming or retaking that possession which any one had lately foregone; as where a person makes a lease of lands to another, the lessor thereby quits the possession, and the lessee covenants that upon non-payment of the rent reserved, the lessor may lawfully re-enter.

REEVING, in the sea language, the putting a rope through a block; hence to pull a rope out of a block, is called unreeving.

REFINING, in general, is the art of purifying a thing; including not only the assaying or refining of metals, but likewise the depuration or clarification of liquors. Gold and silver may be refined by several methods, which are all founded on the essential properties of these metals, and acquire different names according to their kinds. Thus, for instance, gold having the property which no other metal, not even silver, has, of resisting the action of sulphur, of antimony, of nitrous acid, of marine acid, may be purified by these agents from all other metallic substances, and consequently may be refined. These operations are distinguished by proper names, as purification of gold by antimony, parting, concentrated parting, dry parting. In a similar manner, as silver has the property, which the imperfect metals have not, of resisting the action of nitre, it may be refined by this salt; but the term refining is chiefly applied to the purification of gold and silver by lead in the cupel. This is performed by the destruction, vitrification, and scorification, of all the extraneous and destructible metallic substances with which they are allayed.

As none but the perfect metals can resist the combined action of air and fire, without losing their inflammable principle and being changed into earthy or vitreous matters, incapable of remaining any longer united with substances in a metallic state, there is then a possibility of purifying gold and silver from all allay of imperfect metals merely by the action of fire and air, only by keeping them fused till all the allay is destroyed; but this purification would be very expensive, from the great consumption of fuel, and would be exceedingly tedious. Silver allayed with copper has been exposed longer than 60 hours to a glass-house fire without being perfectly refined; the reason of which is, that when a small quantity only of imperfect metal remains united with gold or silver, it is covered and protected from the action of the air, which is necessary for the combustion of the imperfect metals, as of all combustible matters.

This refining of gold and silver merely by the action of fire, which was the only method antiently known, was very long, difficult, expensive, and imperfect; but a much shorter and more advantageous method has been discovered. This method consists in adding to the allayed gold and silver a certain quantity of lead, and exposing afterwards this mixture to the action of the fire. Lead is one of the metals which loses most quickly and easily a sufficient quantity of its inflammable principle to cease to be in a metallic state; but, at the same time, this metal has the remarkable property of retaining, notwithstanding the action of the fire, enough of this same inflammable principle to be very easily melted into a vitrified and powerfully vitrifying matter, called litharge.

The lead then which is to be added to the gold and silver to be refined, or which happens naturally to be mixed with these metals, produces in their refining the following advantages: 1. By increasing the proportion of imperfect metals, it prevents them from being so well covered and protected by the perfect metals. 2. By uniting with these imperfect metals, it communicates to them a property it has of losing very easily a great part of its inflammable principle. 3. By its vitrifying and fusing property which it exercises with all its force upon the calcined and naturally refractory parts of the other metals, it facilitates and accelerates the fusion, the scorification, and the separation, of these metals. These are the advantages procured by lead in the refining of gold and silver.

The lead, which in this operation is scorified, and scorifies along with it the imperfect metals, separates from the metallic mass, with which it is then incapable of remaining united. It floats upon the surface of the melted mass, because, by losing part of its phlogiston, it loses also part of its specific gravity, and lastly it vitrifies.

These vitrified and melted matters accumulating more and more upon the surface of the metal while the operation advances, would protect this surface from the contact of air which is so absolutely necessary for the scorification of the rest, and would thus stop the progress of the operation, which could never be finished if a method had not been contrived for their removal. This removal of the vitrified matter is procured either by the nature of the vessel in which the melted matter is contained, and which being porous, absorbs and imbibes the scorified matter as fast as it is formed; or by a channel cut in the edge of the vessel, through which the matter flows out.

The vessel in which the refining is performed is flat and shallow, that the matter which it contains may present to the air the greatest surface possible. This form resembles that of a cup, and hence it has been called cupel. The furnace ought to be vaulted, that the heat may be applied upon the surface of the metal during the whole time of the operation. Upon this surface a crust of dark-coloured pellicle is continually forming. In the instant when all the imperfect metal is destroyed, and consequently the scorification ceases, the surface of the perfect metals is seen, and appears clean and brilliant. This forms a kind of fulguration or coruscation: by this mark the metal is known to be refined. If the operation is so conducted that the metal sustains only the precise degree of heat necessary to keep it fused before it is perfectly refined, we may observe that it fixes or becomes solid all at once in the very instant of the coruscation; because a greater heat is required to keep silver or gold in fusion when they are pure than when allayed with lead.

The operation of refining may be performed in small or in large quantities upon the same principles, but only with some differences in the management. As the refining of small quantities of perfect metals is performed in the same manner as these metals are assayed, the assay being only a very accurate refining, we refer to the article Assaying.

REFLECTION *of the rays of light*, in catoptrics, is their return, after approaching so near the surfaces of bodies, as to be repelled, or driven backwards. See Optics.

Reflector, a mirror or looking-glass. For the laws of reflexion see Optics; and for the method of silvering or foliating glass to make it reflect, see Foliating *of looking-glasses*. Vol. I. p. 758.

REFRACTION *of the rays of light*. See Optics.

Refraction, in astronomy, is an inflection of the rays of light proceeding from the heavenly bodies, in passing through the atmosphere, by which their apparent altitudes are increased. See Astronomy, Vol. I. page 171.

Refraction *in island crystal*. There is a double refraction in this substance, contrary ways, by which not only oblique rays are divided into two, and refracted into opposite parts, but even perpendicular rays are one-half refracted.

REFRANGIBILITY *of light*, the disposition of rays to be refracted. See Optics.

REGALIA, in law, the rights and prerogatives of a king; which, according to civilians, are six, viz. 1, the power of judicature; 2, the power of life and death; 3, the power of peace and war; 4, a right to such goods as have no owner, as waifs, estrays, &c. 5, assessments; and, 6, the coinage of money.

Regalia is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the cross, four several swords, &c.

REGARDANT, in heraldry, signifies looking behind; and is used for a lion, or other beast, with his face turned towards his tail. See Heraldry.

REGENT, one who governs a kingdom during the minority or absence of the king. In France, the queen-mother has the regency of the kingdom during the minority of the king, under the title of queen-regent.

Regent also signifies a professor of arts and sciences in a college, who has a set of pupils under his care; but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c. those of philosophy are rather called professors. The foreign universities are generally composed of doctors, professors, and regents.

REGIMEN, the regulation of diet, and in a more general sense, of all the non-naturals, with a view to preserve or restore health. See Materia Medica, article *Dietetics*.

Regimen, in grammar, that part of syntax or construction which regulates the dependancy of words, and the alterations which one occasions in another.

REGIMENT, a term applied to any body of troops: which, if cavalry, consists of one or more squadrons, commanded by a colonel; and, if infantry, of one or more battalions, each commanded in the same manner. The squadrons in cavalry regiments are divided, sometimes into six, and sometimes into nine troops. The battalions of British infantry are generally divided into ten companies, two of which are called the flanks; one on the right consisting of grenadiers, and another on the left formed of light troops. There is not, however, any established rule on this head; as both cavalry and infantry regiments differ according to the exigencies of service in time of war, or the principles of economy in time of peace. We are humbly of opinion, that every regiment of foot should consist of 2400 men, making three battalions of 800 each. The German regiments frequently consist of 2000 men; and the regiment of Picardy in the old French service had 6000. The French have made a distinction between the commanding officer of a regiment of cavalry, and the commanding officer of a regiment of infantry: the former was stiled mestre de camp; the latter colonel, as with us.

According to the establishment of the present French army, the term of regiment is confined to the cavalry and artillery, and the name of half-brigade is given to the infantry; so that chef de brigade, chief of brigade, corresponds with our colonel of a regiment of infantry. The denomination of colonel is still retained in the French cavalry.

With respect to the derivation of the word, it appears that the best etymology is from the French word régie, management, which comes from the Latin regere, to govern. Hence a regiment is said to be governed by a colonel. M. Beneton, a celebrated French etymologist, differs from this explanation. He traces it from the French régime, which signifies system, regimen, administration, and which is again derived from the Latin regimen, bearing the same import. In a physical acceptation of the term, régime (unde regimen) is used to express any body that is composed of several others. But this is mere conjecture on his part.

REGISTER, a public book, in which are entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact.

Of these there are several kinds; as, 1. Registers of deeds in Yorkshire and Middlesex, in which are registered all deeds, conveyances, wills, &c. that affect any lands or tenements in those counties, which are otherwise void against any subsequent purchasers, or mortgagees, &c. but this does not extend to any copyhold estate, nor to leases at a rack-rent, or where they do not exceed 21 years. The registered memorials must be ingrossed on parchment, under the hand and seal of some of the grantors or grantees, attested by witnesses who are to prove the signing or sealing of them, and the execution of the deed.

But these registers which are confined to two counties, are in Scotland general, by which the laws of North Britain are rendered very easy and regular. Of these there are two kinds; the one general, fixed at Edinburgh, under the direction of the lord-register; and the other kept in the several shires, stewartries, and regalities, the clerks of which are obliged to transmit the registers of their respective courts to the general register. No man in Scotland can have a right to any estate, but it must become registered within 40 days of his becoming seised thereof, by which means all secret conveyances are cut off. 2. Parish registers, are books in which are registered the baptisms, marriages, and burials, of each parish. The dissenters of all denominations register the births of their children at Dr. Williams's library in Red Cross street, Cripplegate.

Register is also used for the clerk or keeper of a register. Of these we have several, denominated from the registers they keep; as register of the high court of delegates; register of the arches court of Canterbury; register of the court of admiralty; register of the prerogative court; register of the garter, &c.

Register ships, in commerce, are vessels which obtain a permission either from the king of Spain, or the council of the Indies, to traffic in the ports of the Spanish West Indies, which are thus called from their being registered before they set sail from Cadiz for Buenos Ayres. Each of these permissions costs 30,000 pieces of eight; and by the tenor of the cedula, or permit, they are not to exceed 300 tons: but there is such a good understanding between the merchants and the council of the Indies, that ships of 5 or 600 tuns frequently pass unnoticed; and though the quantity and quality of the merchandize on board are always expressed, yet, by means of presents, the officers both in Spain and the Indies allow them to load and unload vastly more than the permission expresses.

Register, in printing, is disposing the forms on the press, so that the lines and pages printed on one side of the sheet fall exactly on those of the other.

Register, among letter-founders, is one of the inner parts of the mould in which the printing-types are cast. Its use is to direct the joining the mould justly together again, after opening it to take out the new-cast letter.

REGLETS, or Riglets, in printing, are thin slips of wood, exactly planed to the size of the body of the letter. The smaller sorts are placed between the lines of poetry; and both those and the larger are used in filling up short pages, in forming the whites or distances between the lines of titles, and in adjusting the distances of the pages in the chase so as to form register.

REGRATOR, or Regrater, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail; but the term is now used for one who buys any wares or victuals, and sells them again in the same market or fair, or within five miles round it. See Forestalling.

Regrator, is also used for one who furbishes up old moveables to make them pass for new. And masons who take off the outward surface of hewn stone, in order to whiten it, or make it look fresh again, are said to regrate.

REGULAR, denotes any thing that is agreeable to the rules of art: thus we say a regular building, verb, &c.

A regular figure in geometry is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle or square, as all others with more sides are called regular polygons.

All regular figures may be inscribed in a circle. A regular solid, called also a Platonic body, is that terminated on all sides by regular and equal planes, and whose solid angles are all equal.

The regular bodies are the five following: 1. The tetrahedron, which is a pyramid comprehended under four equal and equilateral triangles. 2. The hexahedron, or cube, whose surface is composed of six equal squares. 3. The octahedron, which is bounded by eight equal and equilateral triangles. 4. The dodecahedron, which is contained under twelve equal and equilateral pentagons. 5. The icosihedron, consisting of 20 equal and equilateral triangles. These five are all the regular bodies in nature. See Tetrahedron, &c.

Proportion of the five regular bodies inscribed in the same (circle from Peter Horigon. Cursus Math. vol. i. p. 779. and Barrow's Euclid, lib. xiii.):

The diameter of the sphere being 2,

The circumference of the greatest circle is - -	6.28318
Superficies of the greatest circle	3.14159
Superficies of the sphere -	12.56637
Solidity of the sphere -	4.18859
Side of the tetrahedron -	1.62299
Superficies of a tetrahedron -	4.6188
Solidity of a tetrahedron -	0.15132
Side of a cube or hexahedron -	1.1547
Superficies of the hexahedron	8.
Solidity of the hexahedron -	1.5396
Side of an octahedron - -	1.41421
Superficies of the octahedron -	6.9282
Solidity of the octahedron -	1.33333
Side of the dodecahedron -	0.71364
Superficies of the dodecahedron	10.51462
Solidity of the dodecahedron	2.78516
Side of the icosihedron -	1.05146
Superficies of the icosihedron	9.57454
Solidity of the icosihedron -	2.53615

If one of these five regular bodies was required to be cut out of the sphere of any other diameter, it will be, As the diameter of the sphere (2), is to the side of any one solid inscribed in the same (suppose the cube, 1.1547), so is the diameter of any one sphere (suppose 8), to 9.2376, the side of the cube inscribed in this latter sphere.

Let dr (Plate Miscel. fig. 208.) be the diameter of any sphere, and da $\frac{1}{3}$ of it $=ab=br$. Erect the perpendiculars ae, cf, and bg, and draw de, df, er, fr, and gr. Then will

1. re be the side of the tetrahedron.
2. df be the side of the hexahedron.
3. de be the side of the octahedron.
4. Cut de in extreme and mean proportion in h, and ch will be the side of the dodecahedron.
5. Set the diameter dr up, perpendicularly, at r; and from the centre c, to its top, draw the line cg, cutting the circle in g. Let fall the perpendicular gb, then is br the side of the icosihedron.

Regular *curves*, such as proceed gradually in the same geometrical manner with regard to their curvities. See Curve.

REGULATOR *of a watch*, the small spring belonging to the balance; serving to adjust its motions, and make it go faster or slower. See Clockwork.

REGULUS, in chemistry, an imperfect metallic substance that falls to the bottom of the crucible in the melting of ores, or impure metallic substances. The regulus is now understood to be the pure metal.

Regulus, in astronomy, a star of the first magnitude, in the constellation Leo; called also from its situation, cor leonis, or the lion's heart. See Astronomy.

REIN-DEER. See Cervus.

REJOINDER, in law, is the defendant's answer to the plaintiff's replication or reply. Thus, in the court of chancery, the defendant puts in an answer to the plaintiff's bill, which is sometimes also called an exception; the plaintiff's answer to this is called a replication, and the defendant's answer to that a rejoinder.

REJOINTING, in architecture, filling up the joints of the stones in buildings. This ought to be performed with the best mortar, as that of lime and cement; and sometimes with plaister, as in the joints of vaults.

RELATIVE TERMS, in logic, are words which imply a relation; such are master and servant, husband and wife, &c.

In grammar, relative words are those which answer to some other word foregoing, called the antecedent; such are the relative pronouns, qui, quæ, quod, &c. and in English, who, whom, which, &c. The word answering to these relatives is often understood as, I know whom you mean, for, I know (the person) whom you mean.

RELEASE, in law, is an instrument in writing, by which estates, rights, titles, entries, actions, and other things, are extinguished and discharged; and sometimes transferred, abridged, or enlarged; and in general, it signifies one person's giving up or discharging the right or action he has, or claims to have, against another, or his lands, &c.

A release may be either in fact or in law; a release in fact is where it is expressly declared, by the very words, as the act and deed of the party; and a release in law is that which acquits by way of consequence, as where a feme creditor takes the debtor to be her husband.

RELHANIA, a genus of the class and order syngenesia polygamia superflua. The calyx is imbricate, scariose; corollets of the ray many; pappus membranaceous; recept. chaffy. There are 16 species, herbs of the Cape.

RELIEF, in law, a certain sum of money which the tenant holding by knight's service, grand serjeantry, or other tenure (for which homage, or legal service, is due), and being at full age at the death of his ancestor, paid to his lord at his entrance.

RELIEVE, in a military sense, is to send off those men that are upon duty, and to bring others to take their place; thus, to relieve the guard, the trenches, &c. is to bring fresh men upon duty, and to discharge those who were upon duty before.

RELIEVO, and RELIEF, are terms applied to that mode of working in sculpture by which figures are made to project from the ground or body on which they are formed, and to which they remain attached. The same term is used, whether the figure is cut with the chisel, modelled in clay, or cut in metal or plaister.

There are three kinds of relievo:

Alto-relievo, or high relief, when the figures are so prominent from the ground, that merely a small part of them remains attached to it.

Mezzo-relievo, or half-relief, when one half of the figure rises from the ground, in such a manner that the figure appears divided by it.

Basso-relievo, or bas-relief (low relief), when the work is raised but little from the ground, as in medals, and generally in friezes and other ornamented parts of buildings.

Bas-relief is the comprehensive term by which all works in relievo are denominated indiscriminately. See SCULPTURE.

RELIEVO, or *Relief*, in painting, is the degree of boldness with which the figures seem, at a due distance, to stand out from the ground of the painting. See PAINTING.

RELIGION. Seditious words in derogation of the established religion are indictable, as tending to a breach of the peace. 1 Haw.7.

REMAINDER, in law, is an estate limited in lands, tenements, or rents, to be enjoyed after the expiration of another particular estate.

An estate in remainder is an estate limited to take effect and be enjoyed after another estate is determined. As if a man seised in fee simple grants lands to one for 20 years, and after the determination of the said term, then to another and his heirs for ever: here the former is tenant for years, remainder to the latter in fee. In the first place, an estate for years is created or carved out of the fee, and given to the former, and the residue and the remainder of it is given to the latter. Both their interests are in fact only one estate; the present term of years, and the remainder afterwards, when added together, being equal only to one estate in fee. 2 Black. c. 11.

The word remainder is no term of art, nor is it necessary to create a remainder. So that any words sufficient to shew the intent of the party, will create a remainder; because such estates take their denomination of remainder more from the natnre and manner of their existence after they are limited, than from any previous quality inherent in the word. See Fearne on Remainders.

There is this difference between a remainder and a reversion: in case of a reversion, the estate granted, after the limited time, reverts to the grantor or his heirs; but by a remainder it goes to some third person, or a stranger.

REMEMBRANCERS, antiently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first fruits. The king's remembrancer enters in his office all recognizances taken before the barons, for any of the king's debts, for appearances, or observing of orders; he also takes all bonds for the king's debts, &c. and makes out processes thereon. He likewise issues processes against the collectors of the customs, excise, and others, for their accounts; and informations upon penal statutes are entered and sued in his office, where all proceeding in matters upon English bills in the exchequer-chamber remain. His duty further is to make out the bills of compositions upon penal laws, to take the statement of debts; and into his office are delivered all kinds of indentures and other evidences, which concern the assuring of any lands to the crown. He every year, in crastino Animarum, reads in open court the statute for election of sheriffs; and likewise openly reads in court, the oaths of all the officers, when they are admitted.

The lord treasurer's remembrancer is charged to make out process against all sheriffs, escheators, receivers, and bailiffs, for their accounts. He also makes out writs of fieri facias, and extent for debts due to the king, either in the pipe or with the auditors; and process for all such revenue as is due to the king, on account of his tenures. He takes the account of sheriffs; and also keeps a record, by which it appears whether the sheriffs or other accountants pay their profers due at Easter and Michaelmas; and at the same time he makes a record, whereby the sheriffs or other accountants keep their prefixed days; there are likewise brought into this office all the accounts of customers, comptrollers, and accountants, in order to make entry thereof on record; also all estreats and amercements are certified here, &c.

The remembrancer of the first fruits takes all compositions and bonds for the payment of first fruits and tenths; and makes out process against such as do not pay the same.

REMIT, in commerce. To remit a sum of money, bill, or the like, is to send the sum of money, &c.

REMITTER, in law, is where one that has a right to lands, but is out of possession, has afterwards the freehold cast upon him by some subsequent defective title, and enters by virtue of that title; in this case the law remits him to his antient and more certain right, and by an equitable fiction supposes him to have gained possession in consequence and by virtue thereof; and this, because he cannot possibly obtain judgment at law, to be restored to his prior right, since he is himself the tenant of the land. 3 Black. 190.

REMORA, the *sucking-fish*. See ECHENEIS.

REMOVER, in law, is where a suit is removed or taken out of one court into another; and is the opposite of remanding a cause, or sending it back into the same court whence it was first called.

RENDER, in law, is used in levying a fine: which is either single, whereby nothing is granted or rendered back again by the cognizee to the cognizor; or double, which contains a grant or render back again of some real common, or other thing, out of the land itself to the cognizor.

RENDEZVOUS, or RENDEVOUS, a place appointed to meet in, at a certain day and hour.

RENEALMIA, in botany, a genus of the monogynia order, belonging to the monandria class of plants. The corolla is trifid; the nectarium oblong; the calyx monophyllous; the anthera sessile, opposite to the nectarium; the berry is fleshy. There is only one species, a native of Surinam.

RENT, is a certain profit issuing yearly, out of lands and tenement corporeal.

There are at common law three kinds of rents; rent service, rent charge, and rent seck, or rack rent.

Rent service is where the tenant holds his land of his lord by fealty and certain rent; or by homage, fealty, and certain rent; or by other service and certain rent; and it is called a rent service, because it has some corporal service incident to it, which at least is fealty. Rent charge is so called because the land for payment of it is charged with a distress. Rent seck, or rack rent, is where the land is granted without any clause of distress for the same. 1 Inst. 141.

The time for payment of rent, and consequently for a demand, is such a convenient time before the sun-setting of the last day, as will be sufficient to have the money counted; but if the tenant meets the lessor on the land at any time of the last day of payment, and tenders the rent, that is sufficient tender, because the money is to be paid indefinitely on that day, and therefore a tender on that day is sufficient. See DISTRESS.

RENTERING, in the manufactories, the same with fine-drawing. It consists in sewing two pieces of cloth edge to edge, without doubling them, so that the seam scarcely appears; and hence it is denominated fine-drawing. It is a French word meaning the same thing, and is derived from the Latin retrahere, or re, in, and trahere, because the seam is drawn in or covered. It is said, that in the East Indies, if a piece of fine muslin is torn, and afterwards mended by the fine-drawers, it will be impossible to discover where the rent was. In this country the dexterity of the fine-drawers is not so great as that of those in the East; but it is still such as to enable them to defraud the revenue, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole as of a piece, and by that means avoid the duties, penalties, &c. The trick was first discovered in France by M. Savary.

RenterING, in tapestry, is the working new warp into a piece of damaged tapestry, whether eaten by the rats or otherwise destroyed, and on this warp to restore the antient pattern or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers is included that of renterers.

RENVERSE', *inverted*. See HERALDRY.

REPARATIONE FACIENDA, a writ which lies in divers cases, one of which is, where three are tenants in common or joint tenants, as pro indiviso, of a mill or house which is fallen into decay, and the one being willing to repair it, the other two will not; in this case, the party willing shall have this writ against the other two. F. N. B. 127.

REPARATIONS. A tenant for life or years, may cut down timber trees to make reparations, although he is not compelled thereto; as where a house is ruinous at the time of the lease made, and the lessee suffers it to fall, he is not bound to rebuild it, and yet if he fells timber for reparations he may justify the same. Co. Litt. 54.

REPEAT, in music, a character shewing that what was last played or sung must be repeated or gone over again.

REPELLENTS, medicines supposed to have the power of sending back into the mass of the blood such morbid humours as had been secreted from it. The term is now left out of the materia medica.

REPERCUSSION, in mechanics. See REFLECTION.

REPERCUSSION, in music, a frequent repetition of the same sound.

REPERTORY, a place in which things are orderly disposed, so as to be easily found when wanted. The indexes of books are repertories, shewing where the matters sought for are treated of. Common-place books are also kinds of repertories.

REPETEND, in arithmetic, denotes that part of an infinite decimal fraction, which is continually repeated. Thus in the numbers 2.131313, the figures 13 are the repetend. These repetends chiefly arise in the reduction of vulgar fractions to decimals, as $\frac{1}{7}$ = 0.142857 142857 142857, and so on, for ever. A single repetend is that in which only one figure repeats, as $\frac{1}{3}$ =. 333 ; and a compound repetend is that in which two or more figures are repeated, as $\frac{13}{99}$ =. 131313, &c. To find the value of any repetend, or to reduce it to a vulgar fraction, "taken the given repeating figure or figures for a numerator; and for the denominator, take as many 9s as there are figures in the repetend: thus the fraction answering to 123123, &c. is $\frac{123}{999}=\frac{41}{333}$.

REPETITION, in music, denotes a reiterating or playing over again the same part of a composition, whether it is a whole strain, part of a strain, or double strain, &c. The repetition is denoted by a character called a repeat, which is varied so as to express the various circumstances of a repeat.

REPETITION, in rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

REPLEADER. Whenever a repleader is granted, the pleadings must begin de novo at that stage of them, whether it is the plea, replication, rejoinder, or whatever else, wherein there appears to have been the first default, or deviation from the regular course. When a repleader is awarded, it must be without costs. 3 Black. 395.

REPLETION. See MEDICINE.

REPLEVIN, is the writ called replegiare facias by him who has cattle or other goods distrained by another, for any cause, and putting in surety to the sheriff, that upon delivery of the thing distrained, he will prosecute the action against the distrainer. Co. Lit. 12.

In this writ or action, both the plaintiff and defendant are called actors; the one, that is, the plaintiff, suing for damages, and the avowant or defendant to have a return of the goods or cattle. 2 Bond, 84.

That the avowant is in the nature of a plaintiff, appears, 1st. from his being called an actor, which is a term in the civil law, and signifies plaintiff: 2dly, from his being entitled to have judgment de retorno habendo, and damages as plaintiffs; 3dly, from this, that the plaintiff might plead in abatement of the avowry, and consequently such avowry must be in the nature of an action. Carth. 112.

Replevins by writ, issue properly out of chancery, returnable into the courts of K. B. and C. B. at Westminster. In order to obtain a replevin, application must be made to the sheriff; or one of his deputies, and security given that the party replevying will pursue his action against the distrainer; for which purpose, by the antient law, he is required to put in pledges to prosecute; and that if the right is determined against him, he will return the distress again, for which purpose he is to find pledges to make return. These pledges are discretionary, and at the peril of the sheriff. 3 Black. 147.

After the goods are delivered back to the party replevying, he is then bound to bring his action of replevin against the distrainer, which may be prosecuted in the county court, be the distress of what value it may; but either party may remove it to the superior courts of king's-bench or common-pleas, the plaintiff at pleasure, and the defendant upon reasonable cause. 3 Black. 149.

If the sheriff is shewn a stranger's goods, and he takes them, an action of trespass lies against him, for otherwise he could have no remedy; for being a stranger he cannot have the writ de proprietate probanda; and was he not intitled to this remedy, it would be in the power of the sheriff to strip a man's house of all his goods. 2 Rol. Abr. 552.

If it is determined for the plaintiff, namely, that the distress was wrongfully taken, he has already got his goods back into his own possession, and shall keep them, and moreover recover damages. But if the defendant prevails by the default or nonsuit of the plaintiff, then he shall have a writ de retorno habendo, by which the goods or chattels which were distrained and then replevied, are returned again into his custody, to be sold, or otherwise disposed of, as if no replevin had been made. If the distress was for damage feasant, the distrainor may keep the goods so returned, until tender shall be made of sufficient amends. Rol. Abr. 146.

On a retorno habendo awarded, the party desiring to have the cattle or goods restored, must shew them to the sheriff, for otherwise the sheriff may not know them.

REPLICATION, in logic, the assuming or using the same term twice in the same proposition.

REPLICATION, an exception or answer of the plaintiff in a suit to the defendant's plea; and is also that which the complainant replies to the defendant's answer in chancery, &c. The replication is to contain certainty, and not to vary from the declaration, but must pursue and maintain the cause of the plaintiff's action; otherwise it will be a departure in pleading, and going to another matter. 1 Inst. 304.

REPORT, in law, is a public relation of cases judicially argued, debated, resolved, or adjudged, in any of the king's courts of justice, with the causes and reasons of the same, as delivered by the judges. Also when the court of chancery, or any other court, refers the stating of a case, or the comparing of an account, to a master in chancery, or other referee, his certificate thereon is called a report.

REPOSE, in painting, certain masses or large assemblages of light and shade, which being well conducted, prevent the confusion of objects and figures, by engaging and fixing the eye so that it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups gradually proceeding from stage to stage.

REPRESENTATION. There is an heir by representation, where the father dies, in the life of the grandfather, leaving a son, who shall inherit the grandfather's estate before the father's brother, &c.

REPRIEVE, to suspend a prisoner from the execution and proceeding of the law at that time. Every judge who has power to order any execution, has power to reprieve.

REPRISALS. See LETTERS OF MARQUE.

REPRISE, or REPRIZE, at sea, is a merchant-ship, which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party.

If a vessel thus retaken has been 24 hours in the possession of the enemy, it is deemed a lawful prize; but if it is retaken within that time, it is to be restored to the proprietor, with every thing in it, upon his allowing one-third to the vessel which made the reprise. Also if the reprise has been abandoned by the enemy, either in a tempest or from any other cause, before it has been led into any port, it is to be restored to the proprietor.

REPRODUCTION, is usually understood to mean the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be aised from slips and cuttings; and some late observations have shown, that there are some animals which have the same property. The polype (see POLYPUS) was the first inst nce we had of this; but we had scarcely time to wonder at the discovery Mr. Trembley had made, when Mr. Bonett discovered the same property in a species of water-worm. Amongst the plants which may be raised from cuttings, there are some which seem to posssess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again.

It deserves inquiry, whether this reproduction will or will not take place in whatever part the worm is cut? In order to try this, Mr. Bonett entered on a course of many experiments on the water-worms which have this property. These are, at their common growth, from two to three inches long, and of a brownish colour, with a cast of reddish. From one of these worms he cut off the head and tail, taking from each extremity only a small piece of a twelfth of an inch in length; but neither of these pieces was able to reproduce what was wanting. They both perished in about 24 hours; the tail first, and afterwards the head. As to the body of the worm from which these pieces were separated, it lived as well as before, and seemed indeed to suffer nothing by the loss, the head-part being immediately used as if the head was on, boring the creature's way into the mud. There are, besides this, two other points in which the reproduction will not take place; the one of these is about the fifth or sixth ring from the head, and the other at the same distance from the tail; and in all probability the condition of the great artery in these parts is the cause of this.

What is said of the want of the reproductive power of these parts, relates only to the head and tail ends; for, as to the body, it feels very little inconvenience from the loss of what is taken off, and very speedily reproduces those parts. Where then does the principle of life reside in such worms, which, after having their heads cut off, will have not only the same motions, but even the inclinations, that they had before? And yet this difficulty is very small, compared to several others. Is this wonderful reproduction of parts only a natural consequence of the laws of motion; or is there lodged in the body of the creature a chain of minute buds or shoots, a sort of little embryos, already formed, and placed in such parts where the reproductions are to begin? Are these worms only mere machines, or are they, like more perfect animals, a sort of compound, the springs of whose motions are actuated or regulated by a sort of soul? And if they have themselves such a principle, how is it that this principle is multiplied, and is found in every separate piece? Are we to believe with Malpighi, that these sorts of worms are all heart and brain from one end to the other? This may be; but yet if we knew that it was so, we should know in reality but very little the more for knowing it: and it seems, after all, that, in cases of this kind, we are only to admire the works of the great Creator, and sit down in silence.

The nice sense of feeling in spiders has been much talked of by naturalists; but it appears that these worms have yet somewhat more surprising in them in regard to this particular. If a piece of stick, or any other substance, is brought near them, they do not stay for its touching them, but begin to leap and frisk about as soon as it comes towards them. There want, however, some further experiments to ascertain whether this is really owing to feeling or sight; for though we can discover no distinct organs of sight in these creatures, yet they seem affected by the light of the sun or a candle, and always frisk about in the same manner at the approach of either; nay, even the moonlight has some effect upon them.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a tree, every piece of which will in the same manner produce other trees. The case is the same with these worms; they are cut to pieces, and these several pieces become perfect animals; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. It has been supposed by some that these worms were oviparous; but Mr. Bonett, on cutting one of them to pieces, having observed a slender substance, resembling a small filament, to move at the end of one of the pieces, separated it; and on examining it with glasses, found it to be a perfect worm, of the same form with its parent, which lived and grew larger in a vessel of water into which he put it. These small bodies are easily divided, and very readily complete themselves again, a day usually serving for the production of a head to the part that wants one; and, in general, the smaller and more slender the worms are, the sooner they complete themselves after this operation. When the bodies of the large worms are examined by the microscope, it is very easy to see the appearance of the young worms alive, and moving about within them; but it requires great precision and exactness to be certain of this; since the ramifications of the great artery have very much the appearance of young worms, and they are kept in a sort of continual motion by the systoles and diastoles of the several portions of the artery, which serve as so many hearts. It is very certain, that what we force in regard to these animals by our operations, is done also naturally every day in the brooks and ditches where they live. A curious observer will find in these places many of them without heads or tails, and some without either; as also other fragments of various kinds, all which are then in the act of completing themselves; but whether accidents have reduced them to this state, or they thus purposely throw off parts of their own body for the reproduction of more animals, it is not easy to determine. They are plainly liable to many accidents, by which they lose the several parts of their body, and must perish very early if they had not a power of reproducing what was lost; they often are broken into two pieces, by the resistance of some hard piece of mud which they enter; and they are subject to a disease, a kind of gangrene, rotting off the several parts of their bodies, and must inevitably perish by it, had they not this surprising property.

This worm was a second instance, after the polype, of the surprising power in an animal of recovering its most essential parts when lost. But nature does not seem to have limited her beneficence in this respect to these two creatures. Mr. Bonett tried the same experiments on another species of water-worm, differing from the former in being much thicker. This kind of worm, when divided in the summer season, very often shows the same property; for if it is cut into three or four pieces, the pieces will lie like dead for a long time, but afterwards will move about again; and will be found in this state of rest to have recovered a head, or a tail, or both. After recovering their parts, they move very little; and according to this gentleman's experiments, seldom live more than a month.

It should seem, that the more difficult success of this last kind of worm, after cutting, and the long time it takes to recover the lost parts, if it does recover them at all, are owing to its thickness; since we always find in that species of worms which succeeds best of all, that those which are thinnest recover their parts much sooner than the others.

The water-insects also are not the only creatures which have this power of recovering the lost parts. The earth affords us some already discovered to grow in this manner from their cuttings, and these not less deserving our admiration than those of the water: the common earth-worms are of this kind. Some of these worms have been divided into two, others into three or four, pieces; and some of these pieces, after having passed two or three months without any appearance of life or motion, have then begun to reproduce a head or tail, or both. The reproduction of the anus, after such a state of rest, is no long work; a few days do it; but it is otherwise with the head, that does not seem to perform its functions in the divided pieces till about seven months after the separation. It is to be observed, that in all these operations, both on earth and water-worms, the hinder part suffers greatly more than the fore part in the cutting; for it always twists itself about a long time, as if actuated by strong convulsions; whereas the head usually crawls away without the appearance of any great uneasiness.

The reproduction of several parts of lobsters, crabs, &c. makes also one of the great curiosities in natural history. That, in lieu of an organical part of an animal broken off, another shall rise perfectly like it, may seem inconsistent with the modern system of generation, where the animal is supposed to be wholly formed in the egg. Yet has the matter of fact been well attested by the fishermen, and even by several virtuosoes who have taken the point into examination, particularly M. de Reaumur and M. Perrault, whose skill and exactness in things of this nature will hardly be questioned. The legs of lobsters, &c. consist each of five articulations: now, when any legs happen to break by any accident, as in walking, &c. which frequently happens, the fracture is always found to be in a part near the fourth articulation; and what they thus lose is precisely reproduced some time afterwards; that is, a part of a leg shoots out, consisting of four articulations, the first of which has two claws as before, so that the loss is entirely repaired.

If a lobster's leg is broken off by design at the fourth or fifth articulation, what is thus broken off always comes again; but it is not so if the fracture is made in the first, second, or third articulation. In those cases, the reproduction is very rare if things continue as they are. But what is exceedingly surprising is, that they do not; for, upon visiting the lobster maimed in these barren and unhappy articulations, at the end of two or three days, all the other articulations are found broken off to the fourth; and it is suspected they have performed the operation on themselves, to make the reproduction of a leg certain.

The part reproduced is not only perfectly like that retrenched, but also, in a certain space of time, grows equal to it. Hence it is that we frequently see lobsters which have their two large legs unequal, and that in all proportions. This shows the smaller leg to be a new one.

A part thus reproduced being broken, there is a second reproduction. The summer, which is the only season of the year when the lobsters eat, is the most favourable time for the reproduction. It is then performed in four or five weeks; whereas it takes up eight or nine months in any other season. The small legs are sometimes reproduced, but more rarely, as well as more slowly, than the great ones; the horns do the same. The experiment is most easily tried on the common crab.

REPTILES, in natural history, an order of amphibia, the character of which is, that they breathe through the mouth; have feet, and flat naked ears, without auricles. There are five genera of reptiles, viz.

Testudo
Draco
Lacerta
Rana
Siren.

REPULSION, in physics, that property in bodies, by which, if they are placed just beyond the sphere of each other's attraction of cohesion, they mutually fly from each other.

That there is a force which opposes the approach of bodies towards each other, and which tends to separate them farther from each other, is obvious from the slightest view of the phenomena of nature. When we present the north pole of a magnet A to the same pole of another magnet B, suspended on a pivot, and at liberty to move, the magnet B recedes as the other approaches; and by following it with A at a proper distance, it may be made to turn round on its pivot with considerable velocity. In this case there is evidently some force which opposes the approach of the north poles of A and B, and which causes the moveable magnet to retire before the other. There is then a repulsion between the two magnets, a repulsion which increases with the power of the magnets; and this power has been made so great, by a proper combination of magnets, that all the force of a strong man is insufficient to make the two north poles touch each other. The same repulsion is equally obvious on electrical bodies; and indeed it is by means of it alone that the quantity of electricity is measured by philosophers. If two cork balls are suspended from a body with silk threads, so as to touch each other; if we charge the body with electricity, the cork balls separate from each other, and stand at a distance proportional to the quantity of electricity with which the body is charged; the balls of course repel each other. See ELECTRICITY.

But it is not in electric and magnetic bodies only that repulsion is perceived. Newton has shewn that it exists also between two pieces of glass. He found that when a convex lens is put upon a flat glass, it remains at the distance of the $\frac{1}{137}$th part of an inch, and a very considerable pressure is required to diminish this distance; nor does any force which can be applied bring them into actual mathematical contact; a force may indeed be applied sufficient to break the glasses in pieces; but it may be demonstrated that it does not diminish their distance much beyond the $\frac{1}{1000}$th part of an inch. There is, therefore, a force of repulsion which prevents the two glasses from touching each other.

That the particles of air repel each other is evident; for a considerable force is required to keep them as near each other as we find them at the surface of the earth; and when this force is removed, they separate from each other, that is to say, the air expands. Nor is it known how far this expansion extends. Air has been artificially expanded to 3000 times its usual bulk, and doubtless at great heights in the atmosphere its expansion is still much greater than that. On the other hand, air may be forcibly condensed, that is to say, its particles may be made to approach nearer each other; but a considerable force is required to produce this effect; and this force increases nearly as the density: if it is removed, the particles again separate, and the air assumes its former bulk. What are the limits of this condensation is not known; but air has been forcibly compressed to 1000th part of its natural bulk. Thus we see that the particles of air may be made to approach 16 times nearer each other. The elasticity of air, or the effort which it makes when compressed to resume its former bulk, is evidently the consequence of a repulsive force which its particles exert. All gaseous fluids possess the same repulsive force, and are indebted to it for their elasticity.

The particles of solid elastic bodies likewise repel each other; for they also, when forcibly compressed, resume their former size, and of course their particles repel each other. It has been demonstrated by philosophers, that all liquids are capable of a certain degree of compression, and that when the compressing force is removed they resume their former bulk; consequently the particles of these bodies also repel each other.

All bodies then possess a repulsive force, which exerts itself either at sensible distances or at insensible distances; of course the repulsions may be divided into two classes.

The only sensible repulsions with which we are acquainted, take place at small distances. They may be reduced to two kinds, namely, electricity and magnetism. It has been ascertained, that bodies possessed of the same kind of electricity repel each other; and likewise the same magnetic poles of bodies repel each other; while, on the other hand, differently electrified bodies, and the different poles of magnetic bodies, attract each other. Repulsion increases, as far as has been ascertained, inversely as the square of the distance; consequently, at the point of contact it is infinite.

Insensible repulsion is most conspicuous in elastic fluids, as air and the gases; but it is exhibited also by elastic bodies in general. In these, if a judgment can be formed from the experiments on air, the repulsion increases nearly at the rate of $\frac{1}{a^3}$.

Insensible repulsion may either be a force inherent in the particles of bodies, or it may belong exclusively to some particular body combined with these particles. The first of these hypotheses seems to have been adopted by Newton.

Other philosophers have supposed that repulsion is not a property inherent in all matter, but confined to a peculiar substance which has been generally considered as caloric. According to this hypothesis, there are two kinds of matter, one whose particles attract, another whose particles repel. Let us call the first cohesive matter, and the other caloric; and let us suppose also, what must be the case, that cohesive matter and caloric attract each other with a certain force, in certain circumstances. This will explain the expansive power of caloric, which combining with the particles of other cohesive matter, destroys the cohesion of those particles, and acts upon the body as a repulsive force; and this appears at least to explain the repulsion which exists in elastic, and, perhaps, other fluids.

Before we quit this subject, it will be worth while to shew, by an example, that the repulsion between the particles of caloric often acts as a real chemical force, and that it affords a key to explain several phenomena which at first sight appear nearly contradictory. Why do bodies require different temperatures in order to unite? and why does the presence of caloric in many cases favour, or rather produce, union, while it prevents or destroys it in others?

Some substances, phosphorus for instance, combine with oxygen at the common temperature of the atmosphere; others, as carbon, require a higher temperature; and others, as hydrogen and azotic gas, do not combine, except at a very high temperature. To what are these differences owing?

It is evident, that whatever diminishes the cohesion which exists between the particles of any body, must tend to facilitate their chemical union with the particles of other bodies. This is the reason that bodies combine more easily when held in solution by water, or when they have been previously reduced to a fine powder. Now caloric possesses the property of diminishing cohesion: and one reason why some bodies require a high temperature to cause them to combine is, that at a low temperature the attraction of cohesion is in them superior to that of affinity; accordingly, it becomes necessary to weaken that attraction by caloric till it becomes inferior to that of affinity. The quantity of caloric necessary for this purpose must vary according to the strength of the cohesion and of the affinity; it must be inversely as the affinity, and directly as the cohesion. Wherefore, if we knew precisely the force of the cohesion between the particles of any body, and of the affinity between the particles of that body and of any other, we could easily reduce the temperature necessary to calculation.

That caloric or temperature acts in this manner, cannot be doubted, if we consider that other methods of diminishing the attraction of cohesion may be substituted for it with success. A large lump of charcoal, for instance, will not unite with oxygen at so low a temperature as the same charcoal will do when reduced to a very fine powder; and charcoal will combine with oxygen at a still lower temperature, if it is reduced to its integrant particles, by precipitating it from alcohol, as Dr. Priestley did by passing the alcohol through red-hot copper. And to shew that there is nothing in the nature of oxygen and carbon which renders a high temperature necessary for their union, if they are presented to each other in different circumstances, they combine at the common temperature of the atmosphere; for if nitric acid, at the temperature of 6°, is poured upon charcoal-powder, well dried in a close crucible, the charcoal takes fire, owing to its combining with the oxygen of the acid. And in some other situations, carbon is so completely divided that it is capable of combining with the oxygen of the atmosphere, or, which is the same thing, of catching fire at the common temperature: this seems to be the case with it in those pyrophori that are formed by distilling to dryness several of the neutral salts which contain acetous acid. These observations are sufficient to shew, that caloric is in many cases necessary in order to diminish the attraction of cohesion.

But there is a difficulty still remaining. How comes it that certain bodies will combine with oxygen without the assistance of any foreign heat, provided the combination is once begun, though a quantity of caloric is necessary to begin the combination; and that other bodies require to be surrounded by a great quantity of caloric during the whole time of their combining with oxygen? Alcohol, for instance, if once kindled, burns till it is quite consumed; and this is the case with oils also, provided they are furnished with a wick.

We should err very much, were we to suppose that a high temperature is not as necessary to these substances during the whole of their combustion as at the commencement of it: for Mr. Monge found, on making the trial, that a candle would not burn after the temperature of the air around it was reduced below a certain point.

All substances which continue to burn after being once kindled are volatile, and they burn the easier in proportion to that volatility. The application of a certain quantity of caloric to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the very same phenomena; only as they are less volatile, it is necessary to assist the process by means of the capillary attraction of the wick, which confines the action of the caloric evolved to a small quantity of oil, and thus enables it to produce the proper effect. In short, then, every substance which is capable of continuing to burn after being once kindled is volatile, or capable of being converted into vapour by the degree of heat at first applied. The reason that a live coal will not burn when suspended insulated in the air, is not, as Dr. Hutton supposed, because its light is dissipated, but because the coal cannot be converted into vapour by the degree of heat which it contains, and because the cohesion of its particles is too great to allow it to combine with oxygen without some such change. There are some coals, however, which contain such a quantity of bitumen, that they will burn even in the situation supposed by Dr. Hutton, and continue to burn, provided they are furnished with any thing to act as a wick. It is needless to add, that bitumen, like oil, is easily converted into vapour.

But this explanation, instead of removing our difficulties, has only served to increase them: for if caloric only acts by diminishing the attraction of cohesion, and converting these substances into vapour, why do not all elastic fluids combine at once without any additional caloric? why do not oxygen and hydrogen, when mixed together in the state of gas, unite at once and form water? and why do not oxygen and azote, which are constantly in contact in the atmosphere, unite also and form nitrous gas? Surely it cannot be the attraction of cohesion that prevents this union. And if it is ascribed to their being already combined with caloric, how comes it that an additional dose of one of the ingredients of a compound decomposes it? Surely, as Mr. Monge has observed, this is contrary to all the other operations in chemistry.

That the particles of fluids are not destitute of an attraction for each other, is evident rom numberless facts. The particles of water draw one another after them in cases of capillary attraction; which is probably owing to the attraction of cohesion. It is owing to the attraction of cohesion, too, that small quantities of water form themselves into spheres; nor is this attraction so weak as not to be perceptible. If a small plate of glass is laid upon a globule of mercury, the globule, notwithstanding the pressure, continues to preserve its round figure. If the plate is gradually charged with weights one after another, the mercury becomes thinner and thinner, and extends itself in the form of a plate; but as soon as the weights are removed, it recovers its globular figure again, and pushes up the glass before it. Here we see the attraction of cohesion, not only superior to gravitation, but actually overcoming an external force. And if the workman, after charging his plate of glass with weights, when he is forming mirrors, happens to remove these weights, the mercury which had been forced from under the glass, and was going to separate, is drawn back to its place, and the glass again pushed up. Nor is the attraction of cohesion confined to solids and liquids; it cannot be doubted, that it exists also in gases; at least it is evident, that there subsists an attraction between gases of a different kind; for although oxygen and azotic gas are of different gravities, and ought therefore to occupy different parts of the atmosphere, we find them always mixed together; and this can only be ascribed to an attraction.

It seems evident, in the first place, that the affinity between the bases of the gases under consideration and oxygen, is greater than their affinity for that dose of caloric which produces their elastic form; for when they are combined with oxygen, the same dose will not separate them again. Let us take hydrogen for an instance. The affinity of hydrogen is greater for oxygen than for the caloric which gives it its gaseous form; but the oxygen is also combined with caloric, and there exists an attraction of cohesion between the particles of the hydrogen gas and oxygen gas; the same attraction subsists between those of oxygen gas and hydrogen gas. Now the sum of all these affinities (namely, the affinity between hydrogen and caloric, the affinity between oxygen and caloric, the cohesion of the particles of the hydrogen, and the cohesion of the particles of oxygen) is greater than the affinity between the hydrogen and oxygen; and therefore no decomposition can take place. Let the affinity between

Oxygen and caloric be	-	50
Hydrogen and caloric	-	50
Cohesion of oxygen for hydrogen		4
Cohesion of hydrogen	- -	2
Sum of quiescent affinities	-	106
The affinity of oxygen and hydrogen		105

The quiescent affinities being greater than the divellent affinities, no decomposition can take place.

Let now a quantity of caloric be added to the oxygen and hydrogen gas, it has the property of expanding them, and of course of diminishing their cohesion; while its affinity for them is so small, that it may be neglected. Let us suppose that it diminishes the cohesion of the oxygen 1, and of the hydrogen also 1, their cohesion will now be 3 and 1; and the quiescent affinities being only 104, while the divellent are 105, decomposition would of course take place, and a quantity of caloric would thus be set at liberty to produce the same effects upon the neighbouring particles.

Thus, then, caloric acts only by diminishing cohesion; and the reason that it is required so much in gaseous substances, and in those combinations into which oxygen enters, is the strong affinity of oxygen and the other bases of the gases for caloric; for owing to the repulsion which exists between the particles of that subtile substance, an effect is produced by adding large doses of it, contrary to what happens in other cases. The more of it is accumulated, the stronger is the repulsion between its particles, and therefore the more powerful is its tendency to fly off: and as this tendency is opposed by its affinity for the body and the cohesion of its particles, it must diminish both these attractions.

REPUTATION, or Fame. The security of reputation, or good name, from the arts of detraction and slander, is a right to which every man is intitled, by reason and natural justice; since, without this, it is impossible to have the perfect enjoyment of any other advantage or right. 1 Black. 134.

Reputation is properly under the protection of the law, as all persons have an interest in their good name, and scandal and defamation are injurious to it; though defamatory words are not actionable, otherwise than as they are a damage to the estate of the person injured. Wood's Inst. 37.

REQUESTS, *Court of*, an antient court of equity, instituted about the nineteenth year of Henry VII. See Court.

In the fortieth and forty-first years of queen Elizabeth, it was adjudged, upon solemn argument, in the court of common pleas, that the court of request was then no court of equity.

RESCRIPT, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question, or point of law, to serve as a decision thereof.

RESCUE, or Rescous, is the taking away and setting at liberty against law, any distress taken for rent, or services, or damage feasant; but the more general notion of rescous is, the forcibly freeing another from an arrest or some legal commitment; which being a high offence, subjects the offender not only to an action at the suit of the party injured, but likewise to fine and imprisonment at the suit of the king. Co. Lit. 160.

If goods are distrained without cause, or contrary to law, the owner may make rescue; but if they are once impounded, or even though taken without any cause, the owner may not break the pound and take them out, for then they are in custody of the law. 1 Black. 12. See Distress.

RESEARCH, in music, is a kind of prelude or voluntary played on the organ, &c. wherein the performer seems to search or look out for the strains and touches of harmony, which he is to use in the regular piece to be played afterwards.

RESEDA, *dyer's-weed, yellow-weed, weld*, or *wild-wood*, a genus of the order of trigynia, in the dodecandria class of plants; and in the natural method ranking under the 54th order, miscellaneæ. The calyx is monophyllous and partite; the petals laciniated; the capsule unilocular, and opening at the mouth. There are 13 species; of which the most remarkable is the luteola, or common dyer's weed, growing naturally in waste places in many parts of Britain. The young leaves are often undulated; the stalk is a yard high, or more, terminated with a long naked spike of yellowish-green flowers: the plant is cultivated and much used for dyeing silk and wool of a yellow colour. The great recommendation of the plant is, that it will grow with very little trouble, without dung, and on the very worst soils. For this reason it is commonly sown with, or immediately after, barley or oats, without any additional care except drawing a bush over it to harrow it in. The reaping of the corn does it little or no hurt, as it grows but little the first year; and the next summer it is pulled and dried like flax. Much care and nicety, however, is requisite, so as not to injure either the seed or stalk; or, which sometimes happens, damaging both, by letting it stand too long, or pulling it too green. To avoid these inconveniences, a better method of culture has been devised. This new method is, to plough and harrow the ground very fine, without dung, as equally as possible; and then sowing about a gallon of seed, which is very small, upon an acre, some time in the month of August. In about two months it will be high enough to hoe, which must be carefully done, and the plants left about six inches asunder. In March it is to be hoed again, and this labour is to be repeated a third time in May. About the close of June, when the flower is in full vigour, and the stalk is become of a greenish yellow, it should be pulled; a sufficient quantity of stems being left growing for seed till September.

RESERVE, *body of*, or *corps de reserve*, in military affairs, the third or last line of an army, drawn up for battle; so called because they are reserved to sustain the rest, as occasion requires; and not to engage, but in case of necessity.

RESIDENCE, is the continuance of a parson or vicar on his benefice. By statute 43d Geo. III. chap. 84, it is enacted that the statute 13th Eliz. c. 20, and its continuing statutes, are repealed; and that the penalties for non-residence under the act 21st Hen. VIII. are repealed; and that every spiritual person possessed of any archdeaconry, or other dignity, benefice, curacy, or chapelry, who shall, without exemption, or sufficient cause, as is specified in the acts of the 21st, 25th, and 28th Hen. VIII., absent himself from his benefice for more than three months in the year (unless he resides at some place where he has other dignity or benefice), and less than six, shall pay one-third of the annual value (deducting all out-goings, except curate's pay); when eight months, two-thirds; and when the whole year, three-fourths. The penalty, with costs, to go to the informer; but the penalty for non-residence cannot be recovered, if the parson has resided a whole year without absence before the action is brought.

Besides the exemptions contained in the above-mentioned act, the following persons are exempt: clerk, or deputy clerk, of the king's closet; chaplain of the house of commons; chaplain-general of the forces; brigade-chaplain on foreign service; chaplains of ships of the dock-yards, of garrisons, or of the corps of artillery, during the time of attending such offices; chaplain to any British factory, or in the household of any British minister, abroad; chancellor, or vicar-general, or in his absence, the surrogate, or official, in an ecclesiastical court; minor canon, vicar, choral, or other officer, in any cathedral or collegiate church; deans, subdeans, priests, or readers, in the king's private chapels; chaplain of the military asylum, of the hospitals of Chelsea, Greenwich, Haslar, and Plymouth, while attending their duty; preacher or reader at the inns of court or the rolls; the bursar, dean, vice-president, public tutor, or chaplain, or such other public officers, in the universities, or at Eton, or Winchester, or schoolmaster or usher in the same, or at Westminster; and persons entitled by the last of the above-mentioned statutes to the privilege of non-residence, till after forty years of age, shall not be entitled to it after thirty. The bishops may, if they think fit, grant licences for non-residence in certain cases, the fee for which shall not be more than ten shillings, independant of stamp-duty; and if the bishop refuses to grant the licence, the party who thinks himself aggrieved may appeal to the archbishop, on giving security for paying the expences of the appeal: the reasons for granting the licences shall be transmitted to the archbishop, for his examination and allowance; and during the vacancy of any see, the vicar-general may grant them, and they shall not be void on the death or removal of the granter, unless revoked by his successor.

A person, although he may reside on the living, is yet liable to the penalties of non-residence, if he resides in any other house than that appointed for his residence, except by such licence from the diocesan as has been stated, or while the tenant to whom the house of residence has been let continues in possession.

RESIDUAL FIGURE, in geometry, the figure remaining after subtracting a lesser from a greater.

Residual Root, in algebra, a root composed of two parts or members, connected together by the sign —.

Thus $x-y$ is a residual root, so called because its value is no more than the difference between its parts x and y.

RESIGNATION, in the canon law, the surrendering a benefice into the hands of the collator, or bishop.

RESIGNEE, in law, the person to whom a thing is resigned.

RESIN, in natural history, a viscid juice oozing either spontaneously, or by incision, from several trees, as the pine, fir, &c.

Resins. It is at present the opinion of chemists, that resins stand in the same relation to the volatile oils that wax does to the fixed. Wax is considered as a fixed oil saturated with oxygen; resins as volatile oils saturated with the same principle.

The resins are very numerous; and on account of the various purposes to which they are applied, and the peculiarity of their properties, constitute one of the most important genera of vegetable substances. Till lately they have been very much overlooked by chemists, who satisfied themselves with gleaning doubtful information from artists and manufacturers. Many erroneous opinions concerning them have of course been admitted into every system of chemistry. The subject has lately engaged the attention of Mr. Hatchett, whose consummate skill and happy talent for observation peculiarly fitted him for the task.

Resins often exude spontaneously from trees; they often flow from artificial wounds; and not uncommonly are combined at first with volatile oil, from which they are separated by distillation. The reader can be at no loss to form a notion of what is meant by resin, when he is informed that common rosin furnishes a very perfect example of a resin, and that it is from this substance that the whole genus derived their name: for rosin is very frequently denominated resin.

Resins may be distinguished by the following properties:

They are solid substances, naturally brittle; have a certain degree of transparency, and a colour most commonly inclining to yellow. Their taste is more or less acrid, and hot like that of volatile oils; but they have no smell unless they happen to contain some foreign body. They are all heavier than water. Their specific gravity varies from 1.0180 to 1.2289. They are all non-conductors of electricity; and when excited by friction, their electricity is negative.

When exposed to heat, they melt; and if the heat is increased, they take fire; and burn with a strong yellow flame, emitting at the same time a vast quantity of smoke.

They are all insoluble in water, whether cold or hot; but when they are melted along with water, or mixed with volatile oil and then distilled with water, they seem to unite with a portion of that liquid; for they become opaque, and lose much of their brittleness. This at least is the case with common rosin. They are all, with a few exceptions, soluble in alcohol, especially when assisted by heat. The solution is usually transparent; and when the alcohol is evaporated, the resin is obtained unaltered in its properties. When the solution is mixed with water, it becomes milky, and the resin falls in the state of a white powder. They are soluble also in sulphuric ether. Many of them are soluble in several of the fixed oils, especially in the drying oils. The greater number are soluble in the volatile oils; at least in oil of turpentine, the one commonly employed.

Hitherto it has been affirmed by all chemists, both antient and modern, that the alkalies do not exert action on the resins. Fourcroy, for instance, in his last work, affirms this in the most positive manner; but the experiments of Mr. Hatchett have demonstrated this opinion to be completely erroneous. He reduced a quantity of common rosin to powder, and gradually added it to a boiling lixivium of carbonat of potass; a perfect solution was obtained of a clear yellow colour, which continued permanent after long exposure to the air. The experiment succeeded equally with carbonat of soda, and with solutions of pure potass or soda. Every other resin tried was dissolved as well as rosin. Mr Hatchett's discovery must lead to very important consequences. The well-known fact, that the soap-makers in this country constantly mix rosin with their soap; that it owes its yellow colour, its odour, and its easy solubility in water, to this addition; ought to have led chemists to have suspected the solubility of resins in alkalies. No such consequence, however, was drawn from this notorious fact.

It has been supposed also that the acids are incapable of acting upon the resins. Fourcroy is equally positive with regard to this; and Gren speaks of it in such a manner, that every reader must conclude that he had tried the effect of nitric acid upon resins. Yet Mr. Hatchett has ascertained this opinion likewise to be erroneous, at least as far as nitric acid is concerned. He found that resins are thrown down from their solutions in alkalies in the state of a curdy precipitate; but when nitric acid is added in excess, the whole of the precipitate is redissolved in a boiling heat. This remarkable fact, which did not hold when sulphuric or muriatic acids were used, led him to try whether the resins were soluble in nitric acid. He poured nitric acid, of the specific gravity 1.38, on powdered rosin in a tubulated retort; and by repeated distillation formed a complete solution of a brownish yellow colour. The solution took place much sooner in an open matrass than in close vessels. The solution continues permanent, though left exposed to the air. It becomes turbid when water is added; but when the mixture is boiled, the whole is redissolved. When Mr. Hatchett collected the precipitate thrown down by water by filtration, he found that it still possessed the properties of resin. The resin is thrown down from nitric acid by potass, soda, and ammonia; but an excess of these alkalies redissolves the precipitate, and forms brownish orange-coloured liquids. When Mr. Hatchett dissolved resin in boiling nitric acid, the solution was attended with a copious discharge of nitrous gas; and when the powdered resin was thrown into cold nitric acid, a considerable effervescence soon took place, and a porous mass was formed, commonly of a deep orange-colour.

When resins are subjected to destructive distillation, we obtain, according to Gren, carbureted hydrogen and carbonic acid gas, a very small portion of acidulous water, and much empyreumatic oil. The charcoal is light and brilliant, and contains no alkali.

When volatile oils are exposed for some time to the action of the atmosphere, they acquire consistency, and assume the properties of resins. During this change they absorb a quantity of oxygen from the air. Westrum put 30 grains of oil of turpentine into 40 cubic inches of oxymuriatic acid gas. Heat was evolved; the oil gradually evaporated, and assumed the form of yellow resin. Mr. Proust observed, that when volatile oil is exposed to the air, it is partly converted into a resin, and partly into a crystallized acid; usually the benzoic or the camphoric. Hence we see that the oil is converted into two distinct substances. During this change oxygen is absorbed; and Fourcroy has observed that a portion of water is also formed. It is probable, from these facts, that resin is volatile oil deprived of a portion of its hydrogen, and combined with oxygen.

Hermstadt affirms, that to know whether any vegetable substance contains resin, we have only to pour some sulphuric ether upon it in powder, and expose the infusion to the light. If any resin is present, the ether will assume a brown colour.

Having now described the general properties of resinous bodies, it will be proper to take a more particular view of those of them which are of the most importance, that we may ascertain how far each possesses the general characters of resins, and by what peculiarities it is distinguished from the rest. The most distinguished of the resins are the following:

1. *Rosin.* This substance is obtained from different species of fir; as the pinus abies, sylvestris, larix, balsamea. It is well known that a resinous juice exudes from the pinus sylvestris, or common Scotch fir, which hardens into tears. The same exudation appears in the pinus abies, or spruce fir. These tears constitute the substance called thus, or common frankincense. When a portion of bark is stripped off these trees, a liquid juice flows out, which gradually hardens. This juice has obtained different names according to the plant from which it comes. The pinus sylvestris yields common turpentine; the larix, Venice turpentine; the balsamea, balsam of Canada, &c. All these juices, which are commonly distinguished by the name of turpentine, are composed of two ingredients; namely, oil of turpentine, and rosin. When the turpentine is distilled, the oil comes over, and the rosin remains behind. When the distillation is continued to dryness, the residuum is known by the name of common rosin, or colophonium; but when water is mixed with it while yet fluid, and incorporated by violent agitation, the mass is called yellow rosin. During winter the wounds made in the fir-trees become incrusted with a white brittle substance called barras or galipot, consisting of rosin united to a small portion of oil. The yellow rosin made by melting and agitating this substance in water, is preferred for most purposes; because it is more ductile, owing probably to its still containing some oil. The properties of rosin are those which have been detailed in the former part of this article. Its uses are numerous and well known.

2. *Mastich.* This resin is obtained from the pistacea lentiscus; a tree which grows in the Levant, particularly in the island of Chios. When transverse incisions are made into this tree, a fluid exudes, which soon concretes into yellowish semitransparent brittle grains. In this state it is sold under the name of mastich. It softens when kept in the mouth, but imparts very little taste. This has induced surgeons to employ it to fill up the cavities of carious teeth, which it does tolerably well. When heated, it melts, and exhales a fragrant odour. It contains a little volatile oil. It dissolves readily in fixed oils and in alcohol; but is too fusible and opaque to answer as a varnish. Mr. Hatchett found it soluble in alkalies and nitric acid with the phenomena described in the former part of this article. Its specific gravity is 1.074.

3. *Sandarach.* This resin is obtained from the juniperus communis, or common juniper. It exudes spontaneously, and is usually in the state of small round tears of a brown colour, and semitransparent, not unlike mastich, but rather more transparent and brittle. Besides the resinous part, it contains a peculiar principle. Mr. Hatchett found the resin of juniper soluble in alkalies and nitric acid. Its specific gravity is 1.092.

4. *Elemi.* This resin is obtained from the amyris elemifera; a tree which grows in Canada and Spanish America. Incisions are made in the bark during dry weather, and the resinous juice which exudes is left to harden in the sun. It comes to this country in long roundish cakes wrapped in flag-leaves. It is of a pale yellow colour, semitransparent; at first softish, but it hardens by keeping. Its smell is at first strong and fragrant, but it gradually diminishes. When distilled, it yields a portion of volatile oil. The residuum is a pure resin. Its specific gravity is 1.018.

5. *Tacamahac.* This resin is obtained from the fagara octandra, and likewise it is supposed from the populus balsamifera. It comes from America in large oblong masses wrapt in flag-leaves. It is of a light-brown colour, very brittle, and easily melted when heated. Mr. Hatchett found it soluble in alkalies and nitric acid with the usual phenomena. Its specific gravity is 1.046.

6. *Animé.* This resin is obtained from the hymenæa courbaril or locust tree, which is a native of North America. Animé resembles copal very much in its appearance; but is readily soluble in alcohol, which copal is not: this readily distinguishes them. It is said to be very frequently employed in the making of varnishes. Its specific gravity, according to Brisson, is 1.028.

7. *Ladanum,* or *labdanum.* This resin is obtained from the cystus creticus, a shrub which grows in Syria and the Grecian islands. See LABDANUM.

8. *Opobalsamum,* or *balm of Gilead.* This resin is obtained from the amyris Gi-

leadensis, a tree which grows in Arabia, especially near Mecca. It is so much valued by the Turks that it is seldom or never imported into Europe. We are of course ignorant of its composition. It is said to be at first turbid and white; and of a strong aromatic smell, and bitter, acrid, astringent taste; but by keeping, it becomes limpid and thin, and its colour changes first to green, then to yellow, and at last it assumes the colour of honey.

9. *Copaiva*, or *balsam of copaiva*. This resin is obtained from the copaifera officinalis; a tree which grows in South America, and some of the West Indian islands. The resinous juice exudes from incisions made in the trunk of the tree. The juice thus obtained is transparent, of a yellowish colour, an agreeable smell, a pungent taste, at first of the consistence of oil, but it gradually becomes as thick as honey. It is a combination of volatile oil and resin; the oil is easily obtained by distillation with water. It is employed in medicine.

10. *Dragon's blood*. This resin is obtained from different plants, as the calamus rotang, dracæna draco, and pterocarpus draco. It comes both from the East Indies and Spanish America; and it cannot be doubted that different vegetable substances have been confounded under the same name, the red colour having been formerly considered as sufficient to constitute dragon's blood. The substance of that name described by French writers has an astringent taste, and is partly soluble in water. This seems to be the dragon's blood of America, in which Proust detected abundance of tan. The dragon's blood which comes to this country from the East Indies is tasteless, and insoluble in water; but it dissolves in alcohol, which it tinges of a fine crimson. It dissolves also in fixed oils, tinging them red. It is in small masses wrapt in leaves. Colour dark red. Powder crimson. Brittle. Fracture glassy. Opaque. Melts when heated, and readily burns. These properties prove it to be a resin. We must, then, distinguish two distinct substances hitherto confounded under the same name. According to Brisson, the specific gravity of dragon's blood (probably the species which contains tan) is 1.204.

11. *Guaiac*. This resin is obtained from the guaiacum officinale, a treee which is a native of the West Indies. The resin exudes spontaneously, and is driven out melted by heating one end of the wood in billets previously bored longitudinally; the melted resin runs out at the extremity farthest from the fire. Guaiac is of a green colour, has some transparency, and is brittle. Its fracture is vitreous. When heated, it melts. It has no smell, and scarcely any taste. Alcohol dissolves it; but water has no effect upon it. When thrown on burning coals, it diffuses a fragrant odour. When swallowed in powder, it causes a burning sensation in the throat.

12. *Botany Bay resin*. This resin is said to be the produce of the acarois resinifera; a tree which grows abundantly in New Holland, especially near Botany Bay. Specimens of it were brought to London about the year 1799, where it was tried as a medicine. Some account was given of it in governor Philips's Voyage, and in White's Journal of a Voyage to New South Wales; but it is to professor Lichtenstein that we are indebted for an account of its chemical properties. The resin exudes spontaneously from the trunk of the singular tree which yields it, especially if the bark is wounded. It is at first fluid, but becomes gradually solid when dried in the sun. According to governor Philips, it is collected usually in the soil which surrounds the tree, having doubtless run down spontaneously to the ground. It consists of pieces of various sizes, of a yellow colour unless when covered with a greenish-grey crust. It is firm, yet brittle; and when pounded, does not stick to the mortar nor cake. In the mouth it is easily reduced to powder without sticking to the teeth. It communicates merely a slight sweetish astringent taste. When moderately heated, it melts; on hot coals it burns to a coal, emitting a white smoke which has a fragrant odour something like storax. When thrown into the fire, it increases the flame like pitch. It communicates to water the flavour of storax, but is insoluble in that liquid. When digested in alcohol, two-thirds dissolve: the remaining third consists of one part of extractive matter, soluble in water, and having an astringent taste; and two parts of woody fibre and other impurities, perfectly tasteless and insoluble. The solution has a brown colour, and exhibits the appearance and the smell of a solution of benzoin. Water throws it down unaltered. When distilled, the products were water, an empyreumatic oil, and charcoal; but it gives no traces of any acid, alkali, or salt, even when distilled with water.

Twelve parts were boiled in a solution of pure soda in water. Two parts of the resin were dissolved; the remaining ten parts were floating on the solution, cohering together in clots. No crystals were obtained by evaporating part of the solution; and when sulphuric acid was dropt into another portion, resin separated unaltered. When mixed with twice its weight of nitric acid, the resin swims unaltered on the surface; but when heat is applied, a considerable effervescence takes place. The digestion was continued till the effervescence stopped, and the resin swam on the surface of the liquid, collected together in clots. It was then separated by filtration. It had lost $\frac{1}{12}$th of its weight. The resin thus treated had acquired a bitterish taste, was not so easily melted as before, and alcohol was capable of dissolving only one-half of it. The solution was brown, tasted like bitter almonds; and when mixed with water, let fall a yellow resinous precipitate of a very bitter taste. The insoluble portion mixed with water, but formed a turbid liquid, which passed through the filtre. The nitric acid solution separated from the resin by filtration, was transparent; its colour was yellow; its taste bitter; and it tinged substances dipped into it of a yellow colour. By evaporation it yielded oxalic acid, and deposited a yellow earthy-like powder. This last substance was insoluble in water, and scarcely soluble in alcohol. Its taste was exquisitely bitter, like quassia. It mixed with the saliva, and readily stained the skin and paper yellow. The residuum continued bitter and yellow, but yielded no precipitate with potass and nitrat of lime. The bitter substance, into which this resin was thus converted by nitric acid, deserves particular attention. He suspects that it is capable of producing the same changes on all the resins: but this conjecture has been verified only with regard to colophonium, which he found to yield equally a yellow bitter substance.

13. The *green resin* which constitutes the colouring matter of the leaves of trees, and almost all vegetables, is insoluble in water, and soluble in alcohol. From the experiments of Proust we learn, that when treated with oxymuriatic acid it assumes the colour of a withered leaf, and acquires the resinous properties in greater perfection.

14. *Copal*. This substance, which deserves particular attention from its importance as a varnish, and which at first sight seems to belong to a distinct class from the resin, is obtained from the rhus copallinum, a tree which is a native of North America; but the best sort of copal is said to come from Spanish America. Copal is a beautiful transparent resinous-like substance, with a slight tinge of brown. When heated it melts like other resins; but it differs from them in not being soluble in alcohol, nor in oil of turpentine without peculiar management. Neither does it dissolve in the fixed oils with the same ease as the other resins. It resembles gum animé exactly in appearance; but is easily distinguished by the solubility of this last in alcohol. The specific gravity of copal varies.

RESISTANCE, or *resisting-force*, in philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect.

There are various kinds of resistance arising from the various natures and properties of the resisting bodies, and governed by various laws; as, the resistance of solids, the resistance of fluids, the resistance of the air, &c.

Resistance *of solids*, in mechanics, is the force with which the quiescent parts of solid bodies oppose the motion of others contiguous to them.

Of these there are two kinds: The first where the resisting and the resisted parts, *i.e.* the moving and quiescent bodies, are only contiguous, and do not cohere; constituting separate bodies or masses. This resistance is what Leibnitz calls resistance of the surface, but which is more properly called friction; for the laws of which, see the article Friction.

The second case of resistance, is where the resisting and resisted parts are not only contiguous, but cohere, being parts of the same continued body or mass. This resistance was first considered by Galileo, and may properly be called renitency.

Theory of the resistance of the fibres of solid bodies. To conceive an idea of this resistance, or renitency of the parts, suppose a cylindrical body suspended vertically by one end. Here all its parts, being heavy, tend downwards, and endeavour to separate the two contiguous planes or surfaces where the body is the weakest; but all the parts of them resist this separation by the force with which they cohere, or are bound together. Here then are two opposite powers, viz. the weight of the cylinder, which tends to break it; and the force of cohesion of the parts, which resists the fracture.

If now the base of the cylinder is increased without increasing its length, it is evident that both the resistance and the weight will be increased in the same ratio as the base; and hence it appears that all cylinders of the same matter and length, whatever their bases are, have an equal resistance, when vertically suspended.

But if the length of the cylinder is increased without increasing its base, its weight is increased, while the resistance or strength continues unaltered; consequently the lengthening has the effect of weakening it, or increases its tendency to break.

Hence, to find the greatest length a cylinder of any matter may have, when it just breaks with the addition of another given weight, we need only take any cylinder of the same matter, and fasten to it the least weight that is just sufficient to break it; and then consider how much it must be lengthened, so that the weight of the part added, together with the given weight, may be just equal to that weight, and the thing is done. Thus, let l denote the first length of the cylinder, c its weight, g the given weight the lengthened cylinder is to bear, and w the least weight that breaks the cylinder l, also x the length sought; then as $l : x :: c : \frac{cx}{l} =$ the weight of the longest cylinder sought; and this, together with the given weight g, must be equal to c, together with the weight w; hence then $\frac{cx}{l} + g = c + w$; therefore $x = \frac{c + w - g}{c}$ $l =$ the whole length of the cylinder sought. If the cylinder must just break with its own weight, then is $g = 0$, and in that case $x = \frac{c + w}{c} l$ is the whole length that just breaks by its own weight. By this means Galileo found that a copper wire, and of consequence any other cylinder of copper, might be extended to 4801 fathoms of 6 feet each.

If the cylinder is fixed by one end into a wall, with the axis horizontally; the force to break it, and its resistance to fracture, will here be both different; as both the weight to cause the fracture, and the resistance of the fibres to oppose it, are combined with the effects of the lever; for the weight to cause the fracture, whether of the weight of the beam alone, or combined with an additional weight hung to it, is to be supposed collected into the centre of gravity, where it is considered as acting by a lever equal to the distance of that centre beyond the face of the wall where the cylinder or other prism is fixed; and then the product of the said whole weight and distance, will be the momentum or force to break the prism. Again, the resistance of the fibres may be supposed collected into the centre of the transverse section, and all acting there at the end of a lever equal to the vertical semidiameter of the section, the lowest point of that diameter being immoveable, and about which the whole diameter turns when the prism breaks; and hence the product of the adhesive force of the fibres, multiplied by the said semidiameter, will be the momentum of resistance, and must be equal to the former momentum when the prism just breaks.

Hence, to find the length a prism will bear, fixed so horizontally, before it breaks, either by its own weight, or by the addition of any adventitious weight; take any length of such a prism, and load it with weights till it just breaks. Then, put

$l =$ the length of this prism,
$c =$ its weight,
$w =$ the weight that breaks it,
$a =$ distance of weight w
$g =$ any given weight to be borne,
$d =$ its distance,
$x =$ the length required to break.

Then $l : x :: c : \frac{cx}{l}$ the weight of the prism x, and $\frac{cx}{l} \times \frac{1}{2} x = \frac{cx^2}{2l} =$ its momentum; also $dg =$ the momentum of the weight g; therefore $\frac{cx^2}{2l} + dg$ is the momentum of the prism x and its added weight. In like manner $\frac{1}{2}cl + aw$ is that of the former or short prism, and the weight that broke it; consequently $\frac{cx^2}{2l} + dg = \frac{1}{2}cl + aw$, and $x = \sqrt{\frac{aw + \frac{1}{2}cl - dg}{c}} \times 2l$ is the length sought, that just breaks with the weight g at the distance d. If this weight g is nothing, then $x = \sqrt{\frac{aw + \frac{1}{2}cl}{c}} \times 2l$ is the length of the prism that just breaks with its own weight.

If two prisms of the same matter, having their bases and lengths in the same proportion, are suspended horizontally; it is evident that the greater has more weight than the lesser, both on account of its length, and of its base; but it has less resistance on account of its length, considered as a longer arm of a lever, and has only more resistance on account of its base; therefore it exceeds the lesser in its momentum more than it does in its resistance, and consequently it must break more easily.

Hence appears the reason why, in making small machines and models, people are apt to be mistaken as to the resistance and strength of certain horizontal pieces, when they come to execute their designs in large, by observing the same proportions as in the small.

When the prism, fixed vertically, is just about to break, there is an equilibrium between its positive and relative weight; and consequently those two opposite powers are to each other reciprocally as the arms of the lever to which they are applied, that is, as half the diameter to half the axis of the prism. On the other hand, the resistance of a body is always equal to the greatest weight which it will just sustain in a vertical position, that is, to its absolute weight. Therefore, substituting the absolute weight for the resistance, it appears, that the absolute weight of a body, suspended horizontally, is to its relative weight, as the distance of its centre of gravity from the fixed point or axis of motion, is to the distance of the centre of gravity of its base from the same.

The discovery of this important truth, at least of an equivalent to it, and to which this is reducible, we owe to Galileo. On this system of resistance of that author, Mariotte made an ingenious remark, which gave birth to a new system. Galileo supposes that where the body breaks, all the fibres break at once; so that the body always resists with its whole absolute force, or the whole force that all its fibres have in the place where it breaks. But Mariotte, finding that all bodies, even glass itself, bend before they break, shews that fibres are to be considered as so many little bent springs, which never exert their whole force till stretched to a certain point, and never break till entirely unbent. Hence those nearest the fulcrum of the lever, or lowest point of the fracture, are stretched less than those farther off, and consequently employ a less part of their force, and break later.

This consideration only takes place in the horizontal situation of the body; in the vertical, the fibres of the base all break at once; so that the absolute weight of the body must exceed the united resistance of all its fibres; a greater weight is therefore required here than in the horizontal situation; that is, a greater weight is required to overcome their united resistance, than to overcome their several resistances one after another. See TIMBER, *strength of*.

RESISTANCE *of fluids*, is the force with which bodies, moving in fluid mediums, are impeded and retarded in their motion.

A body moving in a fluid is resisted from two causes. The first of these is the cohesion of the parts of the fluid. For a body, in its motion, separating the parts of a fluid, must overcome the force with which those parts cohere. The second is the inertia or inactivity of matter, by which a certain force is required to move the particles from their places in order to let the body pass.

The retardation from the first cause is always the same in the same space, whatever the velocity may be, the body remaining the same; that is, the resistance is as the space run through in the same time; but the velocity is also in the same ratio of the space run over in the same time; and therefore the resistance from this cause, is as the velocity itself.

The resistance from the second cause, when a body moves through the same fluid with different velocities, is as the square of the velocity. For, first, the resistance increases according to the number of particles or quantity of the fluid struck in the same time; which number must be as the space run through in that time, that is, as the velocity: but the resistance also increases in proportion to the force with which the body strikes against every part; which force is also as the velocity of the body, so as to be double with a double velocity, and triple with a triple one, &c.; therefore, on both these accounts, the resistance is as the velocity multiplied by the velocity, or as the square of the velocity. Upon the whole therefore, on account of both causes, viz. the tenacity and inertia of the fluid, the body is resisted partly as the velocity and partly as the square of the velocity.

But when the same body moves through different fluids with the same velocity, the resistance from the second cause follows the proportion of the matter to be removed in the same time, which is as the density of the fluid.

Hence therefore, if d denotes the density of the fluid,
v the velocity of the body,
and a and b constant coefficients:

then $adv^2 + bv$ will be proportional to the whole resistance to the same body, moving with different velocities, in the same direction, through fluids of different densities, but of the same tenacity.

But to take in the consideration of different tenacities of fluids; if t denotes the tenacity, or the cohesion of the parts of the fluid, then $adv^2 + btv$ will be as the said whole resistance.

Indeed the quantity of resistance from the cohesion of the parts of fluids, except in glutinous ones, is very small in respect of the other resistance; and it also increases in a much lower degree, being only as the velocity, while the other increases as the square of the velocity, and rather more. Hence then the term btv is very small in respect of the other term adv^2; and consequently the resistance is nearly as this latter term, or nearly as the square of the velocity. This rule has been employed by most authors, and is very near the truth in slow motions; but in very rapid ones, it differs considerably from the truth, as we shall perceive below; not indeed from the omission of the small term ctv, due to the cohesion, but from the want of the full counterpressure on the hinder part of the body; a vacuum, either perfect or partial, being left behind the body in its motion; and also perhaps to some compression or accumulation of the fluid against the fore part of the body.

Resistance and retardation are used indifferently for each other, as being both in the same proportion, and the same resistance always generating the same retardation. But with regard to different bodies, the same resistance frequently generates different retardations; the resistance being as the quantity of motion, and the retardation as that of the celerity.

The retardations from this resistance may be compared together, by comparing the resistance with the gravity or quantity of matter. It is demonstrated that the resistance of a cylinder, which moves in the direction of its axis, is equal to the weight of a column of the fluid, whose base is equal to that of the cylinder, and its altitude equal to the height through which a body must fall in vacuo, by the force of gravity, to acquire the velocity of the moving body. So that, if a denotes the area of the face or end of the cylinder, or other prism, v its velocity, and n the specific gravity of the fluid; then, the altitude due to the velocity v being $\frac{v^2}{4g}$, the whole resistance, or motive force m, will be $n \times d \times \frac{v^2}{4g} = \frac{anv^2}{4g}$; the quantity g being $= 16\frac{1}{12}$ feet, or the space a body falls, in vacuo, in the first second of time. And the resistance to a globe of the same diameter would be the half of this. Let a ball, for instance, of 3 inches diameter, be moved in water with a celerity of 16 feet per second of time: now from experiments on pendulums, and on falling bodies, it has been found, that this is the celerity which a body acquires in falling from the height of 4 feet; therefore the weight of a cylinder of water of 3 inches diameter, and 4 feet high, that is, a weight of about 12 lb. 4 oz., is equal to the resistance of the cylinder; and consequently the half of it, or 6 lb. 2 oz., is that of the ball.

Or, the formula $\frac{anv^2}{4g}$ gives

$$\frac{.7854 \times 9 \times 1000 \times 16 \times 16}{144 \times 4 \times 16} =$$

196 oz., or 12 lb. 4 oz., for the resistance of the cylinder, or 6 lb. 2 oz. for that of the ball, the same as before.

Let now the resistance, so discovered, be divided by the weight of the body, and the quotient will shew the ratio of the retardation to the force of gravity. So if the said ball, of 3 inches diameter, is of cast iron, it will weigh nearly 61 ounces, or $3\frac{13}{16}$ lb.; and the resistance being 6 lb. 2 oz., or 98 ounces, therefore the resistance being to the gravity as 98 to 61, the retardation, or retarding force, will be $\frac{98}{61}$, or $1\frac{3}{5}$, the force of gravity being 1. Or thus; because a the area of a great circle of the ball, is $= pd^2$, where d is the diameter, and $p = .7854$, therefore the resistance to the ball is $m = \frac{pnd^2v^2}{8g}$; and because its solid content is $w = \frac{2}{3}pd^3$, and its weight $\frac{2}{3}Npd^3$, where N denotes its specific gravity, therefore dividing the resistance or motive force m by the weight w, gives $\frac{m}{w} = \frac{3nv^2}{16Ndg} = f$ the retardation, or retarding force, that of gravity being 1; which is therefore as the square of the velocity directly, and as the diameter inversely; and this is the reason why a large ball overcomes the resistance better than a small one, of the same density.

Resistance *of Fluid Mediums to the Motion of Falling Bodies*. A body freely descending in a fluid, is accelerated by the relative gravity of the body, (that is, the difference between its own absolute gravity and that of a like bulk of the fluid,) which continually acts upon it, yet not equably, as in a vacuum: the resistance of the fluid occasions a retardation, or diminution of acceleration, which diminution increases with the velocity of the body. Hence it happens, that there is a certain velocity, which is the greatest that a body can acquire by falling; for if its velocity is such, that the resistance arising from it becomes equal to the relative weight of the body, its motion can be no longer accelerated; for the motion here continually generated by the relative gravity, will be destroyed by the resistance; or the force of resistance will be equal to the relative gravity, and the body forced to go on equably: for, after the velocity is arrived at such a degree, that the resisting force is equal to the weight that urges it, it will increase no longer, and the globe must afterward continue to descend with that velocity uniformly. A body continually comes nearer and nearer to this greatest celerity, but can never attain accurately to it. Now, N and n being the specific gravities of the globe and fluid, $N - n$ will be the relative gravity of the globe in the fluid, and therefore $w = \frac{2}{3}pd^3(N - n)$ is the weight by which it is urged downward; also $m = \frac{pnd^2v^2}{8g}$ is the resistance, as above; therefore these two must be equal when the velocity can be no farther increased, or $m = w$, that is $\frac{pnd^2v^2}{8g} = \frac{2}{3}pd^3(N - n)$, or $nv^2 = \frac{16}{3}dg$ $(N - n)$; and hence $v = \sqrt{\frac{16}{3}dg \times \frac{N - n}{n}}$ is the said uniform or greatest velocity to which the body may attain; which is evidently the greater in the subduplicate proportion of v the diameter of the ball. But v is always $= \sqrt{4gfs}$, the velocity generated by any accelerative force f in describing the space s; which being compared with the former, it gives $s = \frac{4}{3}d$, when f is $= \frac{N - n}{n}$; that is, the greatest velocity is that which is generated by the accelerating force $\frac{N - n}{n}$ in passing over the space $\frac{4}{3}d$, or $\frac{4}{3}$ of the diameter of the ball, or it is equal to the velocity generated by gravity in describing the space $\frac{N - n}{n} \times \frac{4}{3}d$. For example; if the ball is of lead, which is about $11\frac{1}{4}$ times the density of water; then $N = 11\frac{1}{4}$, $n = 1$, $N - n = \frac{N - n}{n} = 10\frac{1}{4} = \frac{41}{4}$, and $\frac{N - n}{n} \times \frac{4}{3}d = \frac{4}{3}d = 13\frac{2}{3}d$; that is, the uniform or greatest velocity of a ball of lead, descending in water, is equal to that which a heavy body acquires by falling in vacuo through a space equal to $13\frac{2}{3}$ of the diameter of the ball, which velocity is $v = 2\sqrt{\frac{4}{3}dg \times \frac{N - n}{n}} = 2\sqrt{13\frac{2}{3}dg} = 8\sqrt{13\frac{2}{3}d}$ nearly, or 8 times the root of the same space.

Hence it appears, how soon small bodies come to their greatest or uniform velocity in descending in a fluid, as water, and how very small that velocity is; which explains the reason of the slow precipitation of mud, and small particles, in water; as also why, in precipitations, the larger and gross particles descend soonest, and the lowest.

Farther, where $N = n$, or the density of the fluid is equal to that of the body, then $N - n = 0$, consequently the velocity and distance descended are each nothing, and the body will just float in any part of the fluid.

Moreover, when the body is lighter than the fluid, then N is less than n, and $N - n$ becomes a negative quantity, or the force and motion tend the contrary way, that is, the ball will ascend up towards the top of the fluid by a motive force which is as $n - N$. In this case, then, the body ascending by the action of the fluid, is moved exactly by the same laws as a heavier body falling in the fluid. Wherever the body is placed, it is sustained by the fluid, and carried up with a force equal to the difference of the weight of a quantity of the fluid of the same bulk as the body, from the weight of the body; there is therefore a force which continually acts equably upon the body; by which not only the action of gravity of the body is counteracted, so as that it is not to be considered in this case; but the body is also carried upwards by a motion equably accelerated, in the same manner as a body heavier than a fluid descends by its relative gravity: but the equability of acceleration is destroyed in the same manner by the resistance, in the ascent of a body lighter than the fluid, as it is destroyed in the descent of a body that is heavier.

For the circumstances of the correspondent velocity, space, and time, &c. of a body moving in a fluid in which it is projected with a given velocity, or descending by its own weight, &c. see Dr. Hutton's Select Exercises, prop. 29, 30, 31, and 32, page 221, &c.

Resistance *of the Air*, is the force with which the motion of bodies, particularly of projectiles, is retarded by the opposition of the air or atmosphere. See Gunnery, Projectiles, &c.

The air being a fluid, the general laws of the resistance of fluids obtain in it; subject only to some variations and irregularities from the different degrees of density in the different stations or regions of the atmosphere.

The resistance of the air is chiefly of use in military projectiles, in order to allow for the differences caused in their flight and range by it. Before the time of Mr. Robins, it was thought that this resistance to the motion of such heavy bodies as iron balls and shells, was too inconsiderable to be regarded; and that the rules and conclusions derived from the common parabolic theory, were sufficiently exact for the common practice of gunnery. But that gentleman shewed, in his New Principles of Gunnery, that, so far from being inconsiderable, it is in reality enormously great, and by no means to be rejected without incurring the grossest errors; so much so, that balls or shells which range, at the most, in the air, to the distance of two or three miles, would in a vacuum range to 20 or 30 miles, or more. To determine the quantity of this resistance, in the case of different velocities, Mr. Robins discharged musket-balls, with various degrees of known velocity, against his balistic pendulums, placed at several different distances, and so discovered by experiment the quantity of velocity lost, when passing through those distances, or spaces of air, with the several known degrees of celerity. For having thus known, the velocity lost or destroyed, in passing over a certain space, in a certain time, (which time is very nearly equal to the quotient of the space divided by the medium velocity between the greatest and least, or between the velocity at the mouth of the gun and that at the pendulum); that is, knowing the velocity v, the space s, and time t; the resisting force is thence easily known, being equal to $\frac{vb}{2gt}$ or $\frac{vvb}{2gs}$, where b denotes the weight of the ball, and V the medium velocity above-mentioned. The balls employed upon this occasion by Mr. Robins, were leaden ones, of $\frac{1}{12}$ of a pound weight, and $\frac{3}{4}$ of an inch diameter; and to the medium velocity of

1600 feet, the resistance was 11 lb.,
1065 feet, - - - - - - it was $2\frac{4}{5}$;

but by the theory of Newton, before laid down, the former of these should be only $4\frac{1}{2}$ lb., and the latter 2 lb.; so that, in the former case the real resistance is more than double of that by the theory, being increased as 9 to 22; and in the lesser velocity the increase is from 2 to $2\frac{4}{5}$, or as 5 to 7 only.

Mr. Euler has shewn, that the common doctrine of resistance answers pretty well when the motion is not very swift, but in swift motions it gives the resistance less than it ought to be, on two accounts: 1. Because in quick motions, the air does not fill up the space behind the body fast enough to press on the hinder parts, to counterbalance the weight of the atmosphere on the fore part. 2. The density of the air before the ball being increased by the quick motion, will press more strongly on the fore part, and so will resist more than lighter air in its natural state. He has shewn that Mr. Robins has restrained his rule to velocities not exceeding 1670 feet per second; whereas had he extended it to greater velocities, the result must have been erroneous; and he gives another formula himself, and deduces conclusions differing from those of Mr. Robins.

Mr. Robins having proved that, in very great changes of velocity, the resistance does not accurately follow the duplicate ratio of the velocity, lays down two positions, which he thought might be of some service in the practice of artillery, till a more complete and accurate theory of resistance, and the changes of its augmentation, may be obtained. The first of these is, that till the velocity of the projectile surpasses 1100 or 1200 feet in a second, the resistance may be esteemed to be in the duplicate ratio of the velocity; and the second is, that when the velocity exceeds 1100 or 1200 feet, then the absolute quantity of the resistance will be near 3 times as great as it should be by a comparison with the smaller velocities. Upon these principles he proceeds in approximating to the actual ranges of pieces with small angles of elevations, viz. such as do not exceed 8° or 10°, which he sets down in a table, compared with their corresponding potential ranges. But we shall see presently that these positions are both without foundation; that there is no such thing as a sudden or abrupt change in the law of resistance, from the square of the velocity to one that gives a quantity three times as much; but that the change is slow and gradual, continually from the smallest to the highest velocities; and that the increased real resistance no where rises higher than to about double of that which Newton's theory gives it.

The subject of the resistance of the air, as begun by Robins, has been prosecuted by Dr. Hutton, to a very great extent and variety, both with the whirling-machine, and with cannon-balls of all sizes, from 1lb to 6lb. weight, as well as with figures of many other different shapes, both on the fore part and hind part of them, and with planes set at all varieties of angles of inclination to the path or motion of the same; from all which he has obtained the real resistance to bodies for all velocities, from 1 up to 2000 feet per second; together with the law of the resistance to the same body for all different velocities, and for different sizes with the same velocity, and also for all angles of inclination.

In this table are contained the resistances to several forms of bodies, when moved with several degrees of velocity, from three feet per second to twenty. The names of the bodies are at the tops of the columns, as also which end went foremost through the air; the different velocities are in the first column, and the resistances on the same line, in their several columns, in avoirdupois ounces and decimal parts. So on the first line are contained the resistances when the bodies move with a velocity of three feet in a second, viz. in the second column for the small hemisphere, of 4^3 inches diameter, its resistance .028 ounces when the flat side went foremost; in the third and fourth columns the resistances to a larger hemisphere, first with the flat side, and next the round side foremost; the diameter of this, as well as all the following figures, being $6\frac{2}{5}$ inches, and therefore the area of the great circle $= 32$ square inches, or $\frac{2}{9}$ of a square foot; then in the 5th and 6th columns are the resistances to a cone, first its vertex, and then its base foremost, the altitude of the cone being $6\frac{5}{8}$ inches, the same as the diameter of its base; in the seventh column the resistance to the end of the cylinder, and in the eighth, that against the whole globe or sphere. All the numbers shew the real weights which are equal to the resistances; and at the bottoms of the columns are placed proportional numbers, which shew the mean proportions of the resistances of all the figures to one another, with any velocity. Lastly, in the ninth column are placed the exponents of the power of the velocity which the resistances in the eighth column bear to each other, viz. which that of the ten-feet velocity bears to each of the following ones, the medium of all of them being as the 2.04 power of the velocity, that is, very little above the square or second power of the velocity, so far as the velocities in this table extend.

From this table the following inferences are easily deduced:

1. That the resistance is nearly in the same proportion as the surfaces; a small increase only taking place in the greater surfaces, and for the greater velocities. Thus, by comparing together the numbers in the second and third columns, for the bases of the two hemispheres, the areas of which bases are in the proportion of $17\frac{3}{4}$ to 32, or 5 to 9 very nearly, it appears that the numbers in those two columns, expressing the resistances, are nearly as 1 to 2 or 5 to 10, as far as the velocity of 12 feet; but after that, the resistances on the greater surface increase gradually more and more above that proportion.

2. The resistance to the same surface with different velocities, is, in these slow motions, nearly as the square of the velocity; but gradually increases more and more above that proportion as the velocity increases. This is manifest from all the columns: and the index of the power of the velocity is set down in the ninth column, for the resistances

in the eighth, the medium being 2.04; by which it appears that the resistance to the same body is, in these slow motions, as the 2.04 power of the velocity, or nearly as the square of it.

3. The round ends, and sharp ends, of solids, suffer less resistance than the flat or plane ends, of the same diameter; but the sharper end has not always the less resistance. Thus, the cylinder, and the flat ends of the hemisphere and cone, have more resistance, than the round or sharp ends of the same; but the round side of the hemisphere has less resistance than the sharper end of the cone.

4. The resistance on the base of the hemisphere, is to that on the round, or whole sphere, as $2\frac{1}{7}$ to 1, instead of 2 to 1, as the theory gives that relation. Also the experimented resistance, on each of these, is nearly $\frac{1}{4}$ more than the quantity assigned by the theory.

5. The resistance on the base of the cone, is to that on the vertex, nearly as $2\frac{3}{10}$ to 1; and in the same ratio is radius to the sine of the angle of inclination of the side of the cone to its path or axis. So that, in this instance, the resistance is directly as the sine of the angle of incidence, the transverse section being the same.

6. When the hinder parts of bodies are of different forms, the resistances are different, though the fore-parts are exactly alike and equal; owing probably to the different pressures of the air on the hinder parts. Thus, the resistance to the fore-part of the cylinder, is less than on the equal flat surface of the cone, or of the hemisphere; because the hinder part of the cylinder is more pressed or pushed by the following air than those of the other two figures; also, for the same reason, the base of the hemisphere suffers a less resistance than that of the cone, and the round side of the hemisphere less than the whole sphere.

Resistance of the fibres of solid bodies is more properly called cohesion.

RESOLUTION, in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis.

Resolution, in music, is when a canon or perpetual fugue is not written on a line, or in one part, but all the voices that are to follow the guide or first voice are written separately either in score, that is in separate lines, or in separate parts, with the pauses each is to observe, and in the proper tone to each.

RESPIRATION consists in drawing a certain quantity of air into the lungs, and throwing it out again alternately. Whenever this function is suspended, even for a very short time, the animal dies.

The fluid respired by animals is common atmospherical air; and it has been ascertained by experiment, that no other gaseous body with which we are acquainted, can be substituted for it. All the known gases have been tried; but they all prove fatal to the animal which is made to breathe them Gaseous bodies, as far as respiration is concerned, may be divided into two classes: 1. Unrespirable gases; 2. Respirable gases. See Air.

I. The gases belonging to the first class are of such a nature that they cannot be drawn into the lungs of an animal at all; the epiglottis closing spasmodically whenever they are applied to it. To this class belong carbonic acid, and probably all the other acid gases, as has been ascertained by the experiments of Pilatre de Rozier. Ammoniacal gas belongs to the same class; for the lungs of animals suffocated by it were found by Pilatre not to give a green colour to vegetable blues.

II. The gases belonging to the second class may be drawn into the lungs, and thrown out again, without any opposition from the respiratory organs; of course the animal is capable of respiring them. They may be divided into four subordinate classes; 1. The first set of gases occasion death immediately, but produce no visible change in the blood. They occasion the animal's death merely by depriving him of air, in the same way as he would be suffocated by being kept under water. The only gases which belong to this class are hydrogen and azotic. 2. The second set of gases occasion death immediately, but at the same time they produce certain changes in the blood, and therefore kill, not merely by depriving the animal of air, but by certain specific properties. The gases belonging to this class are carbureted hydrogen, sulphureted hydrogen, carbonic oxide, and perhaps also nitrous gas. 3. The third set of gases may be breathed for some time without destroying the animal; but death ensues at last, provided their action is long enough continued. To this class belong the nitrous oxide and oxygen gas. 4. The fourth set may be breathed any length of time without injuring the animal. Air is the only gaseous body belonging to this class.

It has been long known that an animal can only breathe a certain quantity of air for a limited time; after which it becomes the most deadly poison, and produces suffocation as effectually as the most noxious gas, or a total absence of air. It was suspected long ago, that this change is owing to the absorption of a part of the air; and Mayow made a number of very ingenious experiments in order to prove the fact. Dr. Priestley and Mr. Scheele demonstrated, that the quantity of oxygen gas in atmospheric air is diminished; and Lavoisier demonstrated, in 1776, that a quantity of carbonic acid gas, which did not previously exist in it, was found in air after it had been for some time respired. It was afterwards proved by Lavoisier, and many other philosophers, who confirmed and extended his facts, that no animal can live in air totally destitute of oxygen. Even fish, which do not sensibly respire, die very soon if the water in which they live is deprived of oxygen gas. Frogs, which can suspend their respiration at pleasure, die in about forty minutes, if the water in which they have been confined is covered over with oil. Insects and worms, as Vauquelin has proved, exhibit precisely the same phenomena. They require air as well as other animals, and die like them if they are deprived of it. They diminish the quantity of oxygen in the air in which they live, and give out, by respiration, the very same products as other animals. Worms, which are more retentive of life than most other animals, or at least not so much affected by poisonous gases, absorb every particle of the oxygen contained in the air in which they are confined, before they die. Mr. Vauquelin's experiments were made on the gryllus viridissimus, the limax flavus, and helix pomatia.

The quantity of air respired differs very much in different animals. Man and hot-blooded animals are under the necessity of breathing constantly; whereas amphibious animals have a certain power over respiration, and can suspend the function altogether for a limited time. Dr. Barclay has ascertained that these animals acquire a much greater command over their respiratory organs by habit. Fish do not breathe at all, and consume so little air, that the small portion of it held in solution by the water in which they swim is sufficient for them. It appears that the number of respirations made in a given time differs considerably in different men. Dr. Hales reckons them at 20 in a minute. A man on whom Dr. Menzies made experiments, breathed only 14 times in a minute. Mr. Davy informs us that he makes between 26 and 27 in a minute.

The quantity of air drawn in and emitted at every respiration must differ considerably with the size of the man and the capacity of his lungs. Dr. Menzies found that a man draws in at a medium 43.77 cubic inches of air at every inspiration. Dr. Goodwin has concluded, from his experiments, that, after a natural expiration, the mean quantity of air which remains in the lungs amounts to 109 cubic inches; but Menzies has endeavoured to prove that the number ought to have been 179. Mr. Davy has ascertained that his lungs, after a forced expiration, still retain 41 cubic inches of air; after a natural expiration they contain

	118 cubic inches
After a natural inspiration	135
After a forced inspiration	254
By a full forced expiration after a forced inspiration, he threw out	190 cubic inches
After a natural inspiration	78.5
After a natural expiration	67.5

Let us now endeavour to trace the changes produced by respiration. These are of two kinds, namely: 1. The changes produced upon the air respired. 2. Changes produced upon the blood exposed to this air. Each of these naturally claims our attention.

1. For our knowledge of the changes produced upon the air by respiration, we are chiefly indebted to Priestley, Cigna, Menzies, Lavoisier and Seguin, and Mr. Davy. These changes are the following: 1. Part of the air respired disappears. 2. It becomes impregnated with carbonic acid. 3. It is loaded with water in the state of vapour.

1. From the experiments of Dr. Menzies, it follows, that one-twentieth of the air inspired disappears in the lungs. This agrees pretty nearly with the experiments made with great care by Lavoisier; an account of which he was employed in drawing up when he was murdered by order of the French usurpers of that period. Neither do the experiments published lately by Mr. Davy, and which appear to have been performed with much precision, differ much from those of Dr. Menzies. According to Mr. Davy, about $\frac{1}{19}$th of the air inspired disappears during respiration.

Concerning the portion of the air which disappears, it has hitherto been the general opinion that it is the oxygen only, and that the azote remains the same after respiration as before it. These conclusions were the consequence of the experiments of Lavoisier, who announced the non-alteration of the azote of the atmosphere at a very early period of his researches. This conclusion seems to have been the consequence of the opinion which he entertained, that air is merely a mechanical mixture of the two gases, oxygen and azotic; for when he first adopted it, his apparatus was not delicate enough to measure small changes; and he does not appear to have afterwards examined the azotic residuum with much attention. Mr. Davy has rendered it probable that a portion of the azote of the air as well as its oxygen disappears during respiration.

According to Dr. Menzies, at every respiration 2.1885 cubic inches of oxygen gas are consumed. Now, 2.1885 cubic inches of that gas amount to 0.68669 grains troy. Supposing, with Hales, that a man makes 1200 respirations in an hour, the quantity of oxygen gas consumed in an hour will amount to 824.028 grains, and in 24 hours to 19776.672 grains, or 41.2104 ounces troy. This quantity exceeds that found by other chemists considerably; but the allowance of oxygen for every respiration is rather too great. Indeed, from the nature of Dr. Menzie's apparatus, it was scarcely possible to measure it accurately. According to the last experiments of Lavoisier and Seguin, a man, at an average, consumes in twenty-four hours, by respiration, 32.48437 ounces troy of oxygen gas: that is to say, that a quantity of oxygen gas, equal to that weight, disappears from the air which he respires in 24 hours. According to Mr. Davy, the average quantity of air which disappears during every respiration is 1.4 cubic inch; of which 0.2 are azote and 1.2 oxygen. This, allowing 26 respirations per minute, as was the case with Mr. Davy (the subject of the experiment), amounts in 24 hours to rather more than 38 ounces of air; or precisely to 4.68 ounces of azote, and 33.54 of oxygen. This does not differ far from the result obtained by Lavoisier, excepting in the azote, which the French chemist neglected altogether. We may consider it therefore as approximating to the truth as nearly as can be expected in the present state of the science.

2. That the air thrown out of the lungs contains carbonic acid, may be easily ascertained by blowing it through a tube into lime-water, which immediately becomes milky; and the bulk of the gas may be estimated by putting a portion of air from the lungs into a graduated jar standing over mercury, introducing a little barytic water, or pure soda, to absorb the carbonic acid, and observing the diminution of bulk in consequence of this absorption. According to Lavoisier, a man in 24 hours throws out from his lungs at an average about 15.73 ounces troy of carbonic acid. From the experiments of Mr. Davy, on the other hand, it follows, that at every expiration about 1.1 cubic inch of carbonic acid is emitted, which amounts in 24 hours to no less than 37 ounces. The difference between these two sets of experiments is enormous, and claims a more complete experimental investigation to determine, whether the proportion of this gas emitted by different individuals, or by the same individual at different times, does not differ essentially. This supposition is surely very probable, as it tallies with what we know to be the case in other excretions; and if it proves true, would throw more light upon the nature of respiration than any thing which has hitherto been ascertained. In the mean time, till farther experiments decide the point, we may consider Mr. Davy's conclusions as nearest the medium of the two, because they correspond with the earlier experiments of Lavoisier, and remove a very striking anomaly which appears when we compare Lavoisier's experiments on the respiration of the guinea-pig with those on the respiration of man. He put a guinea-pig into 708.989 grains troy of oxygen; and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen

gas now amounted only to	592.253 gr.
Consequently there had disappeared -	116.736
The carbonic acid gas formed was	130.472
The guinea-pig consumed in 24 hours -	5.8368 oz.
troy of oxygen gas, and emitted	6.5236 oz.

of carbonic acid gas. Man, on the other hand, consumes in the same time 32.48437 oz. of oxygen gas, and emits only 15.73 oz. of carbonic acid gas. The oxygen gas consumed by the pig is to the carbonic acid gas emitted as 1.00 : 1.12; whereas in man it is as 1.000 : 0.484. If we could depend upon the accuracy of each of these experiments, they would prove, beyond a doubt, that the changes produced by the respiration of the pig are different, at least in degree, from those produced in man; but it is more probable that some mistake has happened in one or other of the experiments.

3. It is not so easy to determine the proportion of water emitted from the lungs mixed with the air expired, as it is that of the carbonic acid. According to the experiments of Dr. Hales, it amounts in a day to 20.4 oz.; but his method was not susceptible of great accuracy. Mr. Lavoisier, on the other hand, estimates it at 28.55 ounces; but this proportion seems rather to have been the result of calculation than of any direct measurement. It can only be considered therefore as an approximation to the truth, and most probably a very imperfect one.

III. Let us now endeavour to ascertain the changes produced on the blood by respiration. The whole of the blood is propelled from the heart to the lungs, circulates through the vessels of that organ, and during that circulation it is exposed to the influence of the air which the animal is constantly drawing into the lungs. Now certain changes are produced upon it by this action, which have been partly traced by the experiments of Priestley, Cigna, Fourcroy, Hassenfratz, Beddoes, Watt, and above all by those of Mr. Davy. These changes, as far as we are acquainted with them, are the following: 1. The blood absorbs air. 2. It acquires a florid red colour, and the chyle disappears. 3. It emits carbonic acid, and perhaps carbon. 4. It emits water, and perhaps hydrogen.

As the azote which has separated from the air during respiration is not to be found in the products of respiration, we must conclude that it has been absorbed by the blood. The experiments of Mr. Davy have rendered it exceedingly probable that the air is absorbed unaltered by the blood; that it is afterwards decomposed by that liquid; and that the portion of azote which is useless is given out again, and mixed with the air in the lungs. The following facts render this opinion probable: When hydrogen gas is respired, no part of it is absorbed or disappears, nor are any positive changes produced on the blood. But when the gaseous oxide of azote is respired, it diminishes in quantity, while at the same time carbonic acid is evolved as usual, and a quantity of azotic gas makes its appearance. Now, as this azotic gas did not exist separately in the air before respiration, it must have been produced by the decomposition of the oxide of azote; but its quantity being much less than the azote contained in the oxide of azote which had disappeared, it follows that at least a part of this last gas had been absorbed by the blood unaltered; and if a part is thus absorbed, why not the whole? In that case the azotic gas must have been separated from the blood, in consequence of the subsequent decomposition of the oxide of azote absorbed. Now, as air is composed of precisely the same ingredients with the oxide of azote; and as a portion of the azote, as well as of the oxygen, of the air respired, disappears; it is reasonable to suppose that the air is absorbed by the blood, and that the azotic gas which is developed is thrown out of the blood in consequence of the decomposition of the air absorbed. But farther, if the oxygen of the air was alone absorbed by the blood during respiration while the azote remains unaltered, oxygen gas ought to answer the same purposes as air. This gas, however, cannot be respired without occasioning death at last; and when it is respired, the proportion of oxygen which disappears in a given time is much smaller than when the air is respired. Thus when 182 cubic inches of oxygen gas were breathed by Mr. Davy for half a minute, 11.4 cubic inches of the gas disappeared, whereas 15.6 cubic inches disappear in the same time when common air is respired. This is a demonstration that the whole of air is useful in respiration, and not merely its oxygen; and if so, the air must be absorbed.

2. It has been long known that the blood which flows in the veins is of a dark-reddish purple colour, whereas the arterial blood is of a florid scarlet colour. Lower observed that the colour of venous blood was converted into that of arterial during its passage through the lungs. No chyle can be distinguished by its white colour in the blood after it has passed through the lungs. The changes, then, which take place upon the appearance of the blood, are two: 1. It acquires a florid red colour; 2. the chyle totally disappears. Lower himself knew that the change was produced by the air, and Mayow attempted to prove that it was by absorbing a part of the air. But it was not till Dr. Priestley discovered that venous blood acquires a scarlet colour when put in contact with oxygen gas, and arterial blood a dark red colour when put in contact with hydrogen gas; or, which is the same thing, that oxygen gas instantly gives venous blood the colour of arterial, and hydrogen, on the

contrary, gives arterial blood the colour of venous blood; it was not till then that philosophers began to attempt any thing like an explanation of the phenomena of respiration.

The blood is a fluid of so complex a nature that it is not easy to ascertain the changes produced in it by exposure to different gases out of the body; and even if that could be done, we have no method of proving that the effects of these gaseous bodies upon the coagulated blood are the same as they would be on the blood in its natural state, circulating in the vessels of a living animal. The facts which have been ascertained are the following:

1st. It appears from the experiments of Priestley, Girtanner, and Hassenfratz, that when venous blood is exposed to oxygen gas confined over it, the blood instantly assumes a scarlet colour, and the gas is diminished in bulk; therefore part of the gas has been absorbed. Mr. Davy indeed could not perceive any sensible diminution of the bulk of the gas.

2d. The same change of colour takes place when blood is exposed to common air; and in that case the diminution of the bulk of the air is rather more sensible.

3d. Venous blood exposed to the action of azotic gas continues unaltered in colour; neither does any perceptible diminution of the gas ensue.

4th. Venous blood exposed to the action of nitrous gas becomes of a deep purple, and about one-eighth of the gas is absorbed.

5th. Venous blood exposed to nitrous oxide becomes of a brighter purple, especially on the surface, and a considerable portion of the gas is absorbed.

6th. Venous blood exposed to carbonic acid gas becomes of a brownish-red colour, much darker than usual, and the gas is slightly diminished in bulk.

7th. Carbureted hydrogen gas gives venous blood a fine red colour, a shade darker than oxygen gas does, as was first observed by Dr. Beddoes, and at the same time a small portion of the gas is absorbed. This gas has the property of preventing, or at least greatly retarding, the putrefaction of blood, as was first observed by Mr. Watt.

8th. When arterial blood is put in contact with azotic gas, or carbonic acid gas, it gradually assumes the dark colour of venous blood, as Dr. Priestley found. The same philosopher also observed, that arterial blood acquired the colour of venous blood when placed in vacuo. Consequently this alteration of colour is owing to some change which takes place in the blood itself, independant of any external agent.

The arterial blood becomes much more rapidly and deeply dark-coloured when it is left in contact with hydrogen gas placed above it. We must suppose, therefore, that the presence of this gas accelerates and increases the change, which would have taken place upon the blood without any external agent.

9th. If arterial blood is left in contact with oxygen gas, it gradually assumes the same dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer restore its scarlet colour. It is therefore only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occasions the dark colour, the blood loses the power of being affected by oxygen.

10th. Mr. Hassenfratz poured into venous blood a quantity of oxymuriatic acid; the blood was instantly decomposed, and assumed a deep and almost black colour. When he poured common muriatic acid into blood, the colour was not altered. Now oxymuriatic acid has the property of giving out its oxygen readily; consequently the black colour was owing to the instant combination of a part of the blood with oxygen.

Such are the phenomena produced upon the blood by the different gases out of the body; but the science is not far enough advanced at present to be able to explain them in a satisfactory manner. The obvious changes produced on the blood in the lungs by respiration, are the florid red colour, and the disappearing of the chyle.

3. That carbonic acid is emitted from the lungs during expiration, has been fully ascertained; but whether it is formed in the lungs, according to the theory of Lavoisier, by the combination of the oxygen of the air with carbon emitted by the blood, or is emitted ready-formed from the blood at the same time that the air is absorbed, is not so obvious; but the latter opinion is more probable, and indeed follows from the supposition that air is absorbed without decomposition.

4. It is much more reasonable to conclude that the watery vapour which exhales from the lungs along with the air expired, has been emitted from the blood, or from the vessels of the lungs, than to suppose with Lavoisier, that it is formed in the lungs by the combination of the oxygen of the air with hydrogen emitted from the blood.

From the preceding enumeration of facts, we may conclude that the following changes are produced by respiration: The blood, as it passes through the lungs, absorbs a portion of air, and carries it along with it through the blood-vessels. During the circulation this air is gradually decomposed by the blood, its oxygen and part of its azote entering into new combinations, while at the same time a portion of azote, of carbonic acid, and water, is evolved. When the blood returns to the lungs, it absorbs a new dose of air, and at the same time lets go the azotic gas, carbonic acid gas, and watery vapour, which had been formed during the circulation. The same changes are again repeated, and the same substances emitted, every time the blood comes to the lungs.

It is probable that, during a considerable part of the day, there is a constant influx of chyle into the blood; and we are certain that lymph is constantly flowing into it. Now it appears, from the most accurate observations hitherto made, that neither chyle nor lymph contains fibrina, which forms a very conspicuous part of the blood. This fibrina is employed to supply the waste of the muscles; the most active parts of the body, and therefore, in all probability, requiring the most frequent supply. Nor can it be doubted that it is employed for other useful purposes. The quantity of fibrina in the blood, then, must be constantly diminishing, and therefore new fabrina must be constantly formed. But the only substances out of which it can be formed are the chyle and lymph, neither of which contains it. There must, therefore, be a continual decomposition of the chyle and lymph going on in the blood-vessels, and a continual new formation of fibrina. Other substances also may be formed; but we are certain that this must be formed there, because it does not exist previously. Now, one great end of respiration must undoubtedly be, to assist this decomposition of chyle, and complete formation of blood.

It follows, from the experiments of Fourcroy, that fibrina contains more azote, and less hydrogen and carbon, than any of the other ingredients of the blood, and consequently also than any of the ingredients of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impossible to say: we are not sufficiently acquainted with the subject to be able to explain the process. But we can see at least, that carbon and hydrogen must be abstracted from that part of the chyle which is to be converted into fibrina; and we know, that these substances are actually thrown out by respiration. We may conclude, then, that one use of the air absorbed is to abstract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in such proportions that the remainder becomes fibrina: therefore one end of respiration is to form fibrina. Doubtless the other ingredients of the blood are also new-modified, though we know too little of the subject to throw any light upon it.

But the complete formation of blood is not the only advantage gained by respiration: the temperature of all animals depends upon it. It has been long known, that those animals which do not breathe have a temperature but very little superior to the medium in which they live. This is the case with fishes and many insects. Man, on the contrary, and quadrupeds which breathe, have a temperature considerably higher than the atmosphere: that of man is 98°. Birds, who breathe in proportion a still greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

These facts are sufficient to demonstrate, that the heat of animals depends upon respiration. But it was not till Dr. Black's doctrine of latent heat became known to the world, that any explanation of the cause of the temperature of breathing animals was attempted. That illustrious philosopher, whose discoveries form the basis upon which all the scientific part of chemistry has been reared, saw at once the light which his doctrine of latent heat threw upon this part of physiology, and he applied it very early to explain the temperature of animals.

According to him, part of the latent heat of the air inspired becomes sensible; and of course the temperature of the lungs, and the blood that passes through them, must be raised: and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanswerable objection: for if it was true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually as the distance from the lungs increases; which is not true. The theory, in consequence, was abandoned even by Dr. Black himself: at least he made no attempt to support it.

Crawford and Lavoisier, who considered all the changes operated by respiration as taking place in the lungs, accounted for the origin of animal heat almost precisely in the same manner with Dr. Black. According to them the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitted by the blood. During this combination, the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only sufficient to support the temperature of the body, but also to carry off the new-formed water in the state of vapour, and to raise considerably the temperature of the air inspired. According to these philosophers, then, the whole of the caloric which supports the temperature of the body is evolved in the lungs. Their theory accordingly was liable tothe same objection with Dr. Black's; but they obviated it in the following manner: Dr. Crawford found, that the specific caloric of arterial blood was 1.0300, while that of venous blood was only 0.8928. Hence he concluded, that the instant venous blood is changed into arterial blood, its specific caloric increases; consequently it requires an additional quantity of caloric to keep its temperature as high as it had been while venous blood. This addition is so great, that the whole new caloric evolved is employed; the temperature of the lungs must necessarily remain the same as that of the rest of the body. During the circulation, arterial blood is gradually converted into venous; consequently its specific caloric diminishes, and it must give out heat. This is the reason that the temperature of the extreme parts of the body does not diminish.

This explanation is certainly ingenious, but it is not quite satisfactory: for the difference in the specific caloric, granting it to be accurate, is too small to account for the great quantity of heat which must be evolved. It is evident that it must fall to the ground altogether, provided, as we have seen reason to suppose, that the carbonic acid gas and water are not formed in the lungs, but during the circulation.

Since the air enters the blood, and combines with it in the state of gas, it is evident that it will only part at first with some of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas, the azotic gas, and the water. For the reason that the carbonic acid leaves the blood at the instant that the air enters it, seems to be this: The air combines with the blood, and part of its caloric unites at the same instant to the carbonic acid, and converts it into gas: another portion converts the water into vapour. The rest of the caloric is evolved during the circulation, when the oxygen of the air combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs seems not only sufficient to carry off the carbonic acid and water, which the diminution of the specific caloric must facilitate; but it seems also to raise the temperature of the blood a little higher than it was before. For Mr. John Hunter constantly found, that the heat of the heart in animals was a degree higher than any other part of the body which he examined. Now this could scarcely happen, unless the temperature of the blood was somewhat raised during respiration.

Thus we have seen two uses which respiration seems to serve. The first is the completion of blood by the formation of fibrina; the second is the maintaining of the temperature of the body at a particular standard, notwithstanding the heat which is continually giving out to the colder surrounding bodies. But there is a third purpose, which explains why the animal is killed so suddenly when respiration is stopped. The circulation of the blood is absolutely necessary for the continuance of life. Now the blood is circulated in a great measure by the alternate contractions of the heart. It is necessary that the heart should contract regularly, otherwise the circulation could not go on. But the heart is stimulated to contract by the blood: and unless blood is made to undergo the change produced by respiration, it ceases almost instantaneously to stimulate. As the blood receives oxygen in the lungs, we may conclude that the presence of oxygen is necessary to its stimulating power.

REST, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous bodies; and, therefore, is opposed to motion. See MOTION.

REST, in music, the same with pause.

RESTAURATION, in architecture, the act of repairing those parts of a building that are gone to decay, in such a manner as to give it its original strength and beauty. See ARCHITECTURE.

RESTIO, a genus of the triandria order, in the diœcia class of plants. The male calyx is an ovate spike of membranaceous scales; the corolla is proper, hexapetalous, and persistent. The female calyx and corolla are as in the male; the germen is roundish, and is sex-sulcated; there are three erect and persistent styles; the capsule is roundish, with six plaits, and is rostrated and trilocular; the seeds are oblong and cylindrical. There are twenty-eight species, all natives of the Cape, some of them resembling rushes; and used for making brooms, thatching houses, &c.

RESTITUTION, of medals. See MEDAL.

RESTORATIVE. See MEDICINE, and MATERIA MEDICA.

RETAINER, in law, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

RETAINING FEE, the first fee given to a serjeant or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

RETARDATION, in physics, the act of diminishing the velocity of a moving body. See RESISTANCE.

RETE MIRABILE, in anatomy, a small plexus, or net-work, of vessels in the brain, surrounding the pituitary gland. See ANATOMY.

RETE MUCOSUM. See CUTIS.

RETENTION, is defined, by Mr. Locke, to be a faculty of the mind, whereby it keeps or retains those simple ideas it has once received by sensation or reflection.

RETENTION, is also used in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents. In this sense retention is opposed to evacuation and excretion.

RETICULA, or RETICULE, in astronomy, a contrivance for the exact measuring the quantity of eclipses.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel, placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent; of consequence, therefore, the diameter of the sun or moon is seen divided into twelve equal parts or digits; so that to find the quantity of the eclipse, there is nothing to do but to number the luminous and the dark parts. As a square reticule is only proper for the diameter, not for the circumference, of the luminary, it is sometimes made circular by drawing six concentric equidistant circles. This represents the phases of the eclipse perfectly.

RETINA, in anatomy, the expansion of the optic nerve on the internal surface of the eye, whereupon the images of objects being painted, are impressed, and by that means conveyed to the common sensory in the brain, where the mind views and contemplates their ideas. See OPTICS.

RETORT, in chemistry, a kind of hollow spherical vessel. See CHEMISTRY.

RETRAXIT, in law, is where a plaintiff comes in person to the court where his action is brought, and declares he will not proceed in it, in which case the action is barred for ever. A retraxit differs from a nonsuit in this, that it is always where the plaintiff or demandant is personally in court. See NONSUIT.

RETRENCHMENT, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gabions, barrels of earths, sandbags, and generally all things that can cover the men and stop the enemy. But retrenchment is more particularly applicable to a fosse bordered with a parapet; and a post fortified thus is called post retrenched, or strong post.

Retrenchments are either general or particular: general retrenchments are new fortifications made in a place besieged, to cover the besiegers when the enemy become masters of a lodgment on the fortification, that they may be in a condition of disputing the ground inch by inch, and putting a stop to the enemy's progress in expectation of relief.

RETROGRADATION, or RETROGRESSION, the act or effect of a thing moving backwards.

The retrograde motion of the planets is an apparent motion, whereby they seem, to an observer placed on the earth, to move backwards, or contrary to the signs. See ASTRONOMY.

RETURN, returna, or retorna, in law, is used in divers senses. 1. Return of writs by sheriffs and bailiffs is a certificate made by them to the court, of what they have done in relation to the execution of the writ directed to them. This is wrote on the back of the writ by the officer, who thus sends the writ back to the court from whence it issued, in order that it may be filed. 2. Return of a commission is a certificate or answer sent to the court from whence the commission issues, concerning what has been done by the commissioners. 3. Returns, or days in bank, are certain days in each term, appointed for the return of writs, &c. Thus Hilary term has four returns, viz. in the king's bench, on the day next after the octave, or eighth day after Hilary day: on the day next after the fifteenth day from St. Hilary: on the day after the purification: and on the next after the octave of the purification. In the common pleas, in eight days of St. Hilary: from the day of St. Hilary in fifteen days: on the day after the purification: in eight days of the purification. Easter term has five returns, viz. in the king's bench, on the day next after the fifteenth day from Easter: on the day next after one month from Easter: on the day next after five weeks from Easter: and on the day next after the day following ascension-day. In the common pleas, in fifteen days from the feast of Easter: in three weeks from the feast of Easter: in one month from Easter day: in five weeks from Easter day: on the day after the ascension-day. Trinity term has four returns, viz. on the day following the second day after Trinity: on the day following the eighth day after Trinity: on the day next after the fifteenth day from Trinity: on the day next after three weeks from Trinity. In the common pleas, on the day after Trinity: in eight days of Trinity: in fifteen days from Trinity: in three weeks from Trinity. Michaelmas term has six returns, viz. on the day next after three weeks from St. Michael: on the day next after one month of St. Michael: on the day following the second day after All-souls: on the day next after the second day after St. Martin: on the day following the octave of St. Martin: on the day next after 15 days of St. Martin. In the common pleas, in three weeks from St. Michael: in one month from St. Michael: on the day after All-souls: on the day after St. Martin: on the octave of St. Martin: in fifteen days from St. Martin. It is to be observed, that, as in the king's bench, all returns are to be made on some particular day of the week in each term, care must be taken not to make the writs out of that court returnable on a non-judicial day; such as Sunday, and All-saints, in Michaelmas term, the purification in Hilary, the ascension in Easter, and Midsummer-day except it should fall on the first day of Trinity term.

RETURNO HABENDO or RETURNUM AVERIORUM, is a writ which lies for a person who has avowed a distress by him made, and proved the same to be lawfully taken, for returning to him the cattle distrained which were before replevied by the party distrained upon surety given to prosecute.

RETURNUM IRREPLEGIABILE, a writ for the final return of cattle to the owner, when found to be unjustly distrained.

RETZIA, a genus of the monogynia order, in the pentandria class of plants, and in the 29th natural order, campanaceæ. The capsule is bilocular; the corolla cylindrical, and villous without; the stigma bifid. There is one species of the Cape, frutescent.

REVE, REEVE, or GREVE, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence shire-reve, sheriff, port-greve, &c.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVELS, entertainments of dancing, masking, acting comedies, farces, &c. antiently very frequent in the inns of court, and in noblemen's houses, but now disused. The officer who has the direction of the revels at court, is called the master of the revels.

REVENUE, PUBLIC, the yearly income appropriated to the expences of government. There are four different sources of public revenue: 1. The income derived from property vested in the public. 2. The emoluments of lucrative prerogatives annexed to the sovereignty. 3. Voluntary contributions from the people. 4. Taxes or imposts, not spontaneously given, but legally exacted. From one or other of these great sources all public revenue must arise.

The revenue of the kings of England consisted formerly of various branches which were inherited as the patrimony of the crown. Of these, the rents and profits of the demesne lands of the crown might alone have furnished a very considerable income, as there are few estates in the country which have not at some period or other since the Conquest been in the hands of the king. The custody of the lay revenues, lands, and tenements, of bishoprics during their vacancy, and of the temporalities of such abbeys as were of royal foundation, was made a productive source of revenue by some of the kings, who kept the sees a long time vacant to enjoy their income; Elizabeth kept the see of Ely vacant nineteen years for this purpose. First fruits and tenths of the livings of the clergy, were originally paid to the pope; but upon the destruction of his authority in England, were demanded by the king as his successor in clerical supremacy. The other branches of the antient revenue were, the profits of the military tenures; with the right of purveyance and pre-emption; and a claim to all property of which no other person had any legal pretension, such as treasure-trove or money-plate, or bullion found hidden in the earth; deodands, and forfeitures of lands and goods for offences; waifs, or goods stolen and thrown away by the thief in his flight; estrays, or valuable animals found wandering and the owner unknown; goods wrecked, if no proof could be made within a certain space of time who were the legal proprietors; the right to mines of silver and gold; and to certain fish, as whales and sturgeons, when either thrown on shore, or caught near the coast. These, with fines and forfeitures of various descriptions, and fees to the crown in a variety of legal matters, composed the ordinary revenue of the kings of England; but in the times of war, and on other occasions of extraordinary expence, it became necessary to have recourse to more general and efficient modes of raising money. The taxes thus occasionally collected were denominated Danegeld or Dane-money, escuage or scutage, hydage, talliage, tenths and fifteenths, and subsidies. Subsidies fell into disuse during the civil wars in the reign of Charles I. when the parliament introduced weekly and monthly assessments at a fixed sum upon each county, which were levied by a pound-rate both upon lands and personal estates. The scutages, hydage, talliage, subsidies, and periodical assessments, were all properly land-taxes, though not so generally known under that name as the more general imposition by which they have been superseded.

On the restoration of Charles II. it was deemed expedient to abolish the feudal rights and profits of wardship, marriage, livery, and purveyance: the propriety of this measure was generally acknowledged; and in order to make up the deficiency it would occasion in the king's revenue, an excise duty of fifteen pence per barrel upon all beer and ale, and a proportionable sum upon other liquors sold in the kingdom, was established. Excise duties had been introduced by the Long Parliament: about the same time also, considerable additions were made to the revenue of the customs; the post-office was established on a permanent footing, forming a new and very beneficial branch of public income; the land-tax was adopted on very nearly the plan on which it is at present assessed; and many improvements were made in other branches of the revenue. From this period the progress of the public revenue has been very rapid. The depreciation of the value of money, and the consequent advance in the price of all articles of consumption; the greater military and naval establishments which are kept up, and the accumulation of public debts for which an annual interest must be paid; have increased in an astonishing degree the sum requisite for defraying the yearly expences of government.

Sir John Sinclair, in his History of the Public Revenue, gives the following view of its amount at the commencement of each reign:

	Year.	Annual income.
William the Conqueror,	1066	£400,000
William Rufus	1087	350,000
Henry I. -	1100	300,000
Stephen -	1135	250,000
Henry II. -	1154	200,000
Richard I. -	1189	150,000
John - -	1199	100,000
Henry III. -	1214	80,000
Edward I. -	1272	150,000
Edward II. -	1307	100,000
Edward III. -	1347	154,139
Richard II. -	1377	130,000
Henry IV. -	1399	100,000
Henry V. -	1413	76,643
Henry VI. -	1422	64,976
Edward IV. -	1460	100,000
Edward V. -	1483	
Richard III. -	1483	
Henry VII. -	1485	400,000
Henry VIII. -	1509	800,000
Edward VI. -	1547	400,000
Mary -	1553	450,000
Elizabeth -	1558	500,000
James I. -	1602	600,000
Charles I. -	1625	895,819
The Commonwealth	1648	1,517,247
Charles II.		1,800,000
James II. -	1684	2,001,855
William III. -	1688	3,895,205
Queen Anne -	1706	5,691,803
George I. -	1714	6,762,643

	Year.	Annual income.
George II. -	1727	£8,522,540
George III. -	1760	8,800,000

The above statement shews a vast increase of the public revenue, particularly from the time of Charles I. but its progress since the year 1760, has been much more remarkable. In 1773 it amounted to 10,066,661*l.*; in 1780 it had advanced to 12,255,214*l.*; and in 1786 when the debts incurred by the American war had been fully provided for, it amounted to 15,096,112*l.* The increase of commerce during the peace, naturally improved such branches of the revenue as depended thereon; so that in 1791, its total produce was 16,712,000*l.* In the course of the war with the French Republic, the old taxes increased in produce, not only in consequence of an increased expenditure, which, to a certain extent, always increased the revenue, but also from an unexampled series of commercial and of general prosperity.

In former wars it was never expected, that the trade and manufactures of the country could equal their extent in peace; but at this period, various circumstances contributed to render Great Britain the emporium of Europe, and almost of the world. At home, the great increase of population, enabled the country to have in pay a greater number of seamen and soldiers than at any former period of its history, without experiencing any want of hands to carry on, to a greater extent than ever, agriculture, manufactures, and commerce. Great Britain also acquired abroad many valuable possessions of the French, the Dutch, and the Spaniards; and by the greatness of its maritime power held the complete dominion of the sea. Whilst it possessed these advantages, the continent of Europe was convulsed with war, unable to direct its attention to commercial industry, and had no market but England from which it could procure the productions of both the Indies.

It is not surprising, therefore, that under such favourable circumstances the wealth and income of the nation should increase, and consequently, that the old taxes should become more productive, which with the great number of new duties that it has been found necessary to impose, has raised the nett produce of the permanent and annual duties, composing the ordinary public revenue, to the vast sum of 35,314,158*l.* 10*s.* 4¼*d.*; in addition to which there are temporary taxes of very considerable amount, imposed for defraying part of the increased expenditure during the war, which made the total amount of the public revenue of Great Britain for the year ending 5th January 1806, as follows:

Nett produce of the

Customs -	£.7,192,889	15	11¼
Excise -	16,352,885	10	10
Stamps -	4,123,527	3	2
Land and Assessed Taxes -	6,261,778	19	4¼
Post-office -	1,237,004	19	10½
Pensions and Salaries	111,173	3	5¾
Hackney Coaches	26,454	14	10
Hawkers and Pedlars	8,444	2	9¾
Small branches of the hereditary revenue	157,373	11	10¾
War-taxes, Customs, and Excise -	8,992,377	13	8¼
Property-tax	£4,377,583	12	9½
Arrears of Income-duty, &c. -	49,403	6	9¾
Total	£.48,890,896	15	6½

In addition to the permanent and temporary taxes, constituting the public revenue, there are always certain incidental receipts applicable to the public service; such as the profits of lotteries, fees of the regulated exchequer-office, moneys repaid by public accountants, &c.

REVERBERATION, in physics, the act of a body repelling or reflecting another after its impinging on it.

REVERBERATORY, or REVERBERATING FURNACE. See FURNACE, Vol. I. p. 792, 2d column.

REVERSE *of a medal, coin,* &c. denotes the second or back side, in opposition to the head or principal figure. See MEDALS.

REVERSED, in heraldry, a thing turned backwards, or upside-down.

REVERSION, in law, is defined to be returning of lands, &c. into the possession of the donor, or his heirs. Reversion, in the law of England, has two significations; the one of which is an estate left, which continues during a particular estate in being; and the other is the returning of the land, &c. after the particular estate is ended; and it is further said to be an interest in lands, when the possession of it fails; or where the estate which was for a time parted with, returns to the grantors, or their heirs. But, according to the usual definition of a reversion, it is the residue of an estate left in the grantor, after a particular estate granted away ceases, continuing in the grantor of such an estate.

The difference between a remainder and a reversion, consists in this: that the remainder may belong to any man except the grantor; whereas the reversion returns to him who conveyed the lands, &c.

In order to render the doctrine of reversions easy, we shall give the following table; which shews the present value of one pound, to be received at the end of any number of years not exceeding forty; discounting at the rate of five, four, and three per cent. compound interest. See INTEREST.

Years.	Value at 5 per cent.	Value at 4 per cent.	Value at 3 per cent.
1	.9524	.9615	.9709
2	.9070	.9245	.9426
3	.8638	.8898	.9151
4	.8227	.8548	.8885
5	.7835	.8219	.8626
6	.7462	.7903	.8375
7	.7107	.7599	.8131
8	.6768	.7307	.7894
9	.6446	.7026	.7664
10	.6239	.6756	.7441
11	.5847	.6496	.7224
12	.5568	.6246	.7014
13	.5303	.6006	.6809
14	.5051	.5775	.6611
15	.4810	.5553	.6419
16	.4581	.5339	.6232
17	.4363	.5134	.6050
18	.4155	.4936	.5874
19	.3957	.4746	.5703
20	.3769	.4564	.5537
21	.3589	.4388	.5375
22	.3418	.4219	.5219
23	.3255	.4057	.5067
24	.3100	.3901	.4919
25	.2953	.3757	.4776
26	.2812	.3607	.4637
27	.2678	.3468	.4502
28	.2551	.3335	.4371
29	.2429	.3206	.4243
30	.2314	.3083	.4120
31	.2204	.2965	.4000
32	.2099	.2851	.3883
33	.1999	.2741	.3770
34	.1903	.2636	.3660
35	.1813	.2534	.3554
36	.1726	.2437	.3450
37	.1644	.2343	.3350
38	.1566	.2253	.3252
39	.1491	.2166	.3158
40	.1420	.2083	.3066

The use of the preceding table.—To find the present value of any sum to be received at the end of a given term of years, discounting at the rate of three, four, or five per cent. compound interest. Find by the above table the present value of one pound to be received at the end of the given term, which multiply by the number of pounds proposed (cutting off four figures from the product on account of the decimals), then the result will be the value sought. For example: the present value of 10,000*l.* to be received ten years hence, and the rate of interest five per cent. is equal to .6139 × 10,000 = 6139.0000 or 6139*l.* Again, the present value of 10.000*l.* due in ten years, the rate of interest being three per cent. is .7441 × 10,000 = 7441*l.*

REVERSION *of series,* in algebra, a kind of reversed operation of an infinite series.

REVIEW, in chancery, is used for a bill where a cause has been heard, and a decree thereon signed; but some error in law appearing upon the decree, or new matter being discovered after it was made, this bill is given for a fresh examination into the merits of the cause.

REVIEW, in war, is the appearance of an army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops.

REVIEW, is also the name of one kind of periodical publications, now too much prostituted (under the shelter of anonymous criticism) to the purposes of the malice of rival authors, and the petty artifice of interested booksellers.

REVISE, among printers, a second or third proof of a sheet to be printed; taken off in order to be compared with the last proof, to see whether all the mistakes marked in it are actually corrected.

REVIVOR, *bill of,* in chancery, is a bill for reviving a cause, where either of the parties dies after the bill and answer, and before the cause is heard; or if heard, before the decree is inrolled: in which case this bill must be brought, praying that the former proceeding may stand revived, and be put upon the same footing as at the time of the abatement.

REVOCATION, in law, signifies the recalling, or annulling and making void, some power, grant, deed, &c. made before.

RHACHITIS. See MEDICINE.

RHAMNUS, the *buckthorn*, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the forty-third order, dumosæ. The calyx is tubulous, with five minute scales surrounding the stamina; there is no corolla; the fruit is a berry. There are forty-two species; of which the most remarkable are, 1. The catharticus, or common purging buckthorn, growing naturally in some parts of Britain. This grows to the height of 12 or 14 feet, with many irregular branches at the extremities. The leaves are oval-lanceolate, finely serrated on the edges, their nerves converging together. The flowers grow in clusters, one in each footstalk, white, and in this species divided into four segments; the fruit is a round black herry, containing four seeds. The juice of the berries is a strong purgative, and is made use of for making the common syrup of buckthorn kept in the shops. The bark is emetic; the juice of the unripe berries with alum dyes yellow; the ripe ones a fine green; the bark dyes yellow. The green colour yielded by the berries, called by the French verdevissie, is much esteemed by miniature-painters. Of this species there are two varieties, viz. the dwarf buckthorn, a shrub of about a yard high, of a greenish colour, but of little show; and the long-leaved dwarf buckthorn, which is a larger shrub, with leaves somewhat larger, but in other respects very similar to the dwarf buckthorn. 2. The lotus has the leaves, prickles, flowers, and fruit, of the zizyphus or jubeb; only with this difference: that the fruit is here round, smaller, and more luscious, and at the same time the branches, like those of the paliurus, are neither so much jointed nor crooked. The fruit is in great repute, and tastes somewhat like gingerbread. The Arabs call it aneb enta el seedra, or the jubeb of the seedra: of which Olavus Celsius had so high an opinion, that he has described it as the dudaim of the Scriptures. This species is very common in the Jereede and other parts of Bombay; and has been supposed by some to be the same plant with that celebrated by Homer for its enchanting property; though the latter is more generally supposed to have been a species of diospyros. It is proper, however, to distinguish between both these shrubs and a herb often mentioned by the ancients under the name of lotus. They are also different from the Egyptian lotus described by Herodotus; for which see NYMPHÆA. 3. The frangula, or berry-bearing alder, is a deciduous shrub, a native of England and most of the northern parts of Europe, and affords several varieties. 4. The alpine, rough-leaved frangula, or berry-bearing alder, is also a deciduous shrub, and native of the Alps. It differs in no respect from the common sort, except that it has no thorns, and that it will grow to be rather taller, with tough, large, and double laciniated leaves. The smooth-leaved alpine frangula is a variety of this species, with smooth leaves and of a lower growth. 5. The paliurus, or thorn of Christ, is a deciduous shrub or tree, a native of Palestine, Spain, Portugal, and Italy. It will grow to nearly the height of 14 feet, and is armed with sharp thorns, two of which are situated at each joint, one is about half an inch long, straight, and upright; the other is scarcely half that length, and bent backward; and between them is the bud for next year's shoot. "This plant (says Hanbury) is undoubtedly the sort of which the crown of thorns for our Blessed Saviour was composed." 6. The common alaternus is an evergreen tree, and native of the south of Europe. There are several varieties of this species; the most remarkable of which are the broad-leaved and the jagged-leaved alaternus, which have all been confounded with the phillyrea. 7. The insectorius, or narrow-leaved buckthorn, is an evergreen shrub or tree, and native of Spain. It grows to the height of ten or twelve feet, and sends forth several branches from the bottom to the top. They are covered with a blackish or dark-coloured bark, and each of them is terminated by a long sharp thorn. The fruit continues on the trees all winter, making a beautiful appearance among the narrow clustered leaves at that season. 8. The oleoides, or olive-leaved buck horn, is an evergreen shrub, and native of Spain, and grows to the height of eight or ten feet. It sends forth numerous branches, each of which is terminated by a long sharp spine. The flowers are small, of a whitish-green colour, and are succeeded by round black berries.

RHAPIS, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the first order, palmæ. The calyx is a monophyllous trifid spatha; the corolla monopetalous and trifid. There are 2 species, viz. 1. Flabelliformis, or ground-ratan, a native of China; 2. Arundinacea, simple-leaved rhapis, a native of Carolina.

RHEA *Americana*, the American ostrich, in size is very little inferior to the common one; the bill is sloped not unlike that of a goose, being flat on the top and rounded at the end; the eyes are black, and the lids furnished with hairs; the head is rounded, and covered with downy feathers; the neck is two feet eight inches long, and feathered also; from the tip of one wing to that of the other extended, the length is eight feet; but from the want of continuity of the webs of the feathers, and their laxity of texture, the bird is unable to raise itself from the ground; it is, however, capable of greatly assisting itself by their motion in running, which it does very swiftly; the legs are stout, bare of feathers above the knees, and furnished with three toes, all placed forwards, each having a straight and stout claw as in the cassowary; on the heel is a callous knob, serving in place of a back toe; the general colour of the plumage is dull grey mixed with white, inclining to the latter on the under parts; the tail is very short, and not conspicuous, being entirely covered with long loose and floating feathers, having its origin from the lower part of the back and rump, and entirely covering it; the bill and legs are brown.

In respect to manners, it is said to be a general feeder, but more fond of flies, which it catches with great dexterity, and will also, like the common ostrich, swallow bits of iron and any other trash offered to it. In common with the ostrich of the Old World, it lays a number of eggs, from forty to sixty, in the sand, each of them holding a quart; but it differs from that bird in many particulars, especially in wanting the callosity of the sternum, and spars on the wing. With these last the common ostrich is known to defend itself; in defect of them, the bird here treated of uses the feet with such address, as to become at once a furious and dangerous antagonist. The female calls its young ones together with a kind of whistling note somewhat similar to that of a man; when young it is very tame, frequently following the first creature it meets with. The flesh of this bird is said to be very unpalatable. It is found in various parts of South America, from Patagonia to Guiana, and is known by the name of choique.

RHEEDIA, a genus of the monogynia order, in the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; there is no calyx; and the fruit is a trispermous berry. There is one species, a tree.

RHETORIC, in the most extensive sense of the word, denotes the art of composition, or that which enables us to apply language or speech to the best possible advantage. According to etymology, which often affords the most satisfactory explanation of words, it signifies the art of pouring forth a stream of sentiment, and communicating with fluency our feelings and thoughts to others. It is derived from the Greek ῥέω, to speak; and this again from ῥέω, to flow, or run like a river. Homer speaking of the eloquence of Nestor, says

Του καὶ ἀπὸ γλώσσης μέλιτος γλυκίων ῥέεν αὐδή.

Iliad I. line 49.

"And out of his mouth flowed an harangue sweeter than honey."

Taken in this point of view, rhetoric will comprehend all polite literature, poetry perhaps excepted, the belles-lettres of the French, the pathetic and pleasant of every kind; compositions whose aim and end is not so much to inform or satisfy the understanding, as to move, incline, and persuade, by addressing the imagination, the affections, and, in some measure, sensation itself.

There cannot be a better rule for composition, or one more plain and practical, than what is laid down by Cicero: "We are first to consider what is to be said; secondly, how; thirdly, in what words; and, lastly, how it is to be ornamented." We will venture to add, as a supplement even to Cicero, how far it ought to be ornamented.

The matter of any composition does not, properly speaking, fall under the cognizance of rhetoric, any farther than that there is an intimate connection between the subject and the style; and that the sentiments, whatever they are, naturally form, and raise or lower, swell or contract, the diction; on which we shall have occasion to make some observations when we speak of style.

But the second point in Cicero's rule, arrangement or order, is the most important, beyond all comparison, in every species of composition. It is in this, principally, that the mind of the author is seen; the process of his thoughts; the connection of his ideas with one another, and with his main design.

In every composition it is required that there should be some plan or object; just as in every thing we do or say, there is some purpose or intention. All written compositions may be divided into discourse or reasoning, poetry, and history, including both narration and description. In all, unity of design is indispensable. In discourse or reasoning, the object is to prove and impress on the mind some truth or series of truths. Here the bond of connection is cause and effect: the reason why such and such a thing must be so and so, and cannot be, or reasonably be supposed to be, otherwise. We believe certain things, it is true, on authority, or the testimony of others; but then it must be observed we judge of evidence by reason.

In respect to unity of design, there is a very near resemblance between epic poetry and history. The unity of design and action required in both differs not in kind but in degree. In epic or narrative poetry, the connection among the events related or described is more close and sensible. The narration is not carried on through such a length of time; and the actors hasten to some remarkable period which satisfies the curiosity of the reader. This difference between the epic poem and history, depends on that particular situation of the imagination and the passions which is supposed in the former. The imagination of both writer and reader is more enlivened, and the passions more inflamed, than in history, civil, political, or literary, biography, or any species of narration that confines itself to strict truth and reality. The same unity of design that runs through the epopeia, must also run through dramatic compositions, whether comic or tragic. Even in an ode, though the poet may be hurried from his plan for a time, or perhaps (as is sometimes the case, even with Horace) drop it altogether, there must appear some aim or design at least in the outset.

The connecting principle among the several events or circumstances which form the subject of a poem, may be very different according to the different designs of the poet. The Metamorphoses of Ovid is a work that embraces every fabulous transformation produced by the power of the gods. Thus, his plan is formed upon the connecting principle of resemblance. The subject of poetry forms a distinct article in the present work; but as unity of design is a principle common to all kinds of composition, it saves repetition to glance at poetical as well as rhetorical or prosaic composition, as far as this universal principle in all works of art is concerned.

As there may be different connecting principles in poetical, so also there may be in historical composition; and in every species of this composition, as in that, there must be some connecting principle, some bond of union among the different parts. Even in an epistle communicating or requiring information, there is a unity of design. In grave and serious letters, the subject is naturally and almost necessarily one; and even in the most light and familiar epistles there is this unity; that while they relate to a thousand particulars indifferent to all the world besides, they all of them relate to the situation, circumstances, and feelings, either of the writer, or the friend to whom the letter is addressed. Here the design is both interesting and closely attended to, in the eye of the parties concerned, even in proportion as the composition appears both uninteresting and desultory to others. In memoirs and anecdotes too, though apparently a mere collection of materials for building an edifice, there is an unity of design, in as much as they relate to some one person, or class of persons, some distinct time or period, or some place or country. Thus we have Memoirs of Frederic the Great of Prussia, Curious Collections relating to the State of Society in the middle Ages, and Anecdotes of the Court and Empire of Russia. In biography, the unity of design is manifest. That there is an unity of design in natural history, consisting chiefly in classification as well as description, needs no illustration.

But the grand province of history, and what is generally understood by the term, is,

History civil and political. The state, progress, or vicissitudes of society, in any particular period or country, in government, science, art, manners, and general civilization. The annalist, in his collections, or rather selections, (for it would be as absurd, as it is impossible, to record every thing) is guided by the connection of contiguity in time or place; the philosophical, the true, and legitimate historian, by that of cause and effect. "He traces the series of actions, according to their natural order, remounts to their secret springs and principles, and delineates their most remote consequences. He chooses for his subject a certain portion of that great chain of events which compose the history of mankind. Each link in this chain he endeavours to touch in his narration. Sometimes unavoidable ignorance renders all his attempts fruitless; sometimes he supplies by conjecture what is wanting in knowledge; and always he is sensible that the more unbroken the chain is, which he presents to his readers, the more perfect is his production. He sees that the knowledge of causes is not only the most satisfactory, (this relation or connection being the strongest of all); but also the most instructive: hence it is by this knowledge alone, that we are enabled to controul events and govern the future." Hume's Essays. Association of Ideas.

The matter of a composition being prepared, and the general design formed, the next thing to be considered is

The order of arrangement of the parts of a composition. And first of all, on this head, it may be observed that the authors of written compositions, usually, as is very natural and proper, set out with an *introduction*, whether in the form of a preface, or address to the reader, separate from the body of the work, or in the beginning of the work itself, without any distinction or separation. If the composition is addressed to the ear, the orator bespeaks the candid attention of his hearers by removing any prejudices they may be supposed to have conceived, and shewing the interest and importance of the subject of his discourse. He considers well what is the state or tone of mind of his hearers. To this he addresses himself in the first place; and endeavours to carry them along with him from one step or stage to another, till through a train of reasoning he arrives at the conclusion. There is a familiar illustration of the nature and use of an introduction or exordium to be met with every day in our house of commons; where the speakers often assure the house, when it begins to grow late, or when, from any other cause, it betrays symptoms of impatience or inattention, that "they will not trespass on their time for more than a very few minutes." In like manner the writer of a discourse or essay bespeaks the candid attention of his readers, by giving some general account of the nature of his design. If it is a question in history or philosophy, that is, concerning either matter of fact, or relations of ideas, he follows up his introduction immediately with a *statement* and history of the controversy. In some instances this statement and history are the only introduction; and, indeed, if the question is universally and highly interesting, there is no other introduction necessary: there can be none better. It is not only in doctrinal or didactic subjects that some introduction is required, but also even in most poetical, especially the epic, and historical compositions. The poet announces and gives an outline of his subject and design at the outset of his work, in order to interest his reader in its farther developement. He awakens curiosity by some of the most striking events in his narrative. Thus Homer tells you at once that he sings of the wrath of Achilles:

"That wrath which hurl'd to Pluto's dreary reign,
The souls of mighty chiefs, untimely slain."

Thus, in the Odyssey, he interests us in his design by a glimpse of the character of Ulysses, and his adventures after the reduction of Troy. Thus Virgil, having introduced himself to the reader, by letting him know who he was, in the first seven lines of the Æneid gives a summary view of the hardships, sufferings, and designs of Æneas. He introduces him first near the period when his designs were accomplished; designs that could not fail to interest every Roman; and afterwards shews, as in perspective, the more distant events, circumstances, and causes, that led to their formation, and crowned them with success. Thus Milton interests the Christian reader by letting him know in the outset of Paradise Lost, that he sings

"Of man's first disobedience, and the fruit
Of that forbidden tree whose mortal taste
Brought death into the world, and all our woe,
With loss of Eden, till one greater man
Restore us, and regain the blissful seat."

Thus, also, Virgil announces his different designs in the exordiums of his different books of Georgics; and thus also Thomson, in his Seasons.

In dramatic pieces there is no annunciation of a design, because suspense is kept up till the catastrophe. In tragedy, the design is, however, partly announced by the very name or names of the illustrious heroes or princes to whom it relates; and in comedy, the design is in some measure frequently expressed in the title; as in Love for Love; the Busybody; the Taming of the Shrew; the Careless Husband: the Jealous Wife; the School for Scandal, &c. &c.

With regard to that most extensive and important branch of composition, civil and political history, here too an introduction or annunciation of the design is as natural as in the epopeia; and it may be added, it is precisely of the same kind. The general effect or impression, the most striking event, truth, inference, or moral, that remains uppermost in the mind, after reviewing any series of events, and which serves as a bond of union among the occurrences and transactions which the historian involves in the stream of his narrative, impels him, it is supposed, to communicate his views, sentiments, and emotions, to others. It is natural therefore, and as it is natural it is expected, that the historian, in most cases, should introduce his work by glancing at the importance and the nature of his main design or object. Thus Livy, in his much admired and truly admirable preface, expresses his design of inquiring into the cause by which the Roman empire was extended over the world, and reached to such a pitch of greatness that it seemed to totter under its own weight. The design was noble and grand, and the annunciation of it could not but draw attention. Thus Sallust chooses for a subject the Catilinarian conspiracy, because it was "in the highest degree memorable on account of the singularity, and the danger involved in the enormous crime." Thus also he writes an account of the Jugurthine war: "first, because it was great and terrible, and the success various; and, secondly, because a check was then given, for the first time, to the insolence of the nobility." In both cases he makes an apology for retiring from political life, and employing himself in the composition of history.

2. In didactic discourse, the speaker or writer, after an introduction, *states* the truth which he proposes to prove or illustrate, and also the chief propositions or points, by the establishment of which he forms his conclusion. This serves to keep up the attention of the hearer or reader to the main object, and the connection or dependance of this on the intermediate or subordinate propositions; but the heads must not be too many, for otherwise they would run into the embarrasment of multiplicity, and in fact cease to be heads.

3. As to the disposition of arguments, or order of placing them, it is generally thought the best economy to place the weaker (if they are not rather to be omitted altogether) in the middle; and such as are stronger, in order to excite attention and draw esteem, partly in the beginning, and, as what is heard or read last commonly dwells longest on the mind, partly at the end. But if there are only two arguments, the rule is to place the stronger first, and then the weaker; and after that to resume and insist principally on the former.

4. In matters that admit of doubt or disputation, it is proper, after proving your own position, to refute the arguments urged by gainsayers or adversaries.

Lastly, comes the conclusion of the discourse or treatise, or whatever it is called; which consists of two parts; a recapitulation of the principal arguments or circumstances, and an address to the passions.

In oratory too, it is observed by rhetoricians, besides the parts just mentioned, there is room for

Digression, transition, and amplification. Where a subject is of itself but unentertaining and dry, the mind is relieved and restored to the exertion of its powers by amusing digression; which, however, it is evident, should neither be too frequent nor too long, except, indeed, when the cause is very bad, and almost hopeless; for, in this case, it is good economy to divert attention as much as possible from too nice a scrutiny into the subject.

Transitions are defined to be "forms in speech by which orators tell their hearers in a few words both what they have said already, and what they next design to say." When a discourse consists of a considerable number of parts, and especially when these are of considerable length, transitions are necessary; but sometimes, in passing from one thing to another, a very general hint is sufficient.

By amplification the orater enlarges and expatiates on a subject in such a manner as to represent it in the fullest and most comprehensive view, and so that it may strike the mind in the most forcible manner, and influence the passions. He ascends from things particular to things general, or descends from things general to things particular, and an enumeration of instances; he connects his position with a concurrence of various causes, and on the other hand, with a variety of effects; he places things in the light of contrast; he amplifies facts from the circumstances of time, place, manner, and the like.

As to the order of historical composition, the general effect or impression of the whole of the materials, which serves as a bond of union among the events which the historian weaves into his narrative, serves him also as a clue by which he winds back and unfolds the concatenation of circumstances which produced the grand event, or effect or effects, that first interested and induced him to transmit the whole to posterity. Every legitimate history, as well as epic poem, springs from some important truth or moral, as from its root; and shoots forth into various branches, twigs, leaves, and flowers, until, in due time, it reproduces, in a manner, that fruit which gave it birth; until by some issue or catastrophe, it impresses on the mind the doctrine, truth, or moral, which forms its principal object; and as the epic poet, after briefly announcing the subject that fires his soul, does not fly directly and rapidly to the end he has in view, but on the contrary, keeps long on the wing, and aims in his flight to warm the mind and to gratify its vast desires by frequent views of the grandeur, magnificence, and beauty of nature; so the historian diversifies his narrative by incidents, circumstances, and episodes; various scenes are opened, various actors introduced, with various characters and manners.

As the historian is guided by his taste and judgment in the selection of his materials, so according to the measure of his taste and judgment he assigns them their place. To the order in which an infinite variety of materials may be best arranged under the eye that contemplates them, the rules or resources of rhetoric scarcely extend. If nothing more, yet certainly nothing better, can be said on the subject of order in general, than what has been said near two thousand years ago by Horace, and is still in every mouth:

Sumite materiam, vestris qui scribitis, æquam
Viribus; et versate diu quid ferre recusent,
Quid valeant humeri, cui lecta potenter erit res,
Nec facundia deseret hunc, nec lucidus ordo.

De Arte Poetica, line 38—41.

"O ye writers! make choice of a subject suited to your powers; and ponder long on what your shoulders are able or not able to bear. Where there is a good choice, neither eloquence nor method will ever be wanting."

This is in truth the quintessence of rhetoric. There is, however, as Horace immediately observes, room for taste or judgment, in the preferring of one order or arrangement of particulars to another. "The efficacy and grace of method consists in knowing when to say any thing, whether on the present, or whether, though pertinent enough to the present, it may not with advantage be reserved to some future occasion." The same just and accomplished critic says elsewhere, more generally,

Scribendi rectè, sapere est principium et fons.

De Arte Poetica, l. 299.

"The principle and spring of fine writing is good sense."

As good sense will prescribe just order in composition, so also it will suggest just and suitable sentiments.

Style. A style should correspond to the tone of mind of the author, and the tone and temper he wishes to communicate to others. The connection between the tone of mind and the diction is described by the same Roman poet, whose great master was Aristotle, in so just and connected a manner, that we shall content ourselves on the present point with quoting a small part of Horace, and referring our readers to the poet himself. "Every subject should have a style appropriate to itself. A comic subject does not admit of the pomp of a tragic strain; nor the bloody supper of Thyestes bear to be told in the simple numbers of comedy. Sometimes, however, comedy raises her voice; and Chremes roused to anger and rage, gives vent to his sentiments in a high strain of indignation. Tragedians, on the contrary, lower their style to express their grief. It is natural for men to laugh with those that laugh, and weep with those that weep; the human countenance to vary with the sympathetic emotions of joy or sorrow. If you would have me shed tears, you must first shed them yourself. Plaintive words are most correspondent with a dejected look. Threats come well from a person in anger, mirth and pleasantry from a facetious temper, and grave remonstrances from a severe character." See De Arte Poetica, line 90—118.

Though these observations are made here with a reference to poetical, it is manifest that the spirit of them (namely, that language should be suited to the nature of the subject) is applicable to all composition; to common prose, to oratorical prose, to philosophical or didactic prose, and to historical prose; on each of which it is proposed to make a few observations.

But we premise a few remarks on the qualities that should prevail in style in general. They may be reduced to these: 1, purity; 2, perspicuity; 3, vigour; 4, harmony; 5, dignity; 6, beauty.

Purity consists in the choice of such words and phraseology as are agreeable to the most general and approved usuage of the language in which we write. The offences against purity are accordingly reduced to two, barbarisms and solecisms; the former of which respects single words, the latter their construction in sentences. The words and phrases that occur in writings, though in many respects estimable, are not all of them pure, but only such as are agreeable to the usage of the most distinguished writers; writers whose works descend from one generation and one age to another, without losing aught of their original interest and beauty. Thus, our English translation of the Bible is written in a pure style; so are the Spectators and other writings of Mr. Addison, and the letters and prefaces of Mr. Pope. To purity of style it is necessary not only that it is formed according to the rules of philosophical or universal grammar, but according to the particular genius or idiom of the language in which we write. Thus, though "I see a voice" is allowable in Greek, and occurs in the twelfth verse of the first chapter of the Revelations, it would not be allowed in any original composition in English. Hence as it depends on the purity of a style whether a composition shall not become soon unintelligible and die away, or penetrate to posterity, and be transmitted to future ages, this, of all the good qualities of style, may be considered as the most important. In the present day, in our country, there seems to be a wanton introduction not only of phrases degraded by common and trivial use, but of what may be called vulgar slang (if slang is not indeed an example itself of the abuse here noted), into the debates in parliament, and consequently newspapers, pamphlets, and a deluge of ephemeral histories. What reader of the next century will understand, "it is a hoax; meeting my idea; making up my mind; blinking the question," &c. &c.? Even Mr. Hume, and other writers of note, especially among his countrymen the Scots, trespass greatly against purity, when they admit into their English style not only Scotticisms, against which they are now pretty generally on their guard, but so many Latin idioms and Gallicisms. As to Latinity, this too has been used even immoderately by our great lxicog rapher Dr. Johnson.

Perspicuity, like purity, consists partly in single words, and partly in their construction. As to single words, their force and propriety are to be judged of from the usage of the most generally approved writers at the period of our writing. For through length of time, words lose their original signification, and assume a new one, which then becomes their proper sense. Thus the word knave antiently signified a servant. In an old English version of the New Testament we find, "Paul, the knave of Jesus Christ." The proper and precise meaning of words, nearly synonimous, is to be distinguished with accuracy. For example: mercy and pity are sometimes confounded; though mercy is, properly speaking, exercised towards an offender, and pity towards one in distress. But though the meaning of all the words in a sentence, considered by themselves, may be very obvious, yet the sense of the whole may be obscured by a disorderly arrangement, of which a very apt and curious example is given by Quinctilian. "A certain man ordered in his will that his heir should erect for him a statue holding a spear made of gold" A question here of great consequence to the heir arose from the ambiguity of the expression; as it admitted of doubt whether the words, "made of gold," were to be applied to the statue, or to the spear. Care, therefore, must be taken to dispose both the words and parts of a sentence in such a manner as best agrees with their mutual connection and dependance on each other.

Vigour, or energy of style, depends chiefly on brevity and a judicious use of tropes and figures. Brevity consists in the use of general propositions and general terms, which comprehend a great number of particulars, the enumeration of which weakens a style, as in the material world bodies are weakened by dilatation. The use of figurative language, or tropes and figures, is, perhaps, still more connected with dignity and beauty of style; but we embrace the first occasion of making some remarks on its nature.

The antient rhetoricians, who were fond of multiplying distinctions to great excess, distinguished a trope from a figure; understanding by a trope a change in the usual meaning of words, and by a figure a change or deviation from the usual mode of constructing them in sentences; but they are generally confounded by the most accurate and purest writers. Both these kinds of changes, however, may be comprehended, even according to etymology, under the word trope, which in Greek signifies a turn. As no language contains a sufficient number of proper words to express all the different conceptions of our minds, tropes were introduced to supply the deficiency; to express the various ideas that occurred from different associations and analogies which sprung up in the mind on viewing things in different lights, and comparing them with one another; required this aid to language. Among the principal tropes are metaphor, allegory, metonymy, irony, hyperbole, climax, inversion, antithesis, interrogation, exclamation, apostrophe, and prosopopeia or personification.

A *metaphor* is a comparison or simile, without any words implying comparison, and commonly reduced to a single word. To say of a man that he is like a fox or a lion, is a simile; that he is a fox or a lion, a metaphor. A metaphor taken from a simile which ascribes life and action to things inanimate, and lengthened out into many, or even several circumstances, is an *allegory*. In metaphors and allegories, care should be taken that the same image or kind of trope is carried throughout the whole. A mixture of metaphors is one of the most common, as well as greatest, deformities in composition, though by a very little attention it might certainly be very easily avoided. An instance of this, amounting even to what we call a bull, occurs in Mr. Hume, though on the whole a correct writer: "The farther we mount up into antiquity, the more do we find mankind plunged into idolatry." Nat. Hist. Religion, section I. On the other hand, a minute attention to resemblances sometimes leads a writer into studiedand far-fetched conceits; than which, to a true taste, delighting only in what is great, and, consequently simple, there can be nothing more disgusting.

A *metonymy* is a trope which changes the names of things that are naturally though not essentially united, as the cause for the effect, or the effect for the cause, &c. Thus, Mars is put for war, Ceres for corn, and Bacchus for wine:

Implentur veteris Bacchi pinguisque farinæ.
Virg.

Thus, in common discourse, it is usual to say, "this is such a person's hand, I know his hand," that is his writing.

Irony is a trope in which one thing is said, and the contrary intended. The subjects of irony are all manner of vices and follies, which are sometimes exposed in this way more effectually than by the most serious reasoning. In irony, the author assumes the air of believing as others do; but by a developement of the ground of belief, of the pro and the con, brings out the truth, and leaves the reader or hearer himself to draw the conclusion. We listen to the still voice of our own reason and conscience, and secretly condemn our own tenets or our own conduct, when pride and passion might raise a mist that might shade us from the light that should emanate from others. This figure of speech was used so much by Socrates, that he got the appellation of Eiron or Droll. The most perfect specimen of irony in the English language is Swift's Directions to Servants.

Hyperbole, which exceeds the bounds of strict truth, and represents things as either greater or less than they really are, is the boldest of all tropes. The representation, however, is made in such a manner as not to impose on the hearer. It has always a very considerable effect, even when most extravagant; as it shews, at least, the opinion entertained by the speaker on any subject, in a very strong light; it is a natural expression of enlivened emotion. We meet with hyperboles even in the Scripture: "I bear you record," says St. Paul in his Epistle to the Galatians, chap. iv. "that if it had been possible ye would have plucked out your own eyes and given them to me;" and the Evangelist John concludes his Gospel in these words. "There are also many things that Jesus did, which if they should be written every one, I suppose that even the world itself could not contain the books that should be written."

Climax is a compound sentence in which the different parts or clauses are closely connected, and rise gradually in importance above one another. We have an admirable example of this trope in that passage of sacred writ, where it is said of the joys of Heaven, "that eye hath not seen, nor ear heard, neither hath it entered into the heart of man to conceive." We hear more things than we see; but the imagination can form to itself an infinitude of things that do not fall under the cognizance of any of our senses. The following is also an excellent exemplification of the climax: "Whom God did predestinate, them he also called; and whom he called, them he also justified; and whom he justified, them he also glorified." Rom. viii. 30. But there may be a climax of periods as well as of sentences. Here also we are furnished with the most apt and splendid examples by the Scriptures. "For scarcely for a righteous man will one die, yet, peradventure, for a good man, some would even dare to die; but God commendeth his love towards us, in that while we were yet sinners, Christ died for us." Rom. v. 7, 8. The contrary of a climax is the bathos, as some have called it after Pope, or the sinking in composition, otherwise called an anticlimax; from which miserable deformity and disgrace, authors might be saved by a small exertion of attention and common sense:

"And thou, Dalhousie, thou great god of war,
Lieutenant-colonel to the earl of Mar."
Blackmore.

Yet this was not burlesque; it was intended for a serious and heroic poem. In some instances it would appear as if writers were at pains to study the art of sinking. Mr. Lane Macgregor Buchannan meaning to do great honour, and to extol the isle of Skye, says, that "some of the vassals (of the great families there) are colonels, majors, captains, and lieutenants." Macgregor Buchannan's Defence of the Highlanders, page 86.

Dr. Swift observed the just order in composition when he makes one tell the ladies who entertained him in a tavern,

> "Had ye been cunning stagers,
> Yourselves might have been treated
> By captains and by majors."

But it is not only in writers of the very lowest class that we find the anticlimax. We have an example of this in Dr. Reid, where he says "the emotion raised by grand objects is awful, solemn, and serious." The order of these epithets should just have been inverted.

Inversion is a figure in speech in which the usual arrangement of words in a sentence, or of sentences in a compound sentence or period, is inverted. For an example of the first kind, see Nisus in the Æneid, exclaiming,

> "Me, me: adsum qui feci; in me convertite ferrum."
>
> Æn. lib. ix.

> "Me, me: here I am who have done the deed; on me turn your steel."

Under extreme agitation the usual process both of thought and speech is interrupted. The language of passion is broken and incoherent. The impassioned mind rushes directly to the principal figure or object; from the action to the agent; from the attribute to the substance. Of the second kind, where the mind, though unruffled and discomposed, and thinking in a regular train, is animated to great conceptions, we have an instance in the first sentence of the Paradise Lost.

Antithesis is the illustration of one thing by another, and is, we presume, universally understood. If an explanation or illustration of it by an example is wanted, the reader is referred to the three last verses of the fourth chapter of St. Paul's Second Epistle to the Corinthians. There cannot be a happier example, and the book referred to is in every hand. Neither is it necessary to explain *interrogation* or *exclamation*. The meaning of these figures is obvious from the very names to every one, and examples occur at every turn in all kinds of composition and discourse, written or spoken.

In an *apostrophe*, the speaker breaks off from the series of his discourse, and addresses himself to some particular person, present or absent, living or dead, or even to inanimate objects. A fine example of apostrophe occurs in the second book of Paradise Lost, line 681—7:

> "Whence, and what art thou, execrable shape?"

And a still finer in the fourth book, line 720—35:

> "Thus at their shady lodge arrived, both stood,
> Both turn'd, and under open sky ador'd
> The God that made both sky, and earth, and heaven,
> Which they beheld; the moon's resplendent globe,
> And starry pole: 'Thou also mad'st the night,
> Maker omnipotent, and thou the day," &c.

See also the much admired apostrophe of Æneas to his departed father Anchises:

> "Heu! genitorem, omnis curæ casûsque levamen,
> Amitto Anchisem; hic me, pater optime, fessum
> Deseris, heu!"
>
> Æneid, lib. iii. line 710.

"Here, alas! I lose my father Anchises, the soother of all my cares, my relief in every misfortune. Here, O thou best of parents! you left me overcome with fatigue," &c.

Prosopopeia, or personification, either introduces an absent person as speaking, or one who is dead as if he was alive and present, or speech is attributed to some inanimate being. The sublimest example of the prosopopeia that ever was, or can possibly be exhibited, is found in the book of Job. Job, on a review of his own actions, appeals from the criticisms of men to the judgment of God. "Then the Lord answered Job out of the whirlwind and said," &c. as in the Book of Job, chap. xxxviii—xli. 7.

There is not any figure better adapted to the purposes of the higher species of eloquence, that is, the pathetic and sublime, than the prosopopeia, by which the poet or orator may call all nature to his aid; but if it was introduced in any other than a highly impassioned strain, it would lose its effect, and even appear ridiculous. In all things the speaker is to consider well for what he has prepared the hearer.

Did our limits admit, most of our readers, and among these the most cultivated and intelligent, would excuse us from following the antient rhetoricians, and those who tread in their footsteps, through all the tropes and figures to which the subtle genius of Greece, wielding the most copious and pliant language that ever was known amongst men, has given a kind of nominal existence: synecdoche, antonomasia, litotes, euphemismus, catachresis, metalepsis, asyndeton, pleonasmus, polysyndeton, antanaclasis, ploce, epizeuxis, &c. &c. &c.

On looking over this long catalogue of words, of so little practical use, we are almost inclined to say with Butler,—

> "For all a rhetorician's rules
> But teach him how to name his tools."

All tropes and figures rise naturally out of a well stored and brilliant imagination, an earnestness to establish the truth, and the diffusive influence of the passions. The poet, the orator, animated himself, extends animation, life, and action to every object that comes in his way. To return now to vigour or energy of style.

How much this is promoted by figurative language will appear from this, that in proportion as the mind labours with any vivid emotion or conception it is prone to give it a substantial form, to clothe it in metaphorical language. Now, a lively trope conveys not only a livelier, but often a juster idea of an object, than can be communicated by proper words in the most copious periphrasis. Thus, when Virgil calls the two Scipios two thunderbolts of war, he exhibits a more lively image of the rapid force and success of their arms, than could have been given in plain words. The next-mentioned great quality of style, was

Harmony. As in music we require sound, uniformity, variety, and proportion, so we also require them, not only in compositions addressed to the ear, but also in written compositions; for the reader conceives of what he reads as if it was spoken by himself or by others. His ear, in some measure, runs over the page as well as his eye. Numbers are not confined to poetry: there is a rythmus, though of a more slow and sober kind, in prose. Here too we require sonorousness, uniformity, and variety of cadence. For these purposes there must be an intermixture of long and short words, and long and short sentences. As to the modulation of the voice in speaking, as well as of pronunciation, looks, and gesture, these belong to elocution, of which we have many professors. The sum and substance of elocution is, to speak from feeling.—Si vis me flere, &c.

The harmony of style is very much promoted by the use and invention of compound words, which any one is at liberty to contrive at pleasure, if he adheres to the analogy of language. As an example of all this, we produce a beautiful passage, which is a rural and domestic scene in Thomson's Seasons:

> ———— "In the pond
> The finely-chequered duck before her train
> Rows garrulous. The stately-sailing swan
> Gives out his snowy plumage to the gale,
> And arching proud his neck, with oary feet
> Bears forward fierce, and guards his osier-isle
> Protective of his young. The turkey nigh,
> Loud-threatening reddens; while the peacock spreads
> His every-coloured glory to the sun,
> And swims in radiant majesty along."
>
> Spring, line 773—32.

Nothing can be more harmonious.

Sublimity of style consists in language suitable to sublime emotions. Nay, the more plain and simple the images appear, the greater the surprise, wonder, and astonishment. It sometimes darts forth with rapidity and vehemence, and sometimes reposes on the tranquillity of general views, exhibited in general terms.

As an instance of the power of simplicity in every species of composition that aims at the sublime and beautiful, we may contrast the style and manner of Michael Angelo and Zuccero in painting. Michael Angelo painted his figures naked; Frederico Zuccero, who painted the cupola of Florence, peopled it with a multitude of both sexes, extremely well dressed in the fashion of the times. The style of Michael Angelo was sublime and beautiful; that of Zuccero little, and in process of time ridiculous.

Instances of the sublime are so abundant in poetry both sacred and profane, and in oratory, at least by that of the antients, that we leave the task of illustration on these two heads to our readers; but description and narration too, in prose, also admit of the sublime; and here it will be found to consist chiefly in the selection of the grandest objects and most striking circumstances, figurative language, brevity, and, what is very closely connected with brevity, the use of general terms. For example: Dr. J. Heylyn, speaking of John the Baptist, says "prophecy, vision, and miracle concurred to render his birth illustrious, and draw attention, and raise expectation with regard to a person so signally the care of heaven. Soon after his birth he was carried into the wilderness to escape (as antient writers relate), the slaughter which Herod made of the Jewish children. Thus the desart became the school in which he learnt temperance. Want taught him abstinence, till, grace and reason gaining strength, he embraced that mortification with a deliberate choice, in which he had been engaged for the preservation of his life." Heylyn's Theolog. Lectures, vol. 1, p. 13.

Another example of the sublime in narration. "It is true, king Ferdinand had laid some foundation for the future greatness of Spain; for whilst his perpetual negotiations and intrigues formed him many able statesmen and ministers, his long and successful wars in the kingdom of Grenada, and in Italy, had introduced such excellent order and discipline into his armies, and particularly amongst his infantry, that either in suffering hardships, or in battle, the world could not shew its equal. These were the arms which, at Pavia and on the Elbe, crowned so great a work of fortune with the highest pitch of glory; and afterwards in the Low Countries, supported for a while its declining greatness." Political Works of Fletcher of Saltown, page 133.

Beauty of style may be said in general to consist of an union of purity, perspicuity, a moderate use of tropes, and in harmony. In the energetic or pathetic, and the sublime, the mind being in a state of emotion and agitation, is naturally hurried into figurative language. In the contemplation or description of those objects which give birth to emotions of beauty, we are calm and collected, and are not, as in the pathetic and sublime, constrained to make use of tropes and figures; yet it is in this calm state only that we are at leisure to make use of some of the finest and most expressive tropes and figures, as antitheses, allegories, similes, and metaphors, if carried beyond a single word. How much this figurative language contributes to the beauty of style and composition is exemplified by judge Blackstone in the following: "Benevolences extorted from the subject, the arbitrary imprisonments for refusal, the exertion of martial law in time of peace, and other domestic grievances clouded the morning of that misguided prince's (Charles I.) reign, which, though its noon began a little to brighten, at last went down in blood, and left the whole kingdom in darkness." Blackstone's Commentaries.

Of the metaphors which ascribe life and action to inanimate beings, we have an example in a metaphorical description of the steam engine. "The steam engine, approaching to the nature of a perpetuum mobile, or rather an animal, incapable of lassitude as of sensation, produces coals, moves machines, works metals, and is certainly the noblest drudge that was ever employed by the hand of art. Thus we put a hook in the nose of the leviathan (Job xli.); thus we play with him as with a child, and take him for a servant for ever; thus we subdue nature, and derive aid and comfort from the elements of earthquakes." Anal. Review, Retrospect of the Active World, Feb. 1797. The metaphor being aptly kept up, givs beauty to the two first sentences here; the last rises into a style somewhat higher.

Having thus treated briefly of the principal qualities of style in general, we come now to speak of the varieties of style most proper for the different kinds of prosaic composition, which may be divided into four: the familiar or colloquial, the rhetorical, the philosophical, and the historical.

The *familiar* or *colloquial* style, is that of common but genteel and polished conversation, of letters, meaning epistles, and of written dialogue, comical or serious. The style of conversation should be simple and plain: no elaborate sentences; no affectation of wit or eloquence; scarcely any great attention to grammatical accuracy: at least that attention should never be visible. To repeat what has been said ungrammatically, for the purpose of correcting himself, as is sometimes done, is most miserably pedantic. The greatest powers of conversation are shewn in following the turn and tone of conversation, in an ingenious and pleasing manner, not in leading it. It is easy to pour forth a shew of knowledge, if one is allowed to lead the conversation; not so easy to illustrate any topic extempore. The former shews only reading, the latter learning. There are a kind of babblers, familiarly called cocks of the conversation, who, having furnished and loaded their memories at home in set conversations or literary meetings, however denominated, say their lessons to an auditory, admiring, if stupid, disgusted, if intelligent. This great metropolis abounds in illustrations of this position. In letters greater care and preparation is both allowable and required. Of epistolary writing we have some excellent models in the correspondence of Swift, Pope, Arbuthnot, Gay, and other wits of their time; but none, either in England or France, for ease, elegance, and energy of style, are to be at all compared with the epistles of Cicero, Brutus, and other Romans of high rank and cultivated genius. As to written dialogue, the style of this seems to hold a middle place between the familiar or colloquial, and the rhetorical, which may be divided into three kinds; the style proper for short and popular essays, that for a popular assembly, the senate or bar, and that for the pulpit. The subjects of the first-mentioned species of writing, are moral, critical, or entertaining; the thoughts must be condensed and close, and every thing to be said, said briefly, because the whole work itself is but short, and supposed to be read at some moment of leisure. The style should be plain and simple, that every one may understand it; yet so elegant that no one may be disgusted with it. The best model of essays, in every respect, is Mr. Addison's papers in the Spectator, Guardian, and Freeholder.

The style of eloquence proper for a public oration, admits of every possible variation or inflection, according to the tone and temper of the auditory, to what they can bear, or may be brought to bear, and enter into or sympathize with, familiar, easy and in a humorous strain, or serious, solemn, rapid, impassioned, and vehement. This rule holds in some degree in speeches addressed to juries and to our house of commons. In the house of peers, the supreme judges in civil cases, and that branch of the legislature which moderates and checks any effervescence that may appear in the resolutions of the more popular branch, the eloquence of the orator should be, as it indeed is, more guarded, chastened, and sober.

We have instances of the most pathetic and sublime eloquence among savage tribes. Witness the celebrated address of Logan, an Indian chief, to lord Dunmore, governor of Virginia. The Greek and Roman orators united the bold and unconfined tone of the rudest, with the knowledge and art of the most refined nations. The circumstances of climate, and form of government, in which there were but few laws, and the appeal in many, nay, most cases, made to equity, account, in some measure at least, for the difference between antient and modern oratory. But the more an English orator can elevate his tone, and by a rapid stream of passion throw his audience into a kind of dream, or temporary belief of every thing that is said, the nearer he arrives at the summit of excellence.

The eloquence of the pulpit is altogether of a serious, solemn, pathetic, and sublime cast. Here no rhetorical artifices are either admissible or necessary; the preacher must speak the truth, and nothing but the truth; and the truths predicated are so interesting and important, so sublime and awful, that they are not to be heightened by any exaggerations of fancy. The language of scripture too, is infinitely more energetic and impressive than that of any human composition. The preacher has only to speak from believing, and to convince his audience that he really believes what he says, by the simplicity, purity, and heavenly-mindedness of his character and conduct. This is the charm that gave efficacy to the preaching of the apostles and Christian fathers, and success to the missionaries from Rome in modern times. Order in every discourse is indispensable; and this will arise out of the subject, treated in a rational and sensible manner. Never was any English divine more esteemed and admired, either as a preacher or a man, than Dr. Heylyn, a prebendary of Westminster, above quoted. In what did his oratory consist? "The principal rule of his eloquence, (says the writer of a preface to his posthumous works) was to carry his real thoughts to the pulpit, and to preach as if he was speaking to his congregation; while his action, and every look and gesture was adapted to the nature and variations of his subject."

Philosophical or didactic style. In pure mathematics, and experimental philosophy illustrated by mathematics, nothing more is requisite or proper than purity and perspicuity. But moral philosophy, which is a mixture of facts and principles, as natural philosophy is of facts and mathematics, admits of great eloquence, and should be made as entertaining as possible.

Historical style. History may be divided into three heads. 1. Natural history. 2. Anecdotes, memoirs, annals, and books of voyages and travels, all of them containing, at least, materials for history. 3. Civil history, or the condition, actions, vicissitudes, and improvements of men united in society under different forms of governments. To each of these there is a style in some measure appropriate, though in all the style should vary with the variations of the subject. In natural history, purity or propriety, and perspicuity of style is sufficient; nothing more is required. But descriptions of natural appearances also admit of elegance, and even sublimity, as well as accuracy; of which Buffon furnishes a pleasing example. It is a pity that so charming a writer should indulge so much in the propensity of his countrymen to mere theory. His obtrusion of theory, often whimsical and extravagant, is, indeed, so offensive to a sober inquirer into the productions of nature, that a strict and severe philosopher is rather better pleased with the plainness of Pliny, and of Linnæus, whose views of both plants and animals are at once so accurate and so extensive. As to anecdotes, annals, memoirs, voyages and travels, as there is no other design in such writing than to treasure up any thing interesting that comes in his way, no other qualities of style are requisite than exactness and perspicuity, though here too the style naturally rises or falls with the objects described, and facts which are recorded. In voyages and travels it rises sometimes into the dignity and sublimity of epic poetry; when, under the arctic circle, on the borders of the Frozen Ocean, nature languishes, vegetation ceases, the elements alone appear, and the "earth is contemplated only as forming a part of the solar system." Signore Giuseppo Acerbi's Travels to the North Cape.—When, at the stupendous falls of the Clyde, "doubling a tuft of wood, you are struck at once with the awful scene which suddenly bursts upon your sight, your organs of perception are hurried along, and partake of the turbulence of the roaring waters. The powers of recollection remain suspended by this sudden shock, and it is not till after a considerable time that you are enabled to contemplate the sublime horrors of this awful scene." Newte's Tour in England and Scotland.

On viewing the same scene, the reverend Mr. Hall also raises his tone. "After seeing the smoke ascending for more than a mile as I advanced, I first heard and then saw the Clyde roaring and raging as if provoked at resistance. The question started in my mind, is nature then so bustling and noisy in her operations, so tumultuous, rapid and impetuous?" Tour in Scotland, by an unusual Route, with a Trip to the Orkneys and Hebrides.

Civil history. This being addressed to the whole world, to every country and every age, to philosophers, legislators, kings and princes, the general style, air or tone, should be that of dignity; but it should not be always elevated. It should vary with the particular subject which is treated, which may be done without descending to meanness.

The historian, Robertson, whose greatest excellence, and a great excellence it is, consists in the close and beautiful order in which he deduces events from the causes that gave them birth, is, perhaps, not sufficiently various in his style. He never sits with you in a garden chair, or by the fireside; he never descends from his pulpit.

It is to be observed, however, that some designs admit of greater variety of style than others. The Abbé St. Real, who has given so fine a specimen of the concise and rapid style, in his History of the Conspiracy of Venice, had not an opportunity, and could not with propriety vary either his matter or his manner, so much as Mr. Hume in his History of England, with occasional Sketches of the principal States of Europe for seven hundred Years. Neither Thucydides nor Sallust, confined by their designs to particular events and a very short period of time, could expatiate at leisure on a variety of subjects like Herodotus, who records the common transactions of the Greeks and Barbarians for a long period of time; the scenes of whose narrative is extended over a considerable part of the three grand divisions of the antient world, and to a period of two centuries. Thucydides writes the history of a single war, and the scene of the events is confined generally to the narrow spot of Greece. The histories of Sallust are still more circumscribed in respect of both action and space. The curiosity of the reader being strongly excited by the contemplation of one great event, and approaching catastrophe, the dignified conciseness of Thucydides and Sallust, forms the greatest beauty. The arrangement of Thucydides, who divides his work into summers and winters, is very faulty; but his style for his subject and design is admirable; yet it must be admitted that the style proper for different plans or designs in history, admits of modification from the different geniuses of different historians. The retreat of the ten thousand Greeks was a single event, and embraced but a small portion of time; yet the easy, graceful, and sweetly-flowing narrative of Xenophon, the Athenian bee, is also admirable in its kind, though different from the charming simplicity and melody of Herodotus, the energy of Thucydides, the brevity of Sallust, the majesty of Livy, and his happy imitators among the moderns, Mariana and Buchannan, and the elegant purity and precision of Julius Cæsar. In a word, though there are certain general qualities of style suited to a general subject, that style is agreeably tinctured, not deformed by a diversity of genius.

Non una quidem
Nec diversa tamen qualis decet esse sororum.

Now, to conclude, by recapitulating what has been now said on the present article. As speech is the power, so rhetoric is the art of communicating our sentiments in the fullest and most impressive manner. As the ends for which we communicate our sentiments are various, the form, style, or manner of discourse, spoken or written, is different also; corresponding with the emotions to be expressed and excited, whether of surprise, complacency, admiration, wonder, astonishment, sympathy, ridicule, honour, or shame. The first and cardinal point in every composition, is to be master of the subject; to have a clear conception of all that we wish to say. "Out of the fulness of the heart the mouth speaketh." As the analogies of language were formed before the rules of grammar, so literary works were composed before the canons of criticism and rules of rhetoric. These rules are of more use in preventing the false glare of turgidity, fustian, bombast, and conceit, than of avail to inspire the most excellent qualities of speaking or writing. An attention to these rules will obviate blemishes. A well-informed understanding, with a lively imagination and a feeling heart, are the grand sources of excellent composition; a taste for which may be farther improved by a constant perusal of the best models, in the same manner that the constant contemplation of the best pictures forms insensibly a just and nice taste for painting; but it should never be forgotten that the highest excellences of style are never attained where the fire of imagination is smothered by an anxious fear of offending against any rules; and that the absence of faults and blemishes is dearly bought by the absence of elegance and every beauty.

RHEUM, a thin serous humour, occasionally oozing out of the glands about the mouth and throat.

RHEUM, *rhubarb*, a genus of the monogynia order, in the enneandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is sexfid and persistent; and there is one triquetrous seed. There are seven species. The most noted are:

1. The rhaponticum, or common rhubarb, has a large, thick, fleshy, branching, deep-striking root, yellowish within; crowned by very large, roundish, heart-shaped, smooth leaves, on thick, slightly-furrowed, foot-stalks; and an upright strong stem, two or three feet high, terminated by thick close spikes of white flowers. It grows in Thrace and Scythia, but has been long in the English gardens. Its root affords a gentle purge. It is, however, of inferior quality to some of the following sorts; but its young stalks in spring being cut and peeled, are used for tarts.

2. The palmatum (see Plate Nat. Hist. fig. 346.), palmated-leaved true Chinese rhubarb, has a thick fleshy root, yellow within; crowned with very large palmated leaves, being deeply divided into acuminated segments, expanded like an open hand; upright stems, five or six feet high or more, terminated by large spikes of flowers. This is now proved to be the true foreign rhubarb, the purgative quality of which is well known.

3. The compactum, or Tartarian rhubarb, has a large, fleshy, branched root, yellow within; crowned by very large, heart-shaped somewhat lobated, sharply indented, smooth leaves, and an upright large stem, five or six feet high, branching above; having all the branches terminated by nodding panicles of white flowers. This has been supposed to be the true rhubarb; which, however, though of superior quality to some sorts, is accounted inferior to the rheum palmatum.

4. The undulatum, undulated or waved-leaved Chinese rhubarb, has a thick, branchy, deep-striking root, yellow within; crowned with large, oblong, undulate, somewhat hairy leaves, having equal foot-stalks, and an upright firm stem, four feet high, terminated by long loose spikes of white flowers.

5. The ribes, or currant rhubarb of Mount Libanus, has a thick fleshy root, very broad leaves, full of granulated protuberances, and with equal foot-stalks and upright firm stems, three or four feet high, terminated by spikes of flowers, succeeded by berry-like seeds, being surrounded by a purple pulp. All these plants are perennial in root, and the

leaves and stalks are annual. The roots being thick, fleshy, generally divided, strike deep into the ground; of a brownish colour without and yellow within; the leaves rise in the spring, generally come up in a large head folded together, gradually expanding themselves, having thick foot-stalks; and grow from one to two feet high, or more, in length and breadth, spreading all round: amidst them rise the flower-stems, attaining their full height in June, when they flower, and are succeeded by large triangular seeds, ripening in August. Some plants of each sort merit culture in gardens for variety; they will effect a singularity with their luxuriant foliage, spikes, and flowers; and, as medical plants, they demand culture both for private and public use.

They are generally propagated by seeds sown in autumn soon after they are ripe, or early in the spring, in any open bed of light deep earth. Scatter the seeds thinly, either by broad-cast all over the surface, and raked well in, or in shallow drills a foot and a half distance, covering them near an inch deep. The plants will rise in the spring, but not flower till the second or third year: when they are come up two or three inches high, thin them to eight or ten inches, and clear out all weeds; though those designed always to stand should afterwards be hoed out to a foot and a half or two feet distance; observing if any are required for the pleasure-ground, &c. for variety, they should be transplanted where they are to remain in autumn, when their leaves decay, or early in spring, before they shoot: the others remaining where sown must have the ground kept clean between them; and in autumn, when the leaves and stalks decay, cut them down, and slightly dig the ground between the rows of plants, repeating the same work every year. The roots remaining, they increase in size annually; and in the second or third year many of them will shoot up stalks, flower, and perfect seeds; and in three or four years the roots will be arrived to a large size, though older roots are generally preferable for medical use.

Two sorts of rhubarb are met with in the shops. The first is imported from Turkey and Russia, in roundish pieces freed from the bark, with a hole through the middle of each: they are externally of a yellowish colour, and on cutting appear variegated with lively reddish streaks. The other, which is less esteemed, comes immediately from the East Indies, in longish pieces, harder, heavier, and more compact than the foregoing. The first sort, unless kept very dry, is apt to grow mouldy and worm-eaten; the second is less subject to these inconveniences. Some of the more industrious artists are said to fill up the worm-holes with certain mixtures, and to colour the outside of the damaged pieces with powder of the finer sorts of rhubarb, and sometimes with cheaper materials: this is often so nicely done as effectually to impose upon the buyer, unless he very carefully examines each piece. The marks of good rhubarb are, that it is firm and solid, but not flinty; that it is easily pulverable, and appears when powdered of a fine bright yellow colour; that, upon being chewed, it imparts to the spittle a saffron tinge, without proving slimy or mucilaginous in the mouth. Its taste is subacrid, bitterish, and somewhat astringent; the smell lightly aromatic.

Rhubarb is a mild cathartic, which operates without violence or irritation, and may be given with safety even to pregnant women and children. Besides its purgative quality, it is celebrated for an astringent one, by which it strengthens the tone of the stomach and intestines, and proves useful in diarrhœas and disorders proceeding from a laxity of the fibres. Rhubarb in substance operates more powerfully as a cathartic than any of the preparations of it. Watery tinctures purge more than the spirituous ones; whilst the latter contain in greater perfection the aromatic, astringent, and corroborating virtues of the rhubarb. The dose, when intended as a purgative, is from a scruple to a drachm or more.

The Turkey rhubarb is, among us, universally preferred to the East India sort, though this last is for some purposes at least equal to the other; it is manifestly more astringent, but has somewhat less of an aromatic flavour. Tinctures drawn from both with rectified spirit have nearly the same taste: on distilling off the menstruum, the extract left from the tincture of the East India rhubarb proved considerably the strongest.

The method of curing the true rhubarb is as follows: Take the roots up when the stalks are withering or dying away, clean from the earth with a dry brush, cut them in small pieces of about four or five inches in breadth, and about two in depth, taking away all the bark, and make a hole in the middle, and string them on packthread, keeping every piece apart; and every morning, if the weather is clear and fine, place them in the open part of the garden on stages erected by fixing small posts about six feet high in the ground, and six feet asunder, into which fix horizontal pegs, about a foot apart, beginning at the top; and the rhubarb being strung crosswise on small poles, place them on these pegs; so that, if it should rain, you could easily remove each pole with the suspended pieces into any covered place. Never suffer them to be out at night, as the damps at this season would be apt to mould them.

RHEUMATISM. See Medicine.

RHEXIA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking with those of the 17th order calycanthemæ. The calyx is quadrifid with four petals inserted into it; the antheræ are declining; the capsule is quadrilocular, within the belly of the calyx. There are 13 species, annuals and shrubs of America.

RHINANTHUS, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadrifid, and ventricose; the capsule bilocular, obtuse, and compressed. There are eight species, among which is the yellow rattle, a weed well known.

RHINOCEROS, a genus of quadrupeds of the order belluæ: the generic character is, horn solid, perennial, conical, seated on the nose.

1. Rhinoceros unicornis, single-horned rhinoceros. The rhinoceros is the largest of land animals, the elephant alone excepted. It is of a highly uncouth and awkward form. The back, instead of rising, as in the elephant, sinks in considerably: the head is moderately large and long; the upper lip protrudes or hangs over the lower in the form of a lengthened tip; and, being extremely pliable, answers the end of a small proboscis, and is useful to the animal in catching hold of the shoots of vegetables, &c. and delivering them into the mouth. On the nose is situated a very strong, slightly curved, sharp-pointed horn, which, in the full-grown animal, is sometimes three feet in length, and eighteen inches in circumference at the base. The mouth has four cutting-teeth, which are placed at each corner of each jaw; there are also six grinders in each jaw, of which the first is remote from the cutting-teeth. (In strict propriety it may be doubted whether the four teeth first mentioned should be called by the title of cutting-teeth.) The ears are moderately large, upright, and pointed; the eyes small; the skin naked, rough, and tuberculated, or marked with very numerous, large, callous granulations; it is destitute of hair, except a few straggling and very coarse bristles on some parts of the head, &c. About the neck the skin is disposed into several large plaits or folds; another fold of the same kind passes from the shoulders to the fore legs, and another from the hind part of the back to the thighs; the tail is slender, flattened at the end, and covered on the sides with very stiff and thick black hairs; the belly is somewhat pendulous, or shaped like that of a hog; the legs very short, strong, and thick; the feet marked into three large hoofs, all standing forwards. The general height of the rhinoceros is about eight feet; but it is said that some have been seen in Sumatra and Java which nearly equalled the size of the elephant, though they appeared lower on account of the sinking back, the pendulous abdomen, and short legs.

The rhinoceros is a native of several parts of India, as well as of the islands of Java, Sumatra, &c. This animal falls far short of the elephant in sagacity and docility. It is, however, of a quiet and inoffensive disposition, but very furious and dangerous when provoked or attacked: he is said to run with great swiftness, and, from his strength and impenetrable covering, is capable of rushing with resistless violence through woods and obstacles of every kind; the trees bending like twigs while he passes between them. In general habits and manner of feeding, the rhinoceros resembles the elephant, residing in cool sequestered spots, near waters, and in shady woods: it delights in rolling occasionally in the mud, in the manner of a hog. Its skin is so hard as to be impenetrable by any common weapons, except on the belly: it is even said, that, in order to shoot a full-grown rhinoceros of advanced age, it is necessary to make use of iron bullets; those of lead having been known to be flattened against the skin.

The bones of the rhinoceros, like those of the elephant, are often found in a fossil state in various parts of the world; and in the year 1772, an entire rhinoceros was found buried in the banks of a Siberian river, in the antient frozen soil, with the skin, tendons, and some of the flesh, in the highest state of preservation. It was discovered in the sandy banks of the river Witim, which falls into the Lena, below Jakutsk, in north lat. 64.

2. Rhinoceros bicornis, the two-horned

rhinoceros, is found in various parts of Africa, and seems to have been the kind which was known to the antient Romans, and by them exhibited in their public shows and combats of animals. In size it equals the common or single-horned species; and its habits and manner of feeding are the same; but it differs greatly in the appearance of its skin, which, instead of the vast and regularly marked armour-like folds of the former, has merely a very slight wrinkle across the shoulders, and on the hinder parts with a few fainter wrinkles on the sides, so that, in comparison with the common rhinoceros, it appears almost smooth; the skin, however, is rough or tuberculated, especially in the larger specimens; but what constitutes the specific or principal distinction is, that the nose is furnished with two horns, one of which is smaller than the other, and situated above it, or higher up on the front. These horns are said to be loose when the animal is in a quiet state, but to become firm and immoveable when it is enraged. This observation is confirmed by Dr. Sparman, who observed, in a specimen which he shot in Africa, that they were fixed to the nose by a strong apparatus of muscles and tendons, so as to allow the animal the power of giving them a steady fixture on proper occasions. This, indeed, is treated by Mr. Bruce, the celebrated Abyssinian traveller, as an absurd idea; but, on inspecting the horns and skin on which they are seated, it does not appear that they are firmly attached to, or connected with, the bone of the cranium. See Plate Nat. Hist. fig. 347.

Mr. Bruce's description of the manner of feeding, as well as of some other particulars relative to the two-horned rhinoceros, seems highly worthy of notice. He informs us, that, "besides the trees capable of most resistance, there are, in the vast forests within the rains, trees of a softer consistence, and of a very succulent quality, which seem to be destined for his principal food. For the purpose of gaining the highest branches of these, his upper lip is capable of being lengthened out so as to increase his power of laying hold with this in the same manner as the elephant does with his trunk. With this lip, and the assistance of his tongue, he pulls down the upper branches which have most leaves, and these he devours first; having stripped the tree of its branches, he does not, therefore, abandon it; but, placing his snout as low in the trunk as he finds his horns will enter, he rips up the body of the tree, and reduces it to thin pieces like so many laths; and when he has thus prepared it, he embraces as much of it as he can in his monstrous jaws, and twists it round with as much ease as an ox would do a root of celery, or any such pot-herb or garden-stuff.

"When pursued, and in fear, he possesses an astonishing degree of swiftness, considering his size, the apparent unwieldiness of his body, his great weight before, and the shortness of his legs. He is long, and has a kind of trot, which, after a few minutes, increases in a great proportion, and takes in a great distance; but this is to be understood with a degree of moderation. It is not true, that in a plain he beats the horse in swiftness. I have passed him with ease, and seen many worse mounted do the same, and though it is certainly true that a horse can very seldom come up with him, this is owing to his cunning but not his swiftness.

"The eyes of the rhinoceros are very small, and he seldom turns his head, and therefore sees nothing but what is before him. To this he owes his death, and never escapes if there is so much plain as to enable the horse to get before him. His pride and fury, then, make him lay aside all thoughts of escaping, but by victory over his enemy. He stands for a moment at bay, then, at a start, runs straight forward at the horse like the wild boar, whom, in his manner of action, he very much resembles. The horse easily avoids him by turning short aside; and this is the fatal instant: the naked man, with the sword, drops from behind the principal horseman, and, unseen by the rhinoceros, who is seeking his enemy, the horse, he gives him a stroke across the tendon of the heel, which renders him incapable of further flight or resistance.

"In speaking of the great quantity of food necessary to support this enormous mass, we must likewise consider the vast quantity of water which he needs. No country but that of the Shangalla, which he possesses, deluged with six months' rain, and full of large and deep basons, made in the living rock, and shaded by dark woods from evaporation, or watered by large and deep rivers, which never fall low or to a state of dryness, can supply the vast draughts of this monstrous creature. But it is not for drinking alone that he frequents wet and marshy places: large, fierce, and strong, as he is, he must submit to prepare himself against the weakest of all adversaries. The great consumption he constantly makes of food and water necessarily confine him to certain limited spaces; for it is not every place that can maintain him; he cannot emigrate, or seek his defence among the sands of Atbara."

The adversary just mentioned is a fly (probably of the genus œstrus), which attacks the rhinoceros, as well as the camel and many other animals, and would, according to Mr. Bruce, as easily subdue him, but for the stratagem which he practises of rolling himself in the mud by night, by which means he clothes himself in a kind of case, which defends him from his adversary the following day. The pleasure that he receives from thus rolling in the mud, and the darkness of the night, deprive him of his usual vigilance and attention. The hunters steal secretly upon him, and while lying on the ground wound him with their javelins, mostly in the belly, where the wound is mortal.

RHINOMACER, a genus of insects of the order coleoptera. The generic character is, antennæ setaceous, seated on the snout; feelers four, growing thicker towards the end, the last joint truncate. There are three species: the curculioides, that inhabits Italy; the attelaboides, that inhabits Sweden; and the cæruleus, found in Calabria.

RHIZOBALUS, a genus of the tetragynia order, in the polyandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is monophyllous, fleshy, and downy; the corolla consists of five petals, which are round, concave, fleshy, and much larger than the calyx; the stamina are very numerous, filiform, and longer than the corolla; the styli are four, filiform, and of the length of the stamina; the pericarpium has four drupæ, kidney-shaped, compressed, with a fleshy substance inside, and in the middle a flat large nut, containing a kidney-shaped kernel. Of this there are two species: the most remarkable is the pekia. The nut is sold in the shops as American nuts: they are flat, tuberculated, and kidney-shaped, containing a kernel of the same shape, which is sweet and agreeable.

RHIZOPHORA, the *mangrove* or *mangle*, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is quadripartite, the corolla four-parted; there is one seed, very long, and carnous at the base. There are six species.

These plants are natives of the East and West Indies, and often grow 40 or 50 feet high. They grow only in water and on the banks of rivers, where the tide flows up twice a day. They preserve the verdure of their leaves throughout the year. From the lowest branches issue long roots, which hang down to the water, and penetrate into the earth. In this position they resemble so many arcades, from five to ten feet high, which serve to support the body of the tree, and even to advance it daily into the bed of the water. These arcades are so closely intertwisted one with another, that they form a kind of natural and transparent terrace, raised with such solidity over the water, that one might walk upon them, was it not that the branches are too much incumbered with leaves. The most natural way of propagating these trees is to suffer the several slender small filaments which issue from the main branches to take root in the earth. The most common method, however, is that of laying the small lower branches in baskets of mould or earth till they have taken root.

The description just given pertains chiefly to a particular species of mangrove, R. mangle, termed by the West Indians black mangles, on account of the brown dusky colour of the wood. The bark is very brown, smooth, pliant when green, and generally used in the West India islands for tanning of leather. Below this bark lies a cuticle or skin, which is lighter, thinner, and more tender. The wood is nearly of the same colour as the bark; hard, pliant, and very heavy. It is frequently used for fuel; the fires which are made of this wood being both clearer, more ardent and durable, than those made of any other materials whatever. The wood is almost incorruptible, never splinters, is easily worked, and was it not for its enormous weight, would be commodiously employed in almost all kinds of work, as it possesses every property of good timber. To the roots and branches of mangroves that are immersed in the water, oysters frequently attach themselves; so that wherever this curious plant is found growing on the sea-shore, oyster-fishing is very easy; as in such cases these shell-fish may be literally said to be gathered upon trees.

The red mangle or mangrove, a variety of the above, grows on the sea-shore, and at the mouth of large rivers; but does not advance, like the former, into the water. It generally rises to the height of 20 or 30 feet, with crooked knotty branches, which proceed from all parts of the trunk. The bark is slender, of a brown colour, and, when young, is smooth, and adheres very closely to the wood; but when old, appears quite cracked, and is easily detached from it. Under this bark is a skin as thick as parchment, red, and adhering closely to the wood, from which it cannot be detached till the tree is felled and dry. The wood is hard, compact, heavy, of a deep red, with a very fine grain. The pith or heart of the wood being cut into small pieces, and boiled in water, imparts a very beautiful red to the liquid, which communicates the same colour to wool and linen. The great weight and hardness of the wood prevent it from being generally used. From the fruit of this tree, which, when ripe, is of a violet-colour, and resembles some grapes in taste, is prepared an agreeable liquor, much esteemed by the inhabitants of the Caribbee islands.

White mangle; another variety, so termed from the colour of its wood, grows, like the two former, upon the banks of rivers, but is seldom found near the sea. The bark is grey; the wood, as we have said, white, and when green, supple; but dries as soon as cut down, and becomes very light and brittle. This species is generally called rope-mangrove, from the use to which the bark is applied by the inhabitants of the West Indies. This bark, which, from the great abundance of sap, is easily detached when green from the wood, is beaten or bruised betwixt two stones, until the hard and woody part is totally separated from that which is soft and tender. This last, which is the true cortical substance, is twisted into ropes of all sizes, which are exceedingly strong, and not apt to rot in the water.

RHODIOLA, *rose-wort*, a genus of the octandria order, in the diœcia class of plants, and in the natural method ranking under the 13th order, succulentæ. The male calyx is quadripartite, the corolla tetrapetalous. The female calyx is quadripartite, and there is no corolla; the nectaria are four; the pistils four; and there are four polyspermous capsules. There are two species, the rosea and the biternata; the first grows naturally in the clefts of the rocks and rugged mountains of Wales, Yorkshire, and Westmorland. It has a very thick fleshy root, which when cut or bruised sends out an odour like roses. It has thick succulent stalks, like those of orpine, about nine inches long, with thick succulent leaves indented at the top. The stalk is terminated by a cluster of yellowish herbaceous flowers, which have an agreeable scent, but are of short continuance. The second sort is a native of Cochin China. Both species are easily propagated by parting their roots, and require a shady situation and dry undunged soil. The fragrance of the first species, however, is greatly diminished by cultivation.

RHODODENDRUM, *dwarf rose-bay*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 18th order, bicornes. The calyx is quinquepartite; the corolla funnel-shaped; the stamina declining; the capsule quinquelocular. There are nine species; the most remarkable of which are,

1. The hirsutum, with naked hairy leaves, grows naturally on the Alps and several mountains of Italy. It is a low shrub, which seldom rises two feet high, sending out many ligneous branches covered with a light-brown bark, and oval spear-shaped leaves, sitting pretty close to the branches. They are entire, having a great number of fine iron-coloured hairs on their edges and underside. The flowers are produced in bunches at the end of the branches in May, having one funnel-shaped petal cut into five obtuse segments, and of a pale-red colour.

2. The ferrugineum, with smooth leaves, hairy on their under side, is a native of the Alps and Apennines. It rises with a shrubby stalk near three feet high, sending out many irregular branches covered with a purplish bark, and smooth spear-shaped entire leaves, whose borders are reflexed backward; the upper side is of a light lucid green, their under side of an iron-colour. The flowers are produced at the ends of the branches, are funnel-shaped, cut into five segments, and of a pale rose-colour. These plants are propagated by seeds; but being natives of barren rocky soils and cold situations, they do not thrive in gardens, and for want of their usual covering of snow in the winter, are often killed by frost in this country.

3. The chamæcistus, or ciliated-leaved dwarf rose-bay, is a low deciduous shrub, native of mount Baldus, and near Saltzburg, in Germany. It grows to the height of about a yard; the branches are numerous, produced irregularly, and covered with a purplish bark. The leaves are oval, spear-shaped, small, and in the under surface of the colour of iron. The flowers are produced at the end of the branches in bunches, are of a wheel-shaped figure, pretty large, of a fine crimson colour, and handsome appearance. They appear in June.

4. The dauricum, or Daurian dwarf rose-bay, is a low deciduous shrub, and native of Dauria. Its branches are numerous, and covered with a brownish bark. The flowers are wheel-shaped, large, and of a beautiful rose-colour: they appear in May, and are succeeded by oval capsules full of seeds, which in England do not always ripen.

5. The maximum, or American mountain laurel, is an evergreen shrub, and native of Virginia, where it grows naturally on the highest mountains, and on the edges of cliffs, precipices, &c. where it reaches the size of a moderate tree, though with us it seldom rises higher than six feet. The flowers continue by succession sometimes more than two months, and are succeeded by oval capsules full of seeds.

6. The ponticum, or pontic dwarf rose-bay, is an evergreen shrub, native of the East, and of most shady places near Gibraltar. It grows to the height of four or five feet. The leaves are spear-shaped, glossy on both sides, acute, and placed on short foot-stalks on the branches: the flowers, which are produced in clusters, are bell-shaped, and of a fine purple colour. They appear in July, and are succeeded by oval capsules containing seeds, which in England seldom attain to maturity.

In Siberia, a species of this plant is used with great success in gouty and rheumatic affections; and the inhabitants of Siberia call this shrub chei or tea, from their drinking in common a weak infusion of it, as we do the Chinese plant of that name. This practice shows that the plant, used in small quantities, must be innocent.

RHODORA, a genus of the decandria monogynia class and order. The calyx is five-toothed; petals three, unequal; stamina declined; capsules five-celled. There is one species, a shrub of Newfoundland.

RHOPALA, or RUPALA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking with those that are doubtful. There is no calyx; the petals are four, oblong, obtuse, and narrowing at the base; the stamina are four, inserted in the corolla, and have large antheræ; the seed-vessel unilocular, and contains one seed. There are only two species. The montana is a shrubby plant growing in Guiana, and remarkable for the great number of branches sent off from its trunk in every direction, and for the fetid smell of the wood and bark of this plant. The other is a native of Cayenne.

RHOMBOIDES. See GEOMETRY.

RHOMBUS. See GEOMETRY.

RHUBARB. See RHEUM, and PHARMACY.

RHUMB, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense rhumb is the same with a point of the compass.

RHUMB-LINE, is also used for the line which a ship describes when sailing in the same collateral point of the compass, or oblique to the meridians. See NAVIGATION.

RHUS, *sumach*, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quinquepartite; the petals five; the berry monospermous. There are 34 species, of which the most remarkable are,

1. The coriaria, or elm-leaved sumach, grows naturally in Italy, Spain, Turkey, Syria, and Palestine. The branches of this tree are used instead of oak-bark for tanning of leather; and it is said that the Turkey leather is all tanned with this shrub. It has a ligneous stalk, which divides at bottom into many irregular branches, rising to the height of eight or ten feet; the bark is hairy, of a herbaceous brown colour; the leaves are winged, composed of seven or eight pair of lobes, terminated by an odd one, bluntly sawed on their edges, hairy on their under side, of a yellowish-green colour, and placed alternately on the branches; the flowers grow in loose panicles on the end of the branches, which are of a whitish herbaceous colour, each panicle being composed of several spikes of flowers sitting close to the footstalks. The leaves and seeds of this sort are used in medicine, and are esteemed very restringent and styptic.

2. The typhinum, Virginian sumach, or vinegar-plant, grows naturally in almost every part of North America. This has a woody stem, with many irregular branches, which are generally crooked and deformed. The young branches are covered with a soft velvet-like down, resembling greatly that of a young stag's horn, both in colour and texture, whence the common people have given it the appellation of stag's horn; the leaves are winged, composed of six or seven pair of ob-

long heart-shaped lobes. The flowers are produced in close tufts at the end of the branches, and are succeeded by seeds, inclosed in purple woolly succulent covers; so that the bunches are of a beautiful purple colour in autumn; and the leaves, before they fall in autumn, change to a purplish colour at first, and before they fall to a feuillemort. It has got the name of the vinegar-plant from the double reason of the young germen of its fruit, when fermented, producing either new or adding to the strength of old weak vinegar, whilst its ripe berries afford an agreeable acid, which might supply the place when necessary of the citric acid. The powerful astringency of this plant in all its parts recommends it as useful in several of the arts. As for example, the ripe berries boiled with alum make a good dye for hats. The plant in all its parts may be used as a succedaneum for oak-bark in tanning, especially the white glove-leather. It will likewise answer to prepare a dye for black, green, and yellow colours; and with martial vitriol it makes a good ink. The milky juice that flows from incisions made in the trunk or branches, makes, when dried, the basis of a varnish little inferior to the Chinese. Bees are remarkably fond of its flowers; and it affords more honey than any of the flowering shrubs. The natives of America use the dried leaves as tobacco.

3. The glabrum, with winged leaves, grows naturally in many parts of North America: this is commonly called by the gardeners New England sumach. The stem of this is stronger and rises higher than that of the former; the branches spread more horizontally; the flowers are disposed in loose panicles, which are of an herbaceous colour.

4. The elegans, with sawed winged leaves, grows naturally in Carolina: the seeds of this were brought thence by the late Mr. Catesby. This is by the gardeners called the scarlet Carolina sumach: it rises commonly to the height of seven or eight feet, dividing into many irregular branches, which are smooth, of a purple colour, and pounced over with a greyish powder, as are also the footstalks of the leaves. The leaves are composed of seven or eight pair of lobes terminated by an odd one. The upper sides of the lobes are of a dark green, and their under hoary but smooth. The flowers are produced at the end of the branches in very close panicles, which are large, and of a bright-red colour.

5. The copallinum, or narrow-leaved sumach, grows naturally in most parts of North America, where it is known by the title of beach sumach, probably from the place where it grows. This is of humbler growth than either of the former, seldom rising more than four or five feet high in Britain, dividing into many spreading branches, which are smooth, of a light brown colour, with winged leaves, composed of four or five pair of narrow lobes, terminated by an odd one; they are of a light green on both sides. The flowers are produced in loose panicles at the end of the branches, of a yellowish herbaceous colour.

These are hardy plants, and will thrive in the open air here. The first and fourth sorts are not quite so hardy as the others, so must have a better situation, otherwise their branches will be injured by severe frost in the winter.

6. Besides these, Linnæus has included in this genus the toxicodendron, or poison-tree, under the name of rhus vernix, or poison-ash. This grows naturally in Virginia, Pennsylvania, New England, Carolina, and Japan, rising with a strong woody stalk to the height of twenty feet and upwards; though in this country it is seldom seen above twelve, by reason of the plant's being extremely tender. The bark is brown, inclining to grey; the leaves winged, and composed of three or four pair of lobes, terminated by an odd one. The lobes vary greatly in their shape, but for the most part they are oval and spear-shaped. The footstalks become of a bright purple towards the latter part of summer, and in autumn all the leaves are of a beautiful purple before they fall off.

All the species of sumach abound with an acrid milky juice, which is reckoned poisonous; but this property is most remarkable in the vernix.

The natives are said to distinguish this tree in the dark by its extreme coldness to the touch. The juice of some kinds of sumach, when exposed to the heat of the sun, becomes so thick and clammy, that it is used for bird-lime, and the inspissated juice of the poison-ash is said to be the fine varnish of Japan. A cataplasm made with the fresh juice of the poison-ash, applied to the feet, is said by Hughes, in his Natural History of Barbadoes, to kill the vermin called by the West Indians chigers. The resin called gum copal is from the rhus copallinum. See Copal.

RHYME. See Poetry.

RHYTHMICAL, in music, an epithet applied to the property or quality, in the antient melopœia and modern melody, by which the cadences, accents, and quantities, are regulated and determined.

RIAL, or Ryal. See Coin.

Rial, or Royal, is also the name of a piece of gold, antiently current among us for ten shillings.

RIBBAND, or Ribbon, a narrow sort of silk, chiefly used for head-ornaments, badges of chivalry, &c.

RIBES, the *currant* and *gooseberry-bush*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 36th order, pomaceæ. There are five petals, and stamina inserted into the calyx; the style is bifid; the berry polyspermous, inferior. The currant and the gooseberry were long considered each as a separate genus; ribes the currant, and grossularia the gooseberry; but they are now joined together, the grossularia being made a species of ribes; all the currant kinds having inermous or thornless branches, and racemous clusters of flowers and fruit; and the gooseberry having spinous branches, and flowers and fruit for the most part singly.

There are ten species of the currant-tree, two of which, and their varieties, merit culture for their fruit: all are inermous or unarmed, having no thorns on the branches.

1. The rubrum, grows naturally in woods and the hedges in most parts of Europe, and comprises all sorts of red and white currants; as common small red currant, large-bunched red currant, Champaigne pale-red currant, common small white currant, large white Dutch currant, yellow blotched-leaved currant, silver-striped-leaved, gold-striped-leaved, gooseberry-leaved. All these sorts are varieties of one species, ribes rubrum, or common red currant; it being the parent from which all the others were first obtained from the seed, and improved by culture.

2. The nigrum, or black-currant tree. The fruit of this species being of a strong flavour, and somewhat physical relish, is not generally liked: it, however, is accounted very wholesome. There is also made of it a syrup of high estimation for sore throats and quinsies. There is a variety called the Pennsylvanian black currant, having smaller shoots, and leaves not strong-scented, and small fruit but of little value.

Of the gooseberry, there are seven species. The most remarkable are,

1. The grossularia, or rough hairy gooseberry bush. It consists of many varieties, of different sizes and colours.

2. The reclinatum, or reclinated broad-leaved gooseberry bush.

3. The oxyacanthoides, or oxyacantha-leaved gooseberry, with largish trilobate hawthorn leaves.

4. The uva crispa, or smooth gooseberry.

5. The cynosbati, or prickly-fruited gooseberry-bush, has a shrubby stem and branches, armed with spines, mostly at the axillas, and prickly fruit in clusters.

RIBS. See Anatomy.

RICCIA, a genus of the natural order of algæ, belonging to the cryptogamia class of plants. There is no calyx, but a vesicular cavity within the substance of the leaf. There is no corolla; the antheræ are cylindrical and sessile, placed on the germen, which is turbinated; the stile is filiform, perforating the anthera; and the seed-case is spherical, crowned with the withered antheræ; the seeds are hemispherical and pedicellated. There are five species.

RICHARDIA, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The calyx is sexpartite; the corolla monopetalous and subcylindrical; and there are three seeds. There is one species, a herb of Vera Cruz.

RICHERIA, a genus of the class and order diœcia pentandria. The capsule is cortical, six-valved, three-celled; seeds solitary; stile trifid. There is one species, a tree of the West Indies.

RICINUS, or Palma Christi, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The male calyx is quinquepartite; there is no corolla; the stamina numerous. The female calyx is tripartite; there is no corolla, but three bifid styles, with a trilocular capsule, and a single seed. There are six species, of which the most remarkable is the communis, or common palma Christi. This tree is of speedy growth, as in one year it arrives at its full height, which seldom exceeds twenty feet. The trunk is subligneous; the pith is large; the leaves broad and palmated; the flower-spike is simple, and thickly set with yellow blossoms in the shape of a cone; the capsules are triangular and prickly, containing three smooth grey mottled seeds. When the bunches begin to turn black, they are gathered, dried in the sun, and the seeds picked out. They are afterwards put up for use as wanted, or for exportation.

Castor oil is obtained either by expression or by decoction. The first method is practised in England; the latter in Jamaica. It is common first to parch the nuts or seeds in an iron pot over the fire; but this gives the oil an empyreumatic taste, smell, and colour; and it is best prepared in the following manner: A large iron pot or boiler is first prepared, and half-filled with water. The nuts are then beaten in parcels in deep wooden mortars, and after a quantity is beaten, it is thrown into the iron vessel. The fire is then lighted, and the liquor is gently boiled for two hours, and kept constantly stirred. About this time the oil begins to separate, and swims on the top, mixed with a white froth, and is skimmed off till no more rises. The skimmings are heated in a small iron pot, and strained through a cloth. When cold, it is put up in jars or bottles for use.

Castor oil, thus made, is clear and well flavoured, and if put into proper bottles will keep sweet for years. The expressed castor oil soon turns rancid, because the mucilaginous and acrid parts of the nut are squeezed out with the oil. On this account the preference is given to well-prepared oil by decoction. An English gallon of the seeds yield about two pounds of oil, which is a great proportion.

Before the disturbances in America, the planters imported train oil for lamps and other purposes about sugar-works. It is now found that the castor oil can be procured as cheap as the fish oil of America. It burns clearer, and has not any offensive smell. This oil, too, is fit for all the purposes of the painter, or for the apothecary in ointments and plasters. As a medicine, it purges without stimulus, and is so mild as to be given to infants soon after birth. All oils are noxious to insects, but the castor oil kills and expels them. It is generally given as a purge after using the cabbage-bark some days.

The ricinus Americanus grows as tall as a little tree, and is so beautiful that Miller says it deserves a place in every curious garden, and he planted it himself at Chelsea. It expands into many branches; the leaves are sometimes two feet in diameter, and the stem as large as a middle-sized broom-staff: towards the top of the branch it has a cluster of flowers, somewhat resembling a bunch of grapes; the flowers are small and staminous, but on the body of the plant grow bunches of rough triangular husks, each containing three speckled seeds, generally somewhat less than horse-beans; the shell is brittle, and contains white kernels of a sweet, oily, and nauseous taste. From this kernel the oil is extracted; and if the medicine should become officinal, the seeds may be imported at a reasonable rate, as the plant grows wild and in great plenty in all the British and French American islands.

Of the ricinus communis, there are a great many varieties; all of them fine majestic plants, annual, or at most biennial, in this country; but in their native soil they are said to be perennial both in root and stem. They are propagated by seeds sown on a hotbed, and require the same treatment as other tender exotics.

RICKETS. See INFANCY.

RICOTIA, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The siliqua is unilocular, oblong, and compressed, with plain valvules. There is one species.

RIDE, in the sea language, is a term variously applied: thus, a ship is said to ride, when her anchors hold her fast, so that she does not drive by the force either of the wind or tide. A ship is said to ride across, when she rides with her fore and main yards hoisted up to the hounds, and both yards and arms topped alike. She is said to ride well, when she is built so as not to overbeat herself in a head-sea, the waves over raking her from stem to stern. To ride athwart, is to ride with her side to the tide. To ride betwixt wind and tide, is to ride so that the wind has equal force over her one way, and the tide the contrary way. If the wind has more power over the ship than the tide, she is said to ride wind-road, or to ride a great wind.

RIDEAU, in fortification, is a small elevation of earth, extending lengthwise on a plain, and serving to cover a camp, or to give an advantage to a post. Rideaus are also convenient for those who would besiege a place, and serve to secure the workmen in their approaches to the foot of a fortress.

RIDERS, in a ship, are large timbers, both in the hold and aloft, bolted on to other timbers to strengthen them, when the ship is discovered to be too slightly built.

RIDING-CLERK, one of the six clerks in chancery, who, in his turn, annually keeps the controlment-books of all grants that pass the great seal that year.

RIENS ARREAR, in law, is a plea used in an action of debt, for arrearages of accounts, by which the defendant alleges, that there is nothing in arrear.

RIFLE, a fire-arm which has the inside of its barrel cut with from three to nine or ten spiral grooves, so as to make it resemble a female screw, varying from a common screw only in this, that its grooves or rifles are less deflected, and approach more to a right line; it being now usual for the grooves with which the best rifled barrels are cut, to take about one whole turn in a length of thirty inches. The number of these grooves differs according to the size of the barrel and fancy of the workman; and their depth and width are not regulated by any invariable rule.

Rifles are said to have been known as far back as the middle of the sixteenth century. See Plate Rifle, &c. fig. 1, which represents a cast taken of the inside of a rifle-barrel thirty inches long and $\frac{6}{10}$ of an inch in diameter, and in which the grooves take one turn in the whole length. It will of course be observed, that the ribs in the drawing represent the grooves in the rifle. The method of loading them is as follows:

When the proper quantity of powder (one drachm avoirdupois) is put down at the muzzle, and a piece of calico or linen is gently rammed down over it as a wad, a circular piece of strong calico is greased on one side, and laid on the mouth of the piece with the greased side downwards; and a bullet of the same size as the bore of the piece before the grooves were cut, being placed upon it, is then forced gently down the barrel with it; by which means, the calico incloses the lower half of the bullet: and by its interposition between the bullet and the grooves, prevents the lead from being cut by them, and by means of the grease slides down, without its being necessary to use any violent efforts, which would destroy the circular shape of the bullet.

In order to understand the cause of the superiority of a rifle-barrel gun over one with a smooth barrel, it will be necessary to refer to Mr. Robins's discovery of the cause of the irregularities which occur in the flight of projectiles from smooth barrels, which we shall give in his own words, Tracts on Gunnery, p. 196, &c.

"Almost every projectile, besides the forces we have hitherto considered, namely, its gravitation, and that resistance of the air which directly opposes its motion, is affected by a third force which acts obliquely to its motion, and in a variable direction; and which consequently deflects the projectile from its regular track, and from the vertical plane in which it began to move; impelling it sometimes to one side, and sometimes to the other, occasioning thereby very great inequalities in the repeated ranges of the same piece, though each time loaded and pointed in the same manner; and this force operating thus irregularly, I conceive to be the principal source of all that uncertainty and confusion in the art of gunnery, which hath hitherto been usually ascribed to the difference of powder. The reality of this force, and the cause which produces it, will, I hope, appear from the following considerations.

"It will easily be granted, I suppose, that no bullet can be discharged from the pieces generally in use, without rubbing against their sides, and thereby acquiring a whirling motion as well as a progressive one. And as this whirl will, in one part of its revolution, conspire in some degree with the progressive motion, and in another part be equally opposed to it, the resistance of the air on the fore part of the bullet will be hereby affected, and will be increased in that part where the whirling motion conspires with the progressive, and diminished where it is opposed to it. And by this means the whole effort of the resistance, instead of being in a direction opposite to the direction of the body, will become oblique thereto, and will produce those effects already mentioned. If it were possible to predict the position of the axis round which the bullet should whirl, and if that axis were unchangeable during the whole flight of the bullet, then the aberration of the bullet by this oblique force would be in a given direction, and the incurvation produced thereby would regularly extend the same way, from one end of its track to the other. For instance: if the axis of the whirl were perpendicular to the horizon, then the deflection would be to the right or left; if that axis were horizontal, and perpendicular to the direction of the bullet, then the deflection would be upwards or downwards. But as the first position of this axis is uncertain, and as it may perpetually shift in the course of the bullet's flight, the deviation of the bullet is not necessarily in one certain direction, nor tending to the same side in one part of its track that it does in another; but it more usually is continually changing the tendency of its deflection, as the axis, round which it whirls, must frequently shift its position to the progressive motion by many inevitable accidents."

To prove the truth of his theory, Mr. Robins made the following experiments, before several members of the Royal Society:

"The first experiment, exhibited on this occasion, was to evince, that the whirling motion of a ball, combining with its progressive motion, would produce such an oblique resistance and deflective power, as is herein mentioned. For this purpose, a wooden ball, 4½ inches diameter, was suspended by a double string about eight or nine feet long. Now by turning round the ball, and twisting the double string, the ball, when left to itself, would have a revolving motion given it from the untwisting of the string again. And if, when the string was twisted, the ball was drawn a considerable distance from the perpendicular, and there let go; it would at first, before it had acquired its revolving motion, vibrate steadily enough in the same vertical plane in which it first began to move; but when, by the untwisting of the string, it had acquired a sufficient degree of its whirling motion, it constantly deflected on the right or left of its first track, and sometimes proceeded so far, as to have its direction at right angles to that in which it began its motion; and this deviation was not produced by the action of the string itself, but appeared to be entirely owing to the resistance being greater on the one part of the leading surface of the globe than on the other. For the deviation continued when the string was totally untwisted, and even during the time that the string, by the motion the globe had received, was twisting the contrary way. And it was always easy to predict, before the ball was let go, which way it would deflect, only by considering on which side the whirl would be combined with the progressive motion, for on that side always the deflecting power acted; as the resistance was greater here, than on the side where the whirl and progressive motion were opposed to each other.

"This experiment is an incontestable proof, that, if any bullet, besides its progressive motion, hath a whirl round its axis, it will be deflected in the manner here described. And as it is scarcely possible to suppose, but that every bullet, discharged from the pieces now in common use, must receive such a whirl from its friction against the sides of the piece, the proposition might perhaps be safely rested on this single experiment. But not to leave any thing doubtful in a subject liable to so much contestation, I undertook to evince, by an ocular proof, the reality of this deflection in musquet-bullets even in so short an interval as a hundred yards. And these experiments having succeeded to the general satisfaction of those who honoured me with their company, I shall here describe, as briefly as I can, the manner in which they were tried, and the conclusions resulting from them.

"As all projectiles in their flight are acted on by the power of gravity, the deflection of a bullet from its primary direction, supposes that deflection to be upwards or downwards in a vertical plane; because, in the vertical plane, the action of gravity is compounded and entangled with the deflective force. And for this reason, my experiments have been principally directed to the examination of that deflection, which carries the bullet to the right or left of the vertical plane, in which it began to move. For if it appears at any time, that the bullet has shifted from that vertical plane, in which its motion began, this will be an incontestable confirmation of what we asserted. Since no other power but that unequal resistance, which we here insist on, can occasion a body in motion to deviate from the vertical plane, in which it has once moved.

"Now by means of screens of exceedingly thin paper, placed parallel to each other at proper distances, this deflection in question may be many ways investigated. For by firing bullets which shall traverse these screens, the flight of the bullet may be traced out; and it may easily appear, whether they do or do not keep invariably to one vertical plane. This examination may proceed on three different principles, which I shall here separately explain.

"For first, an exact vertical plane may be traced out upon all these screens, by which the deviation of any single bullet may be more readily investigated; only by measuring the horizontal distance of its trace from the vertical plane thus delineated, and by this means the absolute quantity of its aberration may be known.

"Or if the description of such a vertical plane should be esteemed a matter of difficulty and nicety, a second method may be followed; which is that of resting the piece in some fixed notch or socket, so that though the piece may have some little play to the right and left, yet all the lines, in which the bullet can be directed, shall intersect each other in the centre of that fixed socket; by this means, if two different shot are fired from the piece thus situated, the horizontal distances of the traces made by the two bullets on any two screens, ought to be in the same proportion to each other as the respective distances of these screens from the socket, in which the piece was laid. And if these horizontal distances differ from that proportion, then it is certain, that one of these shot at least hath deviated from a vertical plane, although the absolute quantity of that deviation cannot be hence assigned; because it cannot be known, what part of it is to be imputed to one bullet, and what to the other.

"But if the constant and invariable position of the notch or socket, in which the piece was placed, is thought too hard an hypothesis in this very nice affair; the third method, and which is the simplest of all, requires no more than, that two shot be fired through three screens, without any regard to the position of the piece each time. For, in this case, if the shots diverge from each other, and both keep to a vertical plane, then if the horizontal distances of their traces on the first screen be taken from the like horizontal distances on the second and third, the two remainders will be in the same proportion with the distances of the second and third screen from the first. And if they are not in this proportion, then it will be certain, that one of them at least hath been deflected from the vertical plane; though here, as in the last instance, the quantity of that deflection in each will not be known.

"All these three methods I have myself made use of at different times, and have ever found the success agreeable to my expectation. But what I thought the most eligible for the experiments, which I proposed to shew to the society, was a compound of the two last, and the apparatus was as follows:

"On ——, being the first day appointed for these trials, the weather was unfavourable, and the experiments on that account more confused than could have been wished, though they were far from inconclusive. But on the next Thursday two screens were set up in the large walk in the Charter-house garden; the first of them at 250 feet distance from the wall (which wall was to serve for a third screen), and the second two hundred feet from the same wall. And at fifty feet before the first screen, or at 300 feet from the wall, there was placed a large block, weighing about 200lb. weight, and having fixed into it an iron bar with the socket at its extremity, in which the piece was to be laid. The piece itself was of a common length, and was bored for an ounce ball. It was each time loaded with a ball of 17 to the pound (so that the windage was extremely small) and with a quarter of an ounce of good powder. The screens were made of the thinnest tissue-paper; and the resistance they gave to the bullet (and consequently their probability of deflecting it) was so small, that a bullet lighting one time near the extremity of one of the screens, left a fine thin fragment of it towards the edge entire, which was so very weak, that it appeared difficult to handle it without breaking. These things thus prepared, five shot were made with the piece rested in the notch described above; and the horizontal distances between the first shot, which was taken as a standard, and the four succeeding ones, both on the first and second screen, and on the wall, measured in inches, were as follows:

	1st screen	2d screen	wall
1 to 2	1,75 R	3,15 R	16,7 R
3	10, L	15,6 L	69,25 L
4	1,25 L	4,5 L	15,0 L
5	2,15 L	5,1 L	19,0 L

"Here the letters R and L denote, that the shot in question went either to the right or left of the first.

"If the position of the socket in which the piece was placed, be supposed fixed (and I presume no person then present conceived, during these trials, that it could possibly vary the tenth of an inch from its first situation), then the horizontal distances, measured above on the first and second screen, and on the wall, ought to be in the proportion of the distances of the 1st screen, the 2d screen, and the wall, from the socket. But, by only looking over these numbers, it appears, that none of them are in that proportion; the horizontal distance of the 1st and 3d (for instance) on the wall being above nine inches more than it should be by this analogy.

"If without supposing the invariable position of the socket, we examine the comparative horizontal distances according to the third method described above, we shall in this case discover divarications still more extraordinary. For by the numbers set down it appears, that the horizontal distances of the 2d and 3d shot on the two screens, and on the wall, are as under:

1st screen	2d screen	wall
11,75	18,75	85,95

"Here, if, according to the rule given above, the distance on the first screen be taken from the distances on the other two, the remainder will be 7, and 74,2; and these numbers, if each shot kept to a vertical plane, ought to be in the proportion of 1 to 5, that being the proportion of the distances of the second screen and of the wall from the first. But the last number 74,2 exceeds what it ought to be by this analogy, by 39,2; so that between them there is a deviation from the vertical plane of above 39 inches, and this too in a transit of little more than eighty yards.

"But further, to shew that these irregularities do not depend upon any accidental circumstances of the ball's fitting or not fitting the piece, there were five shot more made with the same quantity of powder as before; but with smaller bullets, which ran much looser in the piece. And the horizontal distances being measured in inches from the trace of the first bullet to each of the succeeding ones, the numbers were as follow:

	1st screen	2d screen	wall
1 to 2	15,6 R	31,1 R	94,0 R
3	6,4 L	12,75 L	23,0 L
4	4,7 R	8,5 R	15,5 R
5	12,6 R	24,0 R	63,5 R

"Here again, on the supposed fixed position of the piece, the horizontal distance on the wall, between the first and third, will be found to be above fifteen inches less than it should be, if each kept to a vertical plane. And like irregularities, though smaller, occur in every other experiment. And if they are examined according to the third method set down above, and the horizontal distances of the third and fourth, for instance, are compared, these on the first and second screen, and on the wall, appear to be thus:

1st screen	2d screen	wall
11,1	21,25	38,5

"And if the horizontal distance on the first screen is taken from the other two, the remainders will be 10,15 and 27,4; where the last of them, instead of being five times the first, as it ought to be, is 23,35 short of it. So that here there is a deviation of above 23 inches.

"From all these experiments the deflection in question seems to be incontestably evinced. But to give some farther light to this subject, I took a barrel of the same bore with that hitherto used, and bent it at about three or four inches from its muzzle to the left, the bend making an angle of 3° or 4° with the axis of the piece. This piece, thus bent, was fired with a loose ball and the same quantity of powder hitherto used, the screens of the last experiment being still continued. It was natural to expect that if this piece was pointed by the general direction of its axis, the ball would be canted to the left of that direction by the bend near its mouth. But as the bullet, in passing through that bent part, would, as I conceived, be forced to roll upon the right-hand side of the barrel; and thereby the left side of the bullet would turn up against the air, and would increase the resistance on that side; I predicted to the company then present, that if the axis on which the bullet whirled did not shift its position after it was separated from the piece, then, notwithstanding the bend of the piece to the left, the bullet itself might be expected to incurvate towards the right; and this, upon trial, did most remarkably happen. For one of the bullets fired from this bent piece, passed through the first screen about 1½ inch distant from the trace of one of the shot fired from the straight piece in the last set of experiments. On the second screen the traces of the same bullets were about three inches distant, the bullet from the crooked piece passing on both screens to the left of the other; but comparing the places of these bullets on the wall, it appeared that the bullet from the crooked piece, though it diverged from the track of the other on the two screens, had now crossed that track, and was deflected considerably to the right of it; so that it was obvious, that, though the bullet from the crooked piece might at first be canted to the left, and had diverged from the track of the other bullet, with which it was compared; yet by degrees it deviated again to the right, and a little beyond the second screen crossed that track, from which it before diverged; and on the wall was deflected fourteen inches, as I remember, on the contrary side. And this experiment is not only the most convincing proof of the reality of this deflection here contended for; but is likewise the strongest confirmation, that it is brought about in the very manner, and by the very circumstances, which we have all along described.

"To prevent this irregularity, rifled barrels are made use of; and here it happens, that, when the piece is fired, the zone of the bullet follows the sweep of the rifles; and thereby, besides its progressive motion, acquires a circular motion round the axis of the piece, which circular motion will be continued to the bullet, after its separation from the piece; by which means a bullet discharged from a rifled barrel is constantly made to whirl round an axis, which is coincident with the line of its flight. And hence it follows, that the resistance on the foremost surface of the bullet is equally distributed round the pole of its circular motion; and acts with an equal effort on every side of the line of direction; so that this resistance can produce no deviation from that line. And (which is still of more importance), if by the casual irregularity of the foremost surface of the bullet, or by any other accident, the resistance should be stronger on one side of the pole of the circular motion than on the other; yet, as the place, where this greater resistance acts, must perpetually shift its position round the line in which the bullet flies, the deflection, which this inequality would occasion, if it acted constantly with the same given tendency, is now continually rectified by the various and contrary tendencies of that disturbing force, during the course of one revolution.

"This perpetual correction of a deflective effort on the foremost surface of the bullet, in consequence of the revolution of the bullet round the line of its direction, may perhaps be exemplified, by considering what happens to a castle-top, whilst it spins upon its point. For it will be easily acknowledged, that this, without its revolving motion, could not continue for the least portion of time in that situation. And if we examine how this happens, we shall find, that, though its centre of gravity is not exactly over the point it spins on, yet that inequality cannot instantly bring it to the ground according to its natural effort; because, during one revolution, the centre of gravity preponderates on every side of the top; and thereby raises it as much in one place, as it depressed it in another. And this reasoning (supposing that the tendency of the centre of gravity of the top to descend, be analogous to the action of the unequal resistance on the foremost surface of a bullet fired from a rifled barrel) will easily explain how, notwithstanding that inequality, the bullet keeps true to its track without deflection. And what is here advanced, is farther confirmed by the general practice with regard to arrows. For it is well known to every archer, that the feathers of an arrow are placed in a spiral form, so as to make the arrow spin round its axis; without which it would be obvious to the eye, that the arrow undulated in the air, and did not keep accurately to its direction. And it is owing to the same principle, that every school-boy finds himself under the necessity of making his shuttlecock spin, before he can depend upon the truth of its flight.

"This is the general theory of the motion of bullets discharged from rifled pieces; and it is found by experiment, that their actual motions correspond very well with these speculations. For the exactness which those who are dextrous in the use of these pieces attain to, is indeed wonderful; and that at such distances, that if the bullets were fired from the common pieces, in which the customary aberration takes place, not one in twenty of them could ever be traced.

"This may suffice as to the general idea of the form and convenience of a rifled piece; and here it will be expedient to insert some experiments, by which it will appear, how well it answers the purpose I have mentioned above; I mean that of keeping the ball to its regular track, by preventing that deflection, which, as we have seen, takes place in the bullets fired from common pieces.

"And first I considered, that in consequence of the reasoning about the manner in which it produces this effect; it should follow, that the same hemisphere of the bullet which lies foremost in the piece, must continue foremost during the whole course of its flight.

"To examine this particular, I took a rifled barrel carrying a bullet of six to the pound; but instead of its leaden bullet, I used a wooden one of the same size, made of a soft springy wood, which bent itself easily into the rifles without breaking. And, firing the piece thus loaded against a wall at such a distance, as the bullet might not be shivered by the blow; I always found, that the same surface, which lay foremost in the piece, continued foremost without any sensible deflection, during the time of its flight. And this was easy to be observed, by examining the bullet; as both the marks of the rifles, and the part that impinged on the wall, were sufficiently apparent.

"Now, as these wooden bullets were but the sixteenth part of the weight of those of lead; I conclude, that if there had been any unequal resistance or defective power, its effects must have been extremely sensible upon this light body; and consequently in some of the trials I made, the surface, which came foremost from the piece, must have been turned round into another situation.

"But again, I took the same piece, and loading it now with a leaden ball, I set it nearly perpendicular, sloping it only three or four degrees from the perpendicular, in the direction of the wind; and firing it in this situation, the bullet generally continued about half a minute in the air, it rising by computation to near three quarters of a mile perpendicular height.

"In these trials I found, that the bullet commonly came to the ground to the leeward of the piece, and at such a distance from it, as nearly corresponded to its angle of inclination, and to the effort of the wind; it usually falling not nearer to the piece than a hundred, nor farther from it than a hundred and fifty yards. And this is a strong confirmation of the almost steady flight of this bullet for about a mile and a half. For were the same trial made with a common piece, I doubt not that the deviation would often amount to half a mile, and perhaps considerably more; though this experiment would be a very difficult one to examine, on account of the little chance there would be of discovering where the ball fell."

It now remains to speak of the sights, which, although they do not constitute the essential part of a rifle, as they may be used with a plain bored barrel; yet as that is seldom done, and as they are always used with a rifle, it will not be proper to omit mentioning them.

It may be strictly said, that no part of the path of the bullet when fired from a rifle or musket is in a right line, as gravity acts upon the bullet the instant it quits the mouth of the piece; and although at a short distance the effect is not very perceptible, yet it is considerably so at 100 yards; and at 200 yards, the ball would probably strike the ground before it could reach the object aimed at. To remedy this inconvenience, it is found necessary to aim exactly at such a height above the object, as the ball would have been depressed to, by the power of gravity, had it been aimed at it point-blank; so that if we suppose this depression to be a foot in a hundred yards, we must aim a foot above the object. But here another inconvenience arises; for if we aim above the object by raising the muzzle of the piece, the object is excluded from our view by the intervention of the barrel; so that we are prevented from measuring the distance with the eye, and instead of one, are liable to aim two or three feet above it.

This second difficulty is removed by depressing the breech of the gun, instead of elevating the muzzle; and the quantity of the depression is measured with great nicety, by what are called the sights.

On the upper surface of the barrel, at right angles with its axis, is fixed a piece of flat thin iron (see Plate fig. 3), about six inches from the breech, and on the centre of its top, a small square notch is filed. This is called the back sight. The front sight is nothing more than the small knob of iron or brass, which is fixed on all fowling-pieces, about half an inch from the muzzle. When aim is taken, the eye is raised over the back sight, till the front sight appears through the notch, which is then brought upon the object, and forms the right line ABCD, Plate fig. 2.

But here it is evident, that the breech of the barrel is depressed in the proportion of the height of the back sight B; that the axis of the barrel forms an inclined plane with the right line ABC; that the course of the ball, if not acted upon by gravity, would be in the line ECF; and that the ball would strike at G, considerably above the object D. But being depressed in its course by the law of gravity, it will make the curve H and descend to D.

By looking at the figure it is immediately seen, that if the object aimed at had been at J, or any point nearer than D, the ball would have passed over it; and if it had been at K, or farther than D, it would have passed under it. The height of the back sight must be regulated by experiment. The government rifles have only one fixed sight, which are intended for 200 yards; but if an enemy is seen at 100 yards, aim must be taken at the knee; if at 150, below the middle. At 250 yards, the head must be aimed at; and at 300, the sight becomes useless, as it would be necessary to aim over his head, and then the inconvenience before mentioned recurs; to prevent which, the folding or additional sights are used as in figure 3, where the sight A is calculated for 150, B for 200, and C for 300 yards; beyond which distance it becomes almost useless to fire at any object of the size of a man.

Mr. Robins, who has done more on this subject than any other person, concludes an excellent paper with predicting, that whatever state shall thoroughly comprehend the nature and advantages of rifled-barrel pieces; and having facilitated and completed their construction, shall introduce into their armies their general use, with a dexterity in the management of them; will by this means acquire a superiority, which will almost equal any thing that has been done at any time by the particular excellence of any one kind of arms; and will perhaps fall but little short of the wonderful effects, which history relates to have been formerly produced, by the first inventors of fire-arms.

RIGGING of a ship, is all her cordage and ropes, belonging to her masts, yards, &c. See Ship-building.

RIGHT, in geometry, signifies the same with straight: thus a straight line is called a right one.

Right, in law, not only denotes property, for which a writ of right lies, but also any title or claim, either by virtue of a condition, mortgage, &c. for which no action is given by law, but an entry only.

By stat. 1 Will. and Mar. cap. ii. the following particulars relating to the ill conduct of king James II. were declared to be illegal, and contrary to the antient rights and liberties of the people, viz. his exercising a power of dispensing with, and suspending of, laws; his levying money without consent of parliament; violating the freedom of elections; causing partial and corrupt jurors to be returned on trials, excessive bail to be taken, and excessive fines to be imposed, as well as cruel punishments to be inflicted, &c.

RIM, in a watch, or clock, the edge or border of the circumference or circular part of a wheel.

RING, in navigation and astronomy, a brass instrument, made in the form of a ring, and serving to take altitudes of the sun. See Plate Miscel. fig. 209.

At C is a small hole, in the direction CD, which is perpendicular to CE; this hole is precisely 45° from A, and CE is parallel to the vertical diameter AB. From C, as a centre, they describe a quadrant of a circle CED; which being nicely divided into 90°, they mark upon the internal surface of the ring the places where rays, drawn from C to these degrees, cut the said surface.

To use this ring, they hold it up by the swivel, and turn the side with the hole C towards the sun; and then the sun-beams passing through the hole, make a luminous spot among the degrees, whereby the altitude is found. Some prefer the ring to the astrolabe, by reason its divisions are larger; however, it is far from being exact enough to be much depended on in astronomical observations, which are better made by quadrants. See Astrolabe, and Quadrant.

RIOT, in law. When three persons or more shall assemble themselves together, with an intent mutually to assist one another, against any who shall oppose them in the execution of some enterprise of a private nature, with force or violence, against the peace, or to the manifest terror of the people, whether the act intended was of itself lawful or unlawful: if they only meet for such a purpose or intent, though they shall after depart of their own accord without doing any thing, this is an unlawful assembly. 1 Haw. 155.

If after their first meeting, they shall move forwards towards the execution of any such act, whether they put their intended purpose into execution or not; this according to the general opinion is a riot. Id.

By 34 Ed. Ire. c. 1, it is enacted, that if a justice find persons riotously assembled, he alone has not only power to arrest the offenders, and bind them to their good behaviour, or imprison them if they do not offer good bail: but he may also authorize others to arrest them, by a bare verbal command, without other warrant; and by force thereof, the persons so commanded, may pursue and arrest the offenders in his absence as well as presence. It is also said, that after any riot is over, any one justice may send his warrant to arrest any person who was concerned in it, and that he may send him to gaol till he shall find sureties for his good behaviour. 1 Haw. 160.

The punishment of unlawful assemblies, if to the number of twelve, may be capital, according to the circumstances which attend them: but from the number of three to eleven, is by fine and imprisonment only. The same is the case by riots and routs by the common law, to which the pillory in very enormous cases has been sometimes superadded. 4 Black. c. 11.

By stat. 1 Geo. I. cap. 5, if any persons to the number of twelve or more, unlawfully and riotously assembled, continue together for an hour, after being required, by a justice of the peace, or other magistrate, to disperse, they shall be deemed guilty of felony without benefit of clergy. However, prosecutions upon this statute must be begun within one year after the offence is committed.

RITE, among divines, denotes the particular manner of celebrating divine service, in a particular country.

RITTERA, a genus of the class and order polyandria monogynia. The calyx is four-leaved; petal one; legume one-celled, two-valved. There are five species, trees of the West Indies.

RITUAL, a book directing the order and manner to be observed in celebrating religious ceremonies, and performing divine service, in a particular church, diocese, order, or the like.

RIVERS. With any person who has carefully observed the course of rivers, and traced them to their sources, there can be little doubt that they are formed by the confluence of springs, or of the little streams or rivulets that issue from them; with perhaps the exception of those rivers which proceed from lakes, where the reservoir is ready-formed, and generally by the same means.

In the beginning of the present century, the philosophical world was agitated by a debate concerning the origin of those waters which are necessary for the supply of rivers, &c. One party contended strongly for the existence of a large mass of water within the bowels of the earth, which supplied not only the rivers but the ocean itself; at the head of these we may place the ingenious but fanciful Burnet. The French philosophers, on the contrary, asserted, that the waters of the ocean were conveyed back by some subterraneous passages to the land, and being filtrated in their passage, returned again to the sea in the course of the rivers; but this opinion appears contrary to all the known principle of hydrostatics.

In opposition to these hypotheses, our illustrious countryman Halley contended that the process of evaporation, and the immense deposition of water in consequence of it, were fully adequate to the whole supply. If, indeed, we consider the immense quantity of water which is continually carried up into the atmosphere by evaporation (see EVAPORATION), and consider that this is a process which is continually going on, not only from the ocean but from the rivers themselves, and from the whole surface of the earth, we shall see but little reason to doubt of Dr. Halley's hypothesis; but may reasonably conclude, that this kind of circulation is carried on through all nature; and that the sea receives back again through the channel of the rivers, that water which it parts with to the atmosphere.

All rivers have their source either in mountains, or elevated lakes; and it is in their descent from these, that they acquire that velocity which maintains their future current. At first their course is generally rapid and headlong; but it is retarded in its journey by the continual friction against its banks, by the many obstacles it meets to divert its stream, and by the plane's generally becoming more level as it approaches towards the sea.

Rivers, as every body has seen, are always broadest at the mouth, and narrower towards their source. But what is less known, and probably more deserving curiosity, is, that they run in a more direct channel as they immediately leave their sources; and that their sinuosities and turnings become more numerous as they proceed. It is a certain sign among the savages of North America, that they are near the sea, when they find the rivers winding, and every now and then changing their direction. And this is even now become an indication to the Europeans themselves, in their journeys through those trackless forests. As those sinuosities, therefore, increase as the river approaches the sea, it is not to be wondered at, that they sometimes divide, and thus disembogue by different channels. The Danube disembogues into the Euxine by seven mouths; the Nile, by the same number; and the Wolga, by seventy.

The largest rivers of Europe are, first, the Wolga, which is about six hundred and fifty leagues in length, extending from Rescnow to Astrachan. It is remarkable of this river, that it abounds with water during the summer months of May and June; but all the rest of the year is so shallow as scarcely to cover its bottom, or allow a passage for loaded vessels that trade up its stream. The next in order is the Danube. The course of this is about four hundred and fifty leagues, from the mountains of Switzerland to the Black Sea. The Don, or Tanais, which is four hundred leagues from the source of that branch of it called the Softna, to its mouth in the Euxine Sea. In one part of its course it approaches near the Wolga; and Peter the Great had actually begun a canal, by which he intended joining those two rivers; but this he did not live to finish. The Nieper, or Borysthenes, which rises in the middle of Muscovy, and runs the course of three hundred and fifty leagues, to empty itself into the Black Sea. The Old Cossacks inhabit the banks and islands of this river; and frequently cross the Black Sea, to plunder the maritime places on the coasts of Turkey. The Dwina, which takes its rise in a province of the same name in Russia, that runs a course of three hundred leagues, and disembogues into the White Sea, a little below Archangel.

The largest rivers of Asia are, the Hoanho, in China, which is eight hundred and fifty leagues in length, computed from its source at Raja Ribron, to its mouth in the Gulph of Changi. The Jenisca of Tartary, about eight hundred leagues in length, from the lake Selinga to the Icy Sea. This river is, by some, supposed to supply most of that great quantity of drift-wood which is seen floating in the seas, near the Arctic circle. The Oby, of five hundred leagues, running from the lake of Kila into the Northern Sea. The Amour, in Eastern Tartary, whose course is about five hundred and seventy-five leagues, from its source to its entrance into the sea of Kamtschatka. The Kiam, in China, five hundred and fifty leagues in length. The Ganges, one of the most noted rivers in the world, and about as long as the former. It rises in the mountains which separate India from Tartary; and running through the dominions of the Great Mogul, discharges itself by several mouths into the bay of Bengal. It is not only esteemed by the Indians for the depth and pureness of its stream, but for a supposed sanctity which they believe to be in its waters. It is visited annually by several hundred thousand pilgrims, who pay their devotions to the river as to a god; for savage simplicity is always known to mistake the blessings of the Deity for the Deity himself. They carry their dying friends, from distant countries, to expire on its banks, and to be buried in its stream. The water is lowest in April or May; but the rains beginning to fall soon after, the flat country is overflowed for several miles, till about the end of September; the waters then begin to retire, leaving a prolific sediment behind, that enriches the soil, and, in a few days time, gives a luxuriance to vegetation, beyond what can be conceived by an European. Next to this may be reckoned the still more celebrated river Euphrates. This rises from two sources, northward of the city Erzerum, in Turcomania; and unites about three days journey below the same, whence, after performing a course of five hundred leagues, it falls into the Gulph of Persia, fifty miles below the city of Bassora in Arabia. The river Indus is extended, from its source to its discharge into the Arabian sea, four hundred leagues.

The largest rivers of Africa are: the Senegal, which runs a course of not less than eleven hundred leagues, comprehending the Niger, which some have supposed to fall into it. Later accounts, however, seem to affirm that the Niger is lost in the sands, about three hundred miles up from the western coasts of Africa. Be this as it may, the Senegal is well known to be navigable for more than three hundred leagues up the country; and how much higher it may reach is not yet discovered, as the dreadful fatality of the inland parts of Africa not only deters curiosity, but even avarice, which is a much stronger passion. The celebrated river Nile is said to be nine hundred and seventy leagues, from its source among the mountains of the Moon, in Upper Ethiopia, to its opening into the Mediterranean Sea. Upon its arrival in the kingdom of Upper Egypt, it runs through a rocky channel, which some late travellers have mistaken for its cataracts. In the beginning of its course, it receives many lesser rivers into it; and Pliny was mistaken, in saying that it received none. In the beginning also of its course, it has many windings; but, for above three hundred leagues from the sea, runs in a direct line. Its annual overflowings arise from a very obvious cause, which is almost universal with the great rivers that take their source near the Line. The rainy season, which is periodical in those climates, floods the rivers; and as this always happens in our summer, so the Nile is at that time overflown. From these inundations the inhabitants of Egypt derive happiness and plenty; and, when the river does not arrive at its accustomed height, they prepare for an indifferent harvest. It begins to overflow about the 17th of June; it generally continues to augment for forty days, and decrease in about as many more. The time of increase and decrease, however, is much more inconsiderable now than it was among the antients. Herodotus informs us, that it was a hundred days rising, and as many falling; which shews that the inundation was much greater at that time than at present. M. Buffon has ascribed the present diminution, as well to the lessening of the mountains of the Moon, by their substance having so long been washed down with the stream, as to the rising of the earth in Egypt, that has for so many ages received this extraneous supply. But we do not find, by the buildings that have remained since the times of the antients, that the earth is much raised since then. Besides the Nile in Africa, we may reckon Zara, and the Coanza, from the greatness of whose openings into the sea, and the rapidity of whose streams, we form an estimate of the great distance whence they come. Their courses, however, are spent in watering deserts and savage countries, whose poverty or fierceness have kept strangers away.

But of all parts of the world, America, as it exhibits the most lofty mountains, so also it supplies the largest rivers. The principal of these is the great river Amazons, which, from its source in the lake of Lauricocha, to its discharge into the Western Ocean, performs a course of more than twelve hundred leagues. The breadth and depth of this river is answerable to its vast length; and, where its width is most contracted, its depth is augmented in proportion. So great is the body of its waters, that other rivers, though before the objects of admiration, are lost in its bosom. It proceeds after their junction, with its usual appearance, without any visible change in its breadth or rapidity; and, if we may so express it, remains great without ostentation. In some places it displays its whole magnificence, dividing into several large branches, and encompassing a multitude of islands; and at length, discharging itself into the ocean, by a channel of an hundred and fifty miles broad. Another river, that may almost rival the former, is the St. Lawrence, in Canada, which rising in the lake Assiniboils, passes from one lake to another, from Christinaux to Alempigo; and thence to lake Superior; thence to the lake Hurons; to lake Erie; to lake Ontario; and, at last, after a course of nine hundred leagues, pours their collected waters into the Atlantic Ocean. The river Mississippi is more than seven hundred leagues in length, beginning at its source near the lake Assiniboils, and ending at its opening into the Gulph of Mexico. The river Plata runs a length of more than eight hundred leagues from its source in the river Parana, to its mouth. The river Oroonoko is seven hundred and fifty leagues in length, from its source near Pasto, to its discharge into the Atlantic ocean.

Such is the amazing length of the greatest rivers; and even in some of these, the most remote sources very probably yet continue unknown. In fact, if we consider the number of rivers which they receive, and the little acquaintance we have with the regions through which they run, it is not to be wondered at that geographers are divided concerning the sources of most of them. As among a number of roots by which nourishment is conveyed to a stately tree, it is difficult to determine precisely that by which the tree is chiefly supplied; so among the many branches of a great river, it is equally difficult to tell which is the original. Hence it may easily happen, that a similar branch is taken for the capital stream; and its runnings are pursued and delineated, in prejudice of some other branch that better deserved the name and the description. In this manner, in Europe, the Danube is known to receive thirty lesser rivers; the Wolga thirty-two or thirty-three. In Asia, the Hohanno receives thirty-five; the Jenisca above sixty; the Oby as many; the Amour about forty; the Nanquin receives thirty rivers; the Ganges twenty; and the Euphrates about eleven. In Africa, the Senegal receives more than twenty rivers; the Nile receives not one for five hundred leagues upwards, and then only twelve or thirteen. In America, the river Amazons receives above sixty, and those very considerable; the river St. Lawrence about forty, counting those which fall into its lakes; the Mississippi receives forty; and the river Plata above fifty.

The inundations of the Ganges and the Nile have been already mentioned, and it might be added, that almost all great rivers have their periodical inundations from similar causes. The author already quoted observes, that, "besides these annually periodical inundations, there are many rivers that overflow at much shorter intervals. Thus most of those in Peru and Chili have scarce any motion by night; but upon the appearance of the morning sun they assume their former rapidity; this proceeds from the mountain snows, which, melting with the heat, encrease the stream, and continue to drive on the current while the sun continues to dissolve them."

There are some rivers which are said to lose themselves in chasms under the earth, and to flow for several miles in secret and undiscovered channels. On this circumstance is founded one of the most beautiful fables of antiquity, relative to the fountain of Arethusa, in Sicily. The same thing is affirmed of the Rhine, and even of the river Mole, in Surrey, which, from this circumstance derives its name. With respect to the two latter rivers, however, some doubts are entertained of the fact.

On this subject there is a memoir of the academy of sciences lately published, by the abbé Guettard. "It is very surprising (he observes) if we reflect on it, that a river in its course, which is very often very extensive, should not meet with spongious soils to swallow up its waters, or gulphs in which they are lost; nevertheless, as there has been hitherto known but a small number of rivers whose waters thus disappear, this phenomenon has been accounted very extraordinary, both by the ancients and moderns. Mr. Guettard next describes what he has observed in several rivers of Normandy, which are lost and afterwards appear again; these are five in number, viz. the Rille, the Ithon, the Aure, the river of Sap-Audré, and the Drôme. The three first disappear gradually, and then come in sight again; the fourth loses itself entirely by degrees, but afterwards re-appears; the fifth loses some of its water in its course, and ends by precipitating itself into a cavity, whence it is never seen to rise again.

What seems to occasion the loss of the Rille, the Ithon, and the Aure, is the nature of the soil through which they pass. M. Guettard has observed that it is in general porous, and composed of a thick sand, the grains of which are not well compacted together; it sinks suddenly down by its own weight in some places, and there forms great holes; and when the water overflows the meadows, it frequently makes many cavities in several parts of them. If we therefore suppose inequalities in the channels of these rivers, and that there are certain places in which the water stagnates longer than in others, it must there dilute the ground, if we may use that expression; and having carried away the parts which united the grains of sand together, those grains will become afterwards no other than a kind of sieve, through which the waters will filtrate themselves, provided nevertheless that they find a passage under ground through which they may run. This conjecture appears to be so well founded, that each of these three rivers loses itself nearly in the same manner, that is, through cavities which the people of the country call betoirs, and which swallow up more or less according to their largeness. M. Guettard, who has carefully examined them, remarks, that these betoirs are holes in the form of a tunnel, whose diameter and aperture is at least two feet, and sometimes exceeds eleven; and whose depth varies in like manner from one and two feet, to five, six, and even twenty. The Rille during the summer season loses almost all its water in the space of two short leagues; the Ithon does very near the same. But M. Guettard observes something curious concerning this river, that formerly it was not lost, but kept its course without any interruption, as appears by the history of the country; very likely the mud, which had been collected together in several parts of its channel, might have occasioned the waters remaining in others, and have caused many betoirs. This is the more likely, as the mud having been collected together in the bed of the river Aure, it appears that, in consequence, the cavities were greatly encreased, which makes it lose itself much sooner than formerly. Besides, possibly an earthquake happening in the country might have caused several subterraneous canals through which the water of the Ithon has forced its way. In effect, it appears, that a soil's being porous is not sufficient to cause the loss of a river; for if it was, then to do so it would occasion many fens round about, nor would it renew its course after having disappeared a certain time; it must besides, find ways under ground through which it may take its course. M. Guettard seems also mcuh inclined to believe, that there are, in these parts, subterraneous cavities through which the waters may flow; and in consequence of this he reports a number of facts, all tending to prove the truth of it, or at least to prove that there must be hollow quarries serving for strainers to these waters. Upon which occasion he goes into a discussion of this question: Are there any subterraneous rivers, and is the prepossession of some persons in favour of this particular well founded? He makes it appear by several instances which he quotes, and by many reasons which he alleges, that there are at least very great presumptions in favour of this opinion. We are too apt not to look beyond the exterior of things: we feel resistance upon the surface of the earth; when we go deep, we often find it compact. It is therefore hard for us to imagine that it can contain subterraneous cavities sufficient to form channels for hidden rivers, or for any considerable body of water; in a word, that it can contain vast caverns; and yet every thing seems to indicate the contrary. A fact that is observed in the betoirs of the rivers concerning which we have spoken, and particularly of the Rille, proves in some measure that there are considerable lakes of waters in the mountains which limit its course: this fact is, that in winter the greatest part of their betoirs become springs, which supply anew the river's channel with as much water as they had absorbed from it during the summer. Now from whence can that water come, unless from the reservoirs or lakes that are inclosed in the mountains, which being lower than the river in summer, absorb its water, and being higher in winter by the rain they receive, send it back again in their turn?

M. Guettard strengthens this conjecture by several instances that render it very probable: he remarks at the same time, that this alternate effect of the betoirs swallowing up the water and restoring it again, causes perhaps an invincible obstacle to the restraining of the water within the channel of the river. It has indeed been several times attempted to stop those cavities; but the water returns with such violence in winter, that it generally carries away the materials with which they were stopped.

The river of Sap-André is lost in part, as we have before said, in the same manner as the Ithon and the Rille; but there is something more remarkable in it than in those rivers; to wit, that at the extremity of its course, where there is no perceptible cavity, it is ingulphed, but without any fall; the water passes between the pebbles, and it is impossible to force a stick into that place any further than into the betoirs of which we have spoken. What makes this river take that subterraneous direction, is an impediment which its stream meets with in that place; it is there stopped by a rising ground six or seven feet high, whose bottom it has very likely undermined, to gain a free passage, not having been able to make its way over it. At some distance it appears again; but in winter, as there is a greater quantity of water, it passes over that eminence, and keeps an uninterrupted course.

Lastly, the Drôme, after having lost some of its water in its course, vanishes entirely near the pit of Soucy; in that place it meets with a sort of subterraneous cavity near 25 feet wide, and more than 15 deep, where the river is in a manner stopped, and into which it enters, though without any perceptible motion, and never appears again.

M. Guettard finishes this memoir with some observations upon the Ierre. This river is lost in the same manner as the Rille; and though it is very near Paris, this singularity is unknown to almost every body; was it not for the account of M. l'Abbé le Bœuf, M. Guettard would have been also ignorant of it. And as he thinks the chief object of a naturalist's observation ought to be the public good, he examines the means which might be employed to restrain the water of the Ierre. The same object has made him add a description of the manner how the Rhone is lost, or rather how its course is disturbed; for it is now very certain that it does not lose itself, but that its channel is extremely confined, in the place where it was pretended that it lost itself, by two mountains, between whose feet it runs. M. Guettard makes it appear that it might not be impossible to widen that place, and give a sufficient channel to the river; which would render it navigable, and be of vast utility to all the country.

The many advantages which accrue to a country from an abundance of rivers, especially large navigable ones, are too obvious to require any particular detail; but the disadvantages and calamities occasioned by them are frequently no less obvious and fatal. Whole tracts of country are sometimes overflowed on a sudden, and every thing swept away at once; or if the deluge proceeds not such a length, yet by the quantity of stagnating water which is left, marshes are produced, which bring on diseases in the neighbouring parts. It becomes therefore an object well worthy the public attention, how to secure the banks of rivers, or to form their channels in such a manner that the superfluous water may be carried off into the ocean without producing the mischievous effects abovementioned. In a treatise on rivers and canals published in the Phil. Trans. vol. 69. by Mr. Mann, he treats this subject at great length. Having laid down a number of theorems concerning the descent of the water in rivers, he points out a method of determining whether the motion of a river in any particular place is derived from the inclination of the bottom of its channel, or merely from the pressure of the upper parts of the water upon the lower. "For this purpose," says he, "a pole must be thrust down to the bottom, and held perpendicularly to the current of the water, with its upper end above the surface; if the water swells and rises immediately against the pole, it shows that its flowing is by virtue of a preceding declivity; if, on the contrary, the water stops for some moments before it begins to rise against the pole, it is a proof that it flows by means of the compression of the upper waters upon the lower."

The best and most simple method of measuring the velocity of the current of a river, according to our author, is as follows: "Take a cylindrical piece of dry light wood, and of a length something less than the depth of the water in the river; round one end of it let there be suspended as many small weights as may be necessary to keep up the cylinder in a perpendicular situation in the water, and in such a manner that the other end of it may just appear above the surface of the water. Fix to the centre of that end which appears above water a small and straight rod precisely in the direction of the cylinder's axis; to the end that, when the instrument is suspended in the water, the deviations of the rod from a perpendicularity to the surface of it may indicate which end of the cylinder advances the fastest, whereby may be discovered the different velocities of the water at different depths; for if the rod inclines forwards according to the direction of the current, it is a proof that the surface of the water has the greatest velocity; but if it inclines back, it shows that the swiftest current is at the bottom; if it remains perpendicular, it is a sign that the velocities at the surface and bottom are equal.

"This instrument being placed in the current of a river or canal receives all the percussions of the water throughout the whole depth, and will have an equal velocity with that of the whole current from the surface to the bottom at the place where it is put in; and by that means may be found, both with ease and exactness, the mean velocity of that part of the river for any determinate distance and time.

"But to obtain the mean velocity of the whole section of the river, the instruments must be put successively both in the middle and towards the sides, because the velocities at those places are often very different from each other. Having by this means found the difference of time required for the currents to run over an equal space, or the different distances run over in equal times; the mean proportional of all these trials, which is found by dividing the common sum of them all by the number of trials, will be the mean velocity of the river or canal.

"If it is required to find the velocity of the current only at the surface, or at the middle, or at the bottom, a sphere of wood, of such a weight as will remain suspended in equilibrium with the water at the surface or depth which we want to measure, will be better for the purpose than a cylinder, because it is only affected by the water of that part of the current where it remains suspended.

It is a very easy guide both to the cylinder and the globe in that part which we want to measure, by means of two threads, or small cords, which two persons must hold and direct, one on each side of the river; taking care at the same time neither to retard nor accelerate the motion of the instrument."

Our author next proceeds to deduce from his theory the best methods of removing the defects and inconveniencies which must necessarily happen to rivers and canals in a series of years. From his theory he draws the following conclusion: that the deeper the waters are in their bed in proportion to its breadth, the more their motion is accelerated; so that their velocity increases in an inverse ratio of the breadth of the bed, and also of the greatness of the section; whence are deduced the two following universal practical rules: 1st. To augment the velocity of water in a river or canal, without augmenting the declivity of the bed, we must increase the depth and diminish the breadth of its bed. 2dly. But to diminish the velocity of water in a river or canal, we must, on the contrary, increase the breadth and diminish the depth of its bed.

The above proposition is perfectly conformable to observation and experience: for it is constantly seen, that the current is the swiftest where the waters are deepest and the breadth of the bed the least, and that they flow slowest where their depth is the least and the breadth of the bed the greatest. "The velocity of the waters" says M. de Buffon, "augments in the same proportion as the section of the channel through which they pass diminishes, the force of impulsion from the back waters being supposed always the same. Nothing," continues he, "produces so great a diminution in the swiftness of a current as its growing shallow; and on the contrary, the increase of the volume of water augments its velocity more than any other cause whatever." The celebrated Wolfe in his hydraulics assures us, that "it is a constant and universal practice, for accelerating the current of waters, to deepen the bed, and at the same time to render it narrower."

When the velocity which a river has acquired by the elevation of its springs and the impulse of the back water, is at last totally destroyed by the different causes of resistance becoming exactly equal to, or greater than, the first, the bed and current at the same time being horizontal, nothing else remains to propagate the motion, except the sole perpendicular compression of the upper waters upon the lower, which is always in a direct ratio of their depth. But this necessary resource, this remaining cause of motion in rivers, augments in proportion as all the others diminish, and as the want of it increases; for as the waters of rivers in extensive plains lose the acceleration of motion acquired in their descent from their springs, their quantity accumulates in the same bed by the junction of several streams together, and their depth increases in consequence. This junction and successive accumulation of many streams in the same bed, which we see universally in a greater or lesser degree in all rivers throughout the known world, and which is so absolutely necessary to the motion of their waters, can only be attributed, says Signor Guglielmini, to the infinite wisdom of the supreme Author of Nature.

The velocities of flowing waters is very far from being in proportion to the quantity of declivity in their bed. If it was a river whose declivity is uniform and double to that of another, it ought only to run with double the swiftness when compared to it; but in effect it is found to have a much greater, and its rapidity, instead of being only double, will be triple, quadruple, and sometimes even more; for its velocity depends much more on the quantity and depth of the water, and on the compression of the upper waters on the lower, than on the declivity of the bed. Consequently, whenever the bed of a river or canal is to be dug, the declivity must not be distributed equally throughout the whole length; but, to give a swifter current to the water, the declivity must be much greater in the beginning of its course than towards the end where it disembogues itself, and where the declivity must be almost insensible, as we see is the case in all natural rivers; for when they approach near the sea, their declivity is little or nothing; yet they flow with a rapidity which is so much greater, as they contain a greater volume of water; so that in great rivers, although a large extent of their bed next the sea should be absolutely horizontal, and without any declivity at all, yet their waters do not cease to flow, and to flow even with great rapidity, both from the impulsion of the back-waters, and from the compression of the upper waters upon the lower in the same section.

Whoever is well acquainted with the principles of the higher geometry, will easily perceive that it would be no difficult matter so to dig the bed of a canal or river, that the velocity of the current should be every where equal. It would be only giving it in the form of a curve along which a moving body should recede from a given point, and describe spaces every where proportional to the times, allowance being made for the quantity of effect of the compression of the upper waters upon the lower. This curve is what is called the horizontal isochronic, being the flattest of an infinity of others which would equally answer the problem where fluids were not concerned.

All obstacles whatever in the bed of a river or canal, such as rocks, trunks of trees, banks of sand and mud, &c. must necessarily hinder proportionably the free running off of the water; for it is evident, that the waters so far back from these obstacles, until the horizontal level of the bottom of the bed becomes higher than the top of the obstacles, must be entirely kept up and hindered from running off in proportion. Now as the waters must continue to come down from their sources, if their free running off is hindered by any obstacles whatever, their relative height back from them must necessarily be increased until their elevation, combined with the velocity of their current proceeding from it, is arrived to such a pitch at the point where the obstacles exist, as to counterbalance the quantity of opposition or impediment proceeding thence, which frequently does not happen until all the lower parts of the country round about are laid under water.

Now it is certain from all experience, that the beds of rivers and canals in general are subject to some or others of the obstacles above-mentioned. If rocks or trees do not bar their channels, at least the quantity of sand, earth, and mud, which their streams never fail to bring down, particularly in floods, and which are unequally deposited according to the various windings and degrees of swiftness in the current, must unavoidably, in course of time, fill up, in part, different places in the channel, and hinder the free running off of the back-waters. This is certainly the case, more or less, in all rivers, and in all canals of long standing, as is notorious to all those well acquainted with them. Hence, if these accidents are not carefully and with a constant attention prevented, inundations occur which sometimes lay waste whole districts, and ruin the finest tracts of ground, by covering them with sand; hence rivers become unnavigable, and canals useless for the purposes for which they were constructed. Canals, in particular, as their waters for the most part remain stagnant in them, are still more liable than rivers to have their beds fill up by the subsiding of mud, and that especially for some distance above their sluices; insomuch, that if continual care is not taken to prevent it, or remedy it as often as it happens, they will soon become incapable of receiving and passing the same vessels as formerly. Nay, the very sluices themselves, if the floors of their bottoms are not of a depth conformable to the bed of the canal, will produce the same accidents as those we have been speaking of; for if they are placed too low, they will be continually filling up with sand or mud; if too high, they have the same effect as banks or bars in the bed of a river, that is, they hinder all the back-waters under their level from running off, and soon fill up the bed to that height by the subsiding of mud. This effect is much accelerated by the shutting of the lower sluices, which makes a great volume of water flow back to those next above them, till the whole is filled and become stagnant. Now it is evident, that this state of things must contribute far more to the subsidency of mud, and all other matters brought down by the waters in canals, than can be the case in rivers whose currents constantly flow.

The waters of all rivers and canals are from time to time muddy; their streams, particularly during rains and floods, carry along with them earth and other substances which subside in those places where their currents are the least, by which their beds are continually raised; so that the successive increase of inundations in rivers, and of unfitness for navigation in canals, when they are neglected and left to themselves, is a natural and necessary consequence of the state of things, which no intelligent person can be at a loss to account for; and yet whole countries remain in this habitual state of negligence, to their very great detriment.

Having thus shown the principal accidents which rivers and canals are liable to, with the causes of them, our author proceeds to point out the most efficacious methods of preventing them, or at least of diminishing their effects. They flow immediately from the principles laid down in his essay, and do not need many words to make them completely understood. A work of this kind, he observes, if it is properly conducted, must be begun at the lower end of the river or canal: that is, at that end where their waters are discharged into the sea, or where they fall into some other greater river or canal, whence their waters are carried off without further hindrance. If it is a river whose bed, by being filled up with sand, mud, or other obstacles, and by being otherwise become irregular in its course, is often subject to its inundations, and incapable of internal navigation, the point, from which the work must be begun and directed throughout all the rest of the channel, is from the lowest water-mark of spring-tides on the shore at the mouth of the river, or even something below it, if it can be done; though this part will soon fill up again by the sand, mud, &c. which the tides cease not to roll in.

If it is a canal whose bed is to be dug anew, or one already made, which is to be cleaned and deepened from the sea-shore or some large river back into the country, and where no declivity is to be lost, as is the case in all flat countries; the work must be begun, and the depth of the whole channel directed, from the lower water-mark of spring-tides, if the mouth is to the sea, or from such a depth in the channel of the river, if the canal falls into one, that there may be such a communication of water from the canal to the river, in all situations of the current, as may let boats freely pass from one to the other. This, of course, must also direct the depth of the floor of the last sluice towards the mouth of the canal, be it to the sea or into a river. If the bottom or floor of a sluice already constructed is too low, it will soon fill up with sand or mud, and hinder the gates from opening, unless it is continually cleaned out: if, on the contrary, this floor is too high, and in a canal whose natural declivity is too little for the free current of the water, as is generally the case in Holland and Flanders, all depth of the bed of the canal below the horizontal level of the bottom of the sluice will serve to no manner of purpose, either for navigation, or for carrying off the back-waters, but will soon fill up with mud, in spite of all means used to the contrary, except that of digging it continually anew to no manner of purpose.

Setting off from this determinate point, at the mouth of a river, or at the bottom of the last sluice upon a canal, which are to be cleaned and deepened; the work must be carried on, in consequence uniformly throughout their whole course backwards into the country as far as is found necessary for the purposes intended. This is to be done after the following manner:

1st. One must dig up and carry away all irregularities in the bottom and sides of the bed, such as banks of sand and mud, rocks, stumps or trunks of trees, and whatever else may cause an obstacle to the regular motion of the water, and to the free passage of vessels upon it.

2dly. If the declivity of the bed should be still too little to give a sufficient current to carry off the water as often and as fast as is necessary, the whole bed itself must be regularly deepened, and what is dug out from the bottom must be laid upon the sides, to render it narrower in proportion to its depth.

3dly. Wherever the banks are too low to contain the stream in all its situations, they must be sufficiently raised; which may be conveniently done with what is dug out from the bed; and the whole being covered with green turf will render these banks firm and solid against the corrosion of the water. It is proper at all times to lay upon the banks what is dug from the bed, by which they are continually strengthened against the force of the current.

4thly. It is often necessary to diminish the windings and sinuosities in the channel as much as possible, by making new cuts whereby its course may approach towards a right line. This is a great resource in flat countries subject to inundations; because thereby all the declivity of a great extent of the river, through its turns and windings, may be thrown into a small space by cutting a new channel in a straight line; as may generally be done without obstacle in such countries as we are speaking of, and hereby the velocity of the current will be very greatly augmented, and the back-waters carried off to a surprising degree.

5thly. Wherever there is a confluence of rivers or canals, the angle of their junction must be made as acute as possible, or else the worst of consequences will arise from the corrosion of their respective streams; what they carry off from the sides will be thrown into irregular banks in the bottom of the bed. This acute angle of the junction may always be procured by taking the direction at some distance from the point of confluence.

6thly. Wherever the sides or banks of a river are liable to a more particular corrosion, either from the confluence of streams, or from irremediable windings and turns in the channel, they must be secured against it as much as possible by weirs: for this corrosion not only destroys the banks, and alters by degrees the course of the river, but also fills up the bed, and produces all the bad effects we have spoken of above.

7thly. But the principal and greatest attention in digging the beds of rivers and canals must be had to the quantity and form of their declivity. This must be done uniformly throughout their whole extent, or so much of it as is necessary for the purposes in hand, according to the principles laid down. Conformable thereto, the depths of their beds, and of the floors of their sluices, at the mouths where they discharge their waters, being fixed, the depth of the rest of the beds, and the quantity of declivity, must be regulated in consequence thereof, so as to increase regularly the quantity of the declivity in equal spaces the further we recede from their mouths, and proceed towards their sources or to the part where the regular current is to take place.

If the depth and volume of water in a river or canal is considerable, it will suffice, in the part next the mouth, to allow one foot perpendicular of declivity through six, eight, or even, according to Deschales, ten thousand feet in horizontal extent; at most it must not be above one in six or seven thousand. Hence the quantity of declivity in equal spaces must slowly and gradually increase as far as the current is to be made fit for navigation; but in such a manner, as that at this upper end there may not be above one foot of perpendicular declivity in four thousand feet of horizontal extent. If it is made greater than that in a regular bed containing a considerable volume of water, the current will be so strong as to be found very unfit for the purposes of navigation.

Mr. Mann calls the centre of the current, or more properly, line of greatest current, that line which passes through all the sections of a river, in the point where the velocity of the current is the greatest of all. If the current of a river is regular, and in a right line, its centre or line of greatest velocity will be precisely in the centre of the sections; but on the contrary, if the bed is irregular and full of turns and windings, the centre, or line of greatest current, will likewise be irregular, and often change its distance and direction with regard to the centres of the sections through which the waters flow, approaching successively, and more or less, to all parts of the bed, but always in proportion and conformably to the irregularities in the bed itself.

This deviation of the line of greatest current from the centres of the sections through which it passes, is a cause of many and great changes in the beds of rivers, such as the following:

1st. In a straight and regular bed, the greatest corrosion of the current will be in the middle of the bottom of the bed; because it is that part which is nearest to the line of greatest current, and at the same time which is most acted upon by the perpendicular compression of the water. In this case, whatever matters are carried off from the bottom will be thrown, by the force of the current, equally toward the two sides, where the velocity of the steam is the least in the whole section.

2dly. If the bed is irregular and winding, the line of greatest current will be thrown towards one side of the river, where its greatest force will be exerted in proportion to the local causes which turn it aside: in short turns of a river there will be a gyration, or turning round of the stream, from its beating against the outer side of the angle; this part will be corroded away, and the bottom near it excavated to a great depth. The matters so carried off will be thrown against the opposite bank of the river where the current is the least, and produce a new ground called an alluvion.

3dly. Inequalities at the bottom of a river retain and diminish the velocity of the water, and sometimes may be so great as to make them reflow; all these effects contribute to the subsiding of sand, earth, and other matters, which cease not to augment the volume of the obstacles themselves, and produce shallows and banks in the channel. These in time, and by a continuance of the causes, may become islands, and so produce great and permanent changes and irregularities in the beds of rivers.

4thly. The percussions of the centre of the current against the sides of the bed are so much the greater as they are made under a greater angle of incidence; whence it follows, that the force of percussion, and the quantity of corrosion and detriment done to the banks and weirs of rivers, and to the walls of buildings which are exposed to that percussion, are always in a direct compound proportion of the angle of incidence, of the greatness and depth of the section together, and of the quantity of velocity of the current.

5thly. It may happen in time, that the excavation of the bottom, and the corrosion of the sides, will have so changed the form of the bed as to bring the force of percussion into equilibrium with the velocity and direction of the current; in that case, all further corrosion and excavation of the bed ceases.

6thly. This gives the reason why when one river falls into another almost in a perpendicular direction, and makes with it too great an angle of incidence, this direction is changed in time, by corrosions and alluvions, into an angle much more acute, till the whole comes into equilibrium.

7thly. So great and such continued irregularities, from local causes, may happen in the motion of a river as will entirely change its antient bed, corrode through the banks where they are exposed to the greatest violence of percussion of the stream, and open new beds in grounds lower than the old one is become.

8thly. Hereupon the state of the old bed will entirely depend on the quantity of water, and on the velocity and direction of the current in the new one; for immediately after this division of the waters into two beds is made, the velocity of the current in the old one will be diminished in proportion to its less depth. In consequence, the waters will precipitate more of their mud, &c. in equal spaces than they did before; which will more and more raise up the bottom, sometimes even till it becomes equal with the surface of the stream. In this case, all the water of the river will pass into the new bed, and the old one will remain entirely dry. It is well known that this has happened to the Rhine near Leyden, and to many other rivers.

9thly. Hence the cause of the formation of the new branches and mouth, by which great rivers discharge their waters into the sea.

But in proportion as a river, that has none of these obstacles in its bed, approaches towards its mouth, we see the velocity of its current augment, at the same time that the declivity of the bed diminishes. It is for this reason that inundations are more frequent and considerable, and do more damage in the interior parts of a country, than towards the mouths of most rivers.

In the Po, for example, the height of the banks made to keep in the waters, diminishes as the river approaches to the sea. At Ferrara, they are twenty feet high: whereas, nearer the sea, they do not exceed ten or twelve feet, although the channel of the river is not larger in the one place than in the other.

The mouths of rivers, by which they discharge their waters into the sea, are liable to great variations, which produce many changes in them.

1st. The velocity and direction of the current at these mouths are in a continual variation, caused by the tides, which alternately retard and accelerate the stream.

2dly. During the flowing of the tide, the current of the river is first stopped, then turned into a direction entirely contrary throughout a considerable extent: if we may believe M. de Buffon, there are rivers in which the effect of the tides is sensible at 150 or 200 leagues from the sea.

3dly. This state of things is a cause of a a great quantity of sand, mud, &c. being precipitated and accumulated in the channel near the mouth. This continually raises and widens the bed, and at last changes it entirely into a new place, or at least opens new mouths to discharge the waters at. The Rhine, the Danube, the Wolga, the Indus, the Ganges, the Nile, the Mississippi, and many other rivers, are instances of this.

4thly. All these effects are less sensible at the mouths of little rivers, as their currents oppose no sensible obstacle to the flowing of the tides; so that the ebb carries off again what the flow had brought in.

Whenever the course of a river throughout a considerable extent of country, approaches towards a right line, its current will have a very great rapidity; and the velocity wherewith it runs diminishing the effect of its natural gravitation, the middle of the current will rise up, and the surface of the river will form a convex curve of sufficient elevation to be perceived by the eye; the highest point of this curve is always directly above the line of greatest current in the stream.

On the contrary, when rivers approach near enough to their mouths for a sensible effect to be produced in them by the flowing of the tides; and also, when in other parts of their course they meet with obstacles at the sides of their channel; in both these cases the surface of the water at the sides of the current is higher than in the middle, even though the stream should be rapid. In this situation of things, the surface of the river forms a concave curve, the lowest point of which, or that of inflection, is directly over the line of greatest current. The reason of this is, that there are in this case two different and opposite currents in the river; that by which the waters flow towards the sea, and preserve their motion even to a considerable distance; and that of the waters which remount, either by the flowing of the tide, or by their meeting with local obstacles, which form a counter current.

An island in the middle of a river produces the same effect as obstacles at the sides, regard being had to the difference of situation of each.

Eddies and whirlpools in rivers, in the centre of which there appears a conical or spiral cavity, and about which the water turns with great rapidity and sucks in whatever approaches it, proceed in general from the mutual percussion of these two counter currents; and the vacuity in the middle is produced by the action of the centrifugal force, by which the water endeavours to recede, in a direct ratio of its velocity, from the centre about which it moves.

If rivers persevered always nearly in the same state, the best means of diminishing the velocity of the current when it is found too great for the purposes of navigation, would be by widening the channel; but as all rivers are subject to frequent increase and diminution, and consequently to very different degrees of velocity and force in the current, this method is liable to produce very detrimental effects; for, when the waters are low, if the channel is very large in proportion, the stream will excavate a particular bed, which, according to the irregularities of the bottom, will form various turnings and windings with regard to the principal bed; and, when the waters come to increase, they will follow, to a certain degree, the directions which the bottom waters take in this particular bed, and thereby will strike against the sides of the channel, so as to destroy the banks and cause great damages.

It would be possible to prevent in part the bad effects proceeding from the current striking against the banks, by opening, at those places where it strikes, little gulphs into the land, dug in such a form and direction as that the striking current should enter and circulate therein, so as to destroy, or at least, greatly diminish its velocity. This effect would be felt for a considerable way down the river.

This same method might probably be used with success against the destruction of bridges, weirs, &c. by the violence of the stream during floods. Such gulfs being dug into the outer side of those turnings in the river which are immediately above the place to be secured from the violence of the stream, would successively diminish its velocity, its force and dangerous effects, a considerable way down the river.

RIVINA, a genus of the monogynia order, in the tetrandria class of plants. The perianthus is four-leaved, coloured, and permanent, the leaflet oblong egged and obtuse; there is no corolla, unless the calyx is considered as such. There are four or eight filaments, shorter than the calyx, approaching by pairs, permanent; the antheræ are small. The germ is large and roundish; the style very short; the stigma simple and obtuse. The berry is globular, sitting on the green reflected calyx, one-celled with an incurved point. There is one seed, lensform, and rugged. There are four species. It grows naturally in most of the islands of the West Indies. The juice of the berries of the plant will stain paper and linen of a bright red colour, and many experiments made with it to colour flowers have succeeded extremely well in the following manner; the juice of the berries was pressed out, and mixed with common water, putting it into a phial, shaking it well together for some time, till the water was thoroughly tinged; then the flowers, which were white and just fully blown, were cut off, and their stalks placed into the phial; and in one night the flowers have been finely variegated with red; the flowers on which the experiments were made, were the tuberose and the double white narcissus.

RIX-DOLLAR, a silver-coin current in different parts of Europe. See Coin.

ROACH. See Cyprinus.

ROAD, in navigation, is a place of anchorage at some distance from shore, where vessels usually moor, to wait for a wind or tide proper to carry them into harbour, or to set sail. When the bottom is firm, clear of rocks and sheltered from the wind, it is called a good road; and when there is but little land on any side, it is termed an open road. The roads in his majesty's dominions are free to all merchant vessels, belonging to his subjects and allies. Captains and masters of ships who are forced by storms, &c. to cut their cables, and leave their anchors in the roads, are obliged to fix marks or buoys, on pain of forfeiting their anchors, &c. Masters of ships coming to moor in a road, must cast anchor at such a distance, as that the cables, &c. do not mix, on pain of answering the damages; and when there are several vessels in the same road, the outermost to the sea-ward is obliged to keep a light in his lanthorn in the night-time, to apprise vessels coming in from sea.

ROASTING. See Metallurgy.

ROB, in pharmacy, the juices of fruit purified and inspissated till it is of the consistence of honey.

ROBBERY, in law is a felonious taking away of another man's goods from his person or presence against his will, putting him in fear, and of purpose to steal the same. West. Symbol. To make a robbery there must be a felonious intention; and so it ought to be laid in the indictment. 1 H. H. 532. It is immaterial of what value the thing taken is; a penny, as well as a pound thus forcibly extorted, makes a robbery. 1 Haw. 34.

If a man forces another to part with his property, for the sake of preserving his character from the imputation of having been guilty of an unnatural crime, it will amount to a robbery, even though the party was under no apprehension of personal danger. Leach's Cro. Law, 257.

If any thing is snatched suddenly from the head, hand, or person of any one, without any struggle on the part of the owner, or without any evidence of force, or violence being exerted by the thief, it does not amount to robbery. But if any thing is broken or torn in consequence of the sudden seizure, it would be evidence of such force as would constitute a robbery: as where a part of a lady's hair was torn away, by snatching a diamond pin from her head, and an ear was torn by pulling off an ear-ring; each of these cases was determined to be a robbery. Leach's Cro. Law, 264.

By 7 G. II. c. 21, if any person shall, with any offensive weapon assault, or by menaces, or in any forcible or violent manner, demand any money or goods, with a felonious intent to rob another, he shall be guilty of felony, and be transported for seven years.

If any person being out of prison, shall commit any robbery, and afterwards discover any two persons guilty of robbery, he shall have the king's pardon.

The hundred in which a robbery on the highway is committed, is liable to pay the damage when it is committed between the rising and setting of the sun, in any day, except Sunday, in case the robbers are not taken in forty days; hue and cry being made after the robber. And he who apprehends and prosecutes a robber on the highway, so as to convict him, is entitled to receive of the sheriff of the county where the robbery was committed, the sum of forty pounds, with the horse, furniture, arms, &c. upon such person's producing a proper certificate from the judge before whom the robber was convicted.

ROBERGIA, a genus of the class and order decandria pentagynia. The cal. is five-parted; pet. five; drupe with one-seeded nut and two-valved shell. There is one species a shrub of Guiana.

ROBINIA, *false acacia*, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The calyx is quadrifid; the legumen gibbous and elongated. There are seventeen species. The most remarkable is the caragnana, the leaves of which are conjugated, and composed of a number of small folioles, of an oval figure, and ranged by pairs on one common stock. The flowers are leguminous, and are clustered on a filament. Every flower consists of a small bell-shaped petal, cut into four segments at the edge, the upper part being rather the widest. The keel is small, open, and rounded. The wings are large, oval, and a little raised. Within are ten stamina united at the base, curved towards the top; and rounded at the summit. In the midst of a sheath, formed by the filaments of the stamina, the pistil is perceivable, consisting of an oval germen, terminated by a kind of button. This germen becomes afterwards an oblong flattish curved pod, containing four or five seeds, of a size and shape irregular and unequal; yet in both respects somewhat resembling a lentil.

This tree grows naturally in the severe climates of Northern Asia, in a sandy soil mixed with black light earth. It is particularly found on the banks of great rivers, as the Oby, Jenisia, &c. It is very rarely met with in the inhabited parts of the country, because cattle are very fond of its leaves, and hogs of its roots; and it is so hardy, that the severest winters do not affect it. Gmelin found it in the neighbourhood of Tobolsk, buried under fifteen feet of snow and ice, yet had it not suffered the least damage. Its culture consists in being planted or sowed in a lightish sandy soil, which must on no account have been lately manured. It thrives best near a river, or on the edge of a brook or spring; but presently dies if planted in a marshy spot, where the water stagnates. If it is planted on a rich soil, well tilled, it will grow to the height of twenty feet, and in a very few years will be as big as a common birch tree.

In a very bad soil this tree degenerates, and becomes a mere shrub; the leaves grow hard, and their fine bright green colour is changed to a dull deep green. The Tongusian Tartars, and the inhabitants of the northern parts of Siberia are very fond of the fruit of this tree, it being almost the only sort of pulse they eat. The leaves and tender shoots of this tree make excellent fodder for several sorts of cattle. The roots being sweet and succulent, are very well adapted for fattening hogs; and the fruit is greedily eaten by all sorts of poultry. After several experiments somewhat similar to the methods used with anil and indigo, a fine blue colour was procured from its leaves. The smaller kind of this tree seems still better adapted to answer this purpose. The striking elegance of its foliage, joined to the pleasing yellow colour of its beautiful flowers, should, one would imagine, bring it into request for forming nosegays, or for speedily making an elegant hedge. Besides the qualities above recited, it possesses the uncommon advantage of growing exceedingly quick, and of being easily transplanted. There are large plantations of it now in Sweden, Norway, Lapland, and Iceland.

The robinia spinosa is a beautiful hardy shrub, and on account of its robust strong prickles, might be introduced into this country as a hedge plant, with much propriety. It resists the severest cold of the climate of St. Petersburgh, and perfects its seed there. It rises to the height of six or eight feet; does not send out suckers from the root, nor ramble so much as to be kept with difficulty within bounds. Its flowers are yellow, and the general colour of the plant a light pleasing green.

ROBINSONIA, a genus of the icosandria monogynia class and order. The cal. is five-toothed; pet. five; berry striated, two-celled; cells one-seeded; seeds villose. There is one species, a tree of Guiana.

ROCHFORTIA, a genus of the class and order pentandria digynia; the cal. is five-parted; cor. one-petalled, funnel-form, inferior; fruit two-celled, many-seeded. There are two species, shrubs of Jamaica.

ROCK-CRYSTAL. See QUARTZ.

ROCKET. See PYROTECHNY.

ROCKS are divided into five classes: namely, 1. Primitive rocks; 2. Rocks of transition; 3. Stratified, or secondary rocks; 4. Alluvial depositions; 5. Volcanic rocks.

Rocks primitive.

The rocks belonging to this class are distinguished from all others in containing no remains of organic bodies, and in being covered by the rocks of the other classes, but never themselves covering any other class of rocks. The term primitive was applied by Lehman, to whom we are indebted for the first scientific division of rocks, on the supposition that the rocks so denominated were formed before any other; and the term has been continued by Werner, because he has embraced the same hypothesis. The following table contains the different divisions of primitive rocks, arranged according to the order in which Werner thinks they were formed.

1. Granite,
2. Gneiss,
3. Micaceous shistus,
4. Argillaceous shistus,
5. Porphyry,
6. Sienite,
7. Serpentine,
8. Primitive limestone
9. Primitive trap,
10. Quartz,
11. Topasfels,
12. Kieselschiefer.

Let us take a view of each of these in order.

Granite is composed essentially of felspar, quartz, and mica, crystallized and united to each other. The size and proportion of the constituents vary exceedingly; but the felspar usually predominates, and the proportion of mica is smallest. Its texture is granular, and its hardness usually very considerable: hence it admits a fine polish, and is very beautiful and durable. Granite sometimes contains schorl accidentally mixed with it, and still more rarely garnets. Granite rocks are sometimes stratified, and sometimes not. They are very common, especially in great chains of mountains. Granite contains few ores. Those of iron and tin occur most frequently. See GRANITE and GNEISS.

Gneiss, like granite, is composed essentially of felspar, quartz, and mica; but they form plates which are laid on each other, and separated by thin layers of mica. The beds of gneiss sometimes alternate with layers of granular limestone, shistose, hornblende, and porphyry.

Micaceous shistus. This rock is composed essentially of quartz and mica, which alternate in plates. The mica is usually most abundant. It is grey or brown, and sometimes greenish. The texture of micaceous shistus is essentially shistose. Its stratification is very distinct. It very frequently contains garnets, and sometimes felspar, cyanite, granatite, and tourmalines. In mountains, beds of micaceous shistus often alternate with those of granular limestone and hornblende shistus, and sometimes with those of actinote, pyrites, galena, and other metallic bodies. Indeed almost all the metals are found in it either in beds or veins.

Argillaceous shistus. This rock is composed essentially of slate or argillaceous shistus; but it sometimes contains accidentally quartz, felspar, shorl, hornblende, and pyrites. It is always shistose; but the thickness of the layers varies considerably. The beds of this rock are often interrupted by subordinate beds of other minerals; the chief of these are chlorite-shistus, talc-shistus, zeichen-schiefer, alum-shistus. These frequently pass into argillaceous shistus. Sometimes also beds of granular limestone, hornblende, and some metallic ores, alternate with argillaceous shistus. This rock usually covers micaceous shistus.

Ores are common in this rock, but less so than in the two preceding. They are usually in veins.

Porphyry. The term porphyry is applied to all rocks consisting of a compact ground, in which distinct and separate crystals of some other substance are embedded. Werner confines it to certain primitive rocks which belong to a particular formation. These, considered relative to their ground, are divided into five species, each of which is denominated from its ground.

1. Hornstone porphyry. The hornstone is sometimes conchoidal, sometimes splintery,

and of a red or green colour. The crystals are quartz and felspar.

2. Felspar porphyry. The ground is usually red. The crystals are felspar and quartz.

3. Sienite porphyry. The ground is a mixture of felspar and hornblende. The crystals are felspar and quartz.

4. Pitchstone porphyry. The ground is red or green, sometimes brown, and even black.

5. Clay porphyry. The ground is an indurated clay, commonly reddish, which sometimes passes into splintery hornstone. The crystals are felspar and quartz; sometimes it contains hornblende, and more rarely mica.

Porphyry mountains are not stratified, and contain no beds of foreign substances. They are not rich in ores, yet frequently contain veins worth working.

Sienite. This rock is composed essentially of crystals of felspar and hornblende, immediately and intimately united. The felspar usually predominates. When the felspar is compact, the rock assumes a porphyritic structure. It sometimes contains accidentally grains of quartz and mica, but in a very small proportion. Its texture is granular, rarely shistose. Seldom stratified. Does not contain foreign beds. It sometimes contains metallic veins. It usually covers porphyry.

Serpentine. This rock is essentially simple. Sometimes it contains accidentally talc, asbestus, and steatites; and sometimes mica, garnets, and granular limestone, magnetic ironstone, arsenical pyrites, &c. Serpentine rocks are not stratified. Seldom contain beds of foreign minerals. They contain few ores, and seldom any worth working.

Primitive limestone. This rock is essentially simple: its mass is granular limestone of a greyish white colour. Sometimes it is accidentally mixed with mica, quartz, hornblende, tremolite, actinote, asbestus, talc, &c. Its texture granular, the grains have a foliated texture, and a crystallized appearance. This rock sometimes contains metallic veins; chiefly of galena, magnetic ironstone, blende, and pyrites.

Primitive traps. The word trap is Swedish, and signifies a stair. It was applied by the Swedish mineralogists to certain rocks whose strata when exposed, the one jutting out under the other, gave an appearance somewhat like a stair. The term was adopted by other nations, and was applied indiscriminately to a great variety of rocks; which yet bore a certain resemblance to each other. This generalization, however, introduced much confusion into the subject, which was first cleared up by Werner and his disciples. Under the term traps Werner comprehends certain series of rocks, distinguished chiefly by the hornblende, which they all contain. In the most antient, the hornblende is almost pure; this purity gradually diminishes, and in the most recent traps the hornblende degenerates to a kind of indurated clay. There are, then, three formations of traps; 1. Primitive traps; 2. Transition traps; 3. Secondary traps. The first only occupy our attention at present.

The primitive traps are composed almost entirely of hornblende. It is sometimes mixed with felspar, more rarely with mica and pyrites. There are four species; 1. Common hornblende; 2. Shistose hornblende; 3. Primitive grunstein; 4. Shistose grunstein.

1. Common hornblende is a simple rock. Its grains are sometimes so small that it appears compact. Sometimes it contains mica.

2. Shistose hornblende occasionally contains quartz, actinote, and pyrites.

3. Primitive grunstein is a mixture of hornblende and felspar. It is divided into different varieties, according as its texture is granular or compact. 1st. Common grunstein, in which the hornblende and felspar are intimately united. It resembles a sienite, in which the hornblende predominates. 2d. Fine grained grunstein, in which are embedded crystals of felspar. Texture at once granular and porphyritic. 3d. When the grains become very fine, the grunstein becomes porphyritic. 4th. When the mass becomes entirely homogeneous, we have the green porphyry of the antients.

4. Shistose grunstein is a rock composed of compact felspar, hornblende, and a little mica; sometimes it contains also quartz. Its texture is shistose. The hornblende and felspar occur nearly in equal proportion.

Grunstein often contains metallic veins.

Quartz. Considerable rocks occur composed entirely of quartz. Sometimes, indeed, they contain accidentally mica, felspar, tin, pyrites. The texture of these rocks is usually compact, but sometimes shistose.

Topasfels. This rock is composed of quartz, shorl, topaz, and lithomarga. The first three ingredients alternate in thin beds. Its texture is granular; its structure shistose. Very rare. It has been found only in Saxony, near Awerbach, forming a mountain called Schneckenstein. It rests upon granite, and contains no ores.

Kieselchiefer. Kieselchiefer, or siliceous shistus, often forms considerable rocks. Their texture is compact. They are often traversed by small veins of quartz. They contain no metallic substance.

Rocks of transition.

The rocks belonging to this class agree with those of the first in containing no remains of organized beings, or at least but seldom; but they have a considerable resemblance to those of the third class. Werner considers them as forming the passage between the first and third class of rocks; hence their name. The following table contains a list of the transition rocks.

1. Transition limestone,
2. Grauwacke,
3. Transition traps.

Let us take a view of each of these in order.

Transition limestone. This rock is simple. Its mass is a limestone; sometimes granular, sometimes compact, according as its age approaches to primitive or secondary limestone. Fracture is somewhat splintery. Somewhat transparent. Its colours are variously mingled; often red or black with white veins. Seldom contains foreign substances. Sometimes shells are observed in its superior strata.

Sometimes it alternates with beds of argillaceous shistus, and sometimes with beds of mandelstein, as in Derbyshire. It usually covers argillaceous shistus. Seldom rises to any considerable height. Usually stratified. Strata very thick. Often contains metallic veins.

Grauwacke. There are two species of rocks of grauwacke, common and shistose.

Common grauwacke is a sandstone composed of grains of quartz, kieselchiefer, and argillaceous shistus agglutinated by a cement of clay. The grains are sometimes very small, sometimes as large as a hazel nut.

Shistose grauwacke is a simple shistose rock, which has a strong resemblance to argillaceous shistus, but differing in its position. It forms beds which alternate with common grauwacke.

Grauwacke rocks are traversed by veins of quartz. They contain sometimes shells and reeds petrified. They contain no foreign beds. These rocks are distinctly stratified. The strata do not run parallel to those of the other rocks on which they lie. They usually cover transition limestone, and do not rise to any great height. They are rich in ores.

Transition traps. The principal base of all the rocks belonging to this formation is grunstein. This constitutes many of the primitive traps; but in the transition traps, the mixture is much more intimate, the grain is much finer, and the mass much more homogeneous, and its constituents are more or less blended together. Transition traps consist principally of two species, mandelstein and globular trap.

1. Mandelstein or amygdaloid. By this term is implied all rocks composed of a compact ground, containing imbedded in it minerals of a round or almond form, or containing cavities of that form. They are distinguished into primitive, transition, and secondary mandelsteins. Transition mandelstein consists of a ground of shistose hornblende, decomposed and resembling wacken or ferruginous clay. The cavities are sometimes empty, sometimes full, and then they contain quartz and chalcedony. The toadstone of Derbyshire is referred to this species. It contains round masses of calcareous spar.

2. Globular trap. This is a shistose grunstein, partly decomposed and reduced to the state of a fine grained wacken. It is composed of large spherical bodies, consisting of concentric layers; the central part being hardest.

Transition traps are not stratified. They form separate conical mountains, usually near those of transition limestone. They contain some metallic veins of copper, iron, tin, &c.

CLASS III.

Rocks secondary.

These rocks are distinguished by the remains of organized bodies, which they contain abundantly. They are usually stratified. The following table contains a list of these different rocks, arranged according to the supposed time of their formation.

1. Sandstone,	5. Rock salt,
2. Secondary limestone,	6. Pit coal,
3. Chalk,	7. Eisenthon,
4. Gypsum,	8. Secondary traps.

Sandstone. This rock is composed of quartz, varying in size; sometimes also grains of kieselschiefer, and very rarely of felspar. These grains are cemented together, sometimes by means of clay, sometimes of marl or lime, and sometimes of quartz. The cement varies in quantity, but never predominates. The size of the grains varies much: when large, the rock is usually called pudding stone.

This rock is very distinctly stratified. The beds of it often alternate with beds of compact limestone, pit coal, oolite, and a species of sandstone shistus fine grained, and mixed with leaves of mica, which gives it the appearance of micaceous shistus. It contains few metallic ores of value. Sometimes cobalt is found in it.

Secondary limestone. This rock is simple, and composed of compact limestone. Occasionally it contains crystals of quartz, pyrites, &c. Shells occur very frequently in it. It is very distinctly stratified. Its beds are sometimes separated by beds of shistose bituminous marl and sandstone, and by tubercles of hornstone and flint often arranged in beds. It is often traversed by metallic veins, chiefly of galena, grey copper ore, malachite, &c.

Chalk. The strata of chalk may be considered perhaps as subordinate to those of secondary limestone. They consist entirely of chalk, sometimes interrupted by thin beds of flint in tubercles. Shells often occur converted into siliceous matter, and sometimes pyrites in spherical masses. No metallic ores ever occur in them.

Gypsum. The strata of gypsum usually occur in mountains alternating with those of sandstone, limestone, marl, clay, rock salt. They often contain foreign crystals; chiefly quartz, arragonite, boracite, garnet: sometimes they contain sulphur. Few petrefactions are found in them except the bones of quadrupeds. They contain scarcely any metallic ores. See SULPHAT OF LIME.

Rock salt. The mountains which contain strata of rock salt are to be referred to a particular formation of gypsum, with which they usually alternate. They contain no ores.

Pit coal is found in two different formations. The first of these is distinguished particularly by the name of coal formation, or mountains of coal. They are usually composed of beds of, 1. Very brittle sandstone, containing often small particles of mica; 2 Another sandstone or pudding stone of very large grains: 3. Shistose clay; 4. Marl; 5. Limestone; 6. An argillaceous porphyry distinguished by the name of secondary porphyry; 7. Ferruginous clay; 8. Coal. The beds of coal vary in thickness and in number.

This formation of coal occupies countries of no great elevation. They occur chiefly at the bottom of chains, and in the intermediate valleys. The strata of coal in the north of England belong to it.

Coal is found in other situations, especially in the secondary trap formation. Those of Scotland belong to this class.

Argillaceous ironstone. The beds of this mineral usually alternate with those of indurated clay, shistose clay, marl, brandschiefer, and sandstone. They frequently contain calamine mixed with galena. The impressions of plants and marine petrefactions are often observable in them. They usually form small insulated hills, and are not very common.

Secondary traps. The mountains of secondary traps are composed of various rocks; some of which belong exclusively to this formation; others are found also in other mountains. The rocks peculiar to secondary traps are, 1. Basalt; 2. Wacken; 3. Basaltic tufa; 4. Secondary mandlestein; 5. Porphyry shistus; 6. Graustein; and, 7. Secondary grunstein.

1. Basalt, considered as the mass of a mountain, is a rock more or less compound; usually it is of a porphyritic structure, has for its ground the mineral called basalt. It contains usually grains of olivine, augite, basaltic hornblende, magnetic ironstone, and sometimes leucite, felspar, quartz, &c.; sometimes also mica, actinote, chalcedony. Sometimes it assumes the structure of mandelstein. In that case its cavities are filled with zeolite, steatites, limestone, &c.

It usually appears in large separate masses often prismatic. It is very common often forming detached mountains.

2. Wacken sometimes forms beds in the secondary traps. It is usually between clay and basalt. It neither contains olivine nor augite, but crystals of basaltic hornblende, and above all of black hexahedral mica. This last substance distinguishes wacken from basalt, which very seldom contains it.

3. Basaltic tufa results from the decomposition of certain basalts. It consists of fragments of basalt, pieces of olivine, the remains of vegetables, &c. agglutinated by a cement of clay.

4. The amygdaloids or mandelsteins of the secondary traps have for their base a clay which seems to be a decomposed grunstein, often penetrated with siliceous matter. It has a good deal of resemblance to wacken, and sometimes passes into it: at other times it assumes a more compact texture, and passes into basalt. Its cavities are sometimes empty, sometimes filled with green earth, zeolite, limestone, &c.

5. Porphyry shistus is a rock whose structure is shistose, and its texture porphyritic. Its base is klingstein, containing grains of felspar and sometimes of hornblende. It has a good deal of resemblance to basalt, and often passes into it But it is more nearly a chemical compound, being more transparent, sonorous, and hard.

6. Graustein is a rock composed of small grains of felspar and hornblende, which graduate into each other and form a mass almost homogeneous of an ash grey colour. It contains olivine and augite.

7. Secondary grunstein, like the primitive and transition, is composed of hornblende and felspar; but its grains are less perfectly crystallised, and less intimately mixed. It usually covers rocks of basalt.

Such are the rocks peculiar to the secondary traps. They have all less or more of a crystallized structure; whereas the other minerals found in secondary traps, but not peculiar to them, are mechanical depositions. Wacken and basalt form the passage from the one to the other. The mechanical depositions, sand, clay, &c. are usually lowermost; they are covered by wacken. Some of the other substances always occupy the summits.

Trap mountains contain abundance of petrefactions, but no ores except some veins and grains of iron. They are usually insulated; very seldom forming chains. The mountains of basalt and porphyry shistus are usually conical. They are hardly ever covered by other rocks. They usually cover sandstone, coal, secondary limestone, shistose clay; and veins of them are not uncommon in primitive mountains.

CLASS V.

Rocks volcanic.

This name is given to all the minerals thrown out during volcanic eruptions. The most complete account of them has been given by Dolomieu, who devoted the greatest part of his life to the study of volcanoes. Part of his division was published by him in the Journal de Physique for 1794; and an abstract of the whole has been given by Brochant from notes taken during a course of geology given by Dolomieu in 1797. Volcanic products have been divided by this celebrated geologist into five classes: 1. Minerals modified by the fire of volcanoes; 2. Substances not modified by the fire, or thrown out unaltered; 3. Substances sublimed by the fire of volcanoes; 4. Minerals altered by the sulphurous acid vapours of volcanoes; 5. Volcanic minerals altered by the action of the atmosphere.

Minerals modified by the fire. This set of minerals is subdivided into two heads. The first comprehends those minerals which, though they have been modified by fire, yet exhibit no appearance of its action. The second consists of those which retain obvious marks of the action of fire. Those of the first head have been distinguished by the name of compact lavas; those of the second by the name of porous.

Compact lavas bear so close a resemblance to certain rocks of an origin not volcanic, that it is extremely difficult to distinguish them. Some have the appearance of basalt; others of granite, porphyry, and various secondary traps. Dolomieu divides them into four species according to their base.

1. Compact lavas with an argillo-ferruginous base. Their colour is usually black. Fracture imperfectly conchoidal. Texture very compact. Sonorous. Smell argillaceous. Attract the magnetic needle. Very common in volcanic countries. Frequently contain crystals of augite, felspar, hornblende, garnet, leucite, olivine, mica. A specimen of the lava of Catania in Sicily, analysed by Dr. Kennedy, contained,

51.0 silica,
19.0 alumina,
14.5 oxide of iron,
9.5 lime,
4.0 soda,
1.0 muriatic acid,
———
99.0.

A specimen of the lava of Sta. Venere in Sicily he found to contain

55.78 silica,
17.50 alumina,
14.25 oxide of iron
10.00 lime,
4.00 soda,
1.00 muriatic acid,
———
97.5.

Compact lava with a petrosiliceous base. Colour very variable, grey, black, and white; but all become white before the blow-pipe. Fracture conchoidal. Grain fine and compact. Smell slightly argillaceous. Does not affect the magnetic needle. Contains usually grains of felspar; sometimes of hornblende, mica: Lucites are uncommon in it:

Compact lavas with a granite base. So named because they resemble granite, and contain all its constituents. The felspar usually predominates. It is in lamellar masses, seldom in crystals. This species contains crystals of hornblende, mica, augite.

Compact lavas with a leucite base. These lavas are uncommon. No current of lava has ever been observed composed entirely of them. They occur near Vesuvius. In them the leucites are so abundant and compressed, that they assume a compact appearance. They sometimes contain crystals of hornblende, augite, mica.

Compact lavas like basalt often affect a prismatic form.

Porous lavas, &c. This second head consists according to Dolomieu, of minerals having the same base with compact lavas; but these bases have undergone certain modifications, in which the action of fire has become evident. These modifications are chiefly three; swelling, vitrification, and calcination. The minerals belonging to this head may be reduced to seven species.

1. Porous lavas. The lavas on the surface of currents usually assume this form; especially the surface of the argillo-ferruginous lavas. The cavities are usually spheric in them, while in the porous lavas, formed from the other compact lavas, the cavities are commonly elongated. They are often employed as millstones and in buildings.

2. Scorias. The substances distinguished by this name have more or less resemblance to metallic scorias. To them may be referred the substance called black pouzzolano. It has been produced by scorification, though it no longer retains the characters of it.

The term pouzzolano (derived from the city Pouzzoles), has been usually applied to earthy matters ejected by volcanoes, which make an excellent mortar with lime. See PUZZOLANA. The best is found always in the antient currents; that in the modern forms bad mortar. There are three sorts of pouzzolano; the black, which is a scoria altered: the white, which is composed of pumice; and the red, which belongs to the products of calcination.

Compact glasses. Volcanic vitrifications are uncommon, especially compact glasses. They all resemble common glass. They are more or less transparent, often black, sometimes blueish or greenish, very seldom colourless. Sometimes prismatic.

Porous glasses or pumice stones. When the compact glasses are exposed to the heat of our furnaces, they emit a great number of air-bubbles, which renders them porous. Such is the origin of pumice. It has the same base as compact glass. The texture of pumice stones is fibrous; the fibres have a silky lustre. Colours various; white, brown, yellow, black. But before the blow-pipe they all melt into a white enamel. White pouzzolano is composed of the detritus of these stones. A specimen of pumice stone analysed by Klaproth, yielded

77.50 silica,
17.50 alumina,
1.75 oxide of iron,
3.00 soda of potass,

99.75.

Nearly the same result had been previously obtained by Dr. Kennedy.

Volcanic sands and ashes. The sands are composed of grains varying in size. They are usually mixed with crystals of felspar, augite, magnetic ironstone, &c. and often cover a great extent of ground. Etna has covered the country for 50 leagues round it with a bed of sand twelve feet thick. Volcanic ashes are merely very fine sand. They are so light, that during the eruptions of Etna, the wind often transports them as far as Egypt.

Agglutinated matters. These are merely sands and ashes covered and cemented together by a torrent of melted lava.

Calcined substances. All stony bodies which have undergone a kind of calcination by volcanic fires are denoted by this name. All volcanic matters often undergo this change. Their grain is rendered more harsh, and their feel more dry. The ferruginous lavas become more red, and cease to be attracted by the magnet.

Minerals not modified by the fire. These matters existed in the mountain before the commencement of volcanic fire, and are thrown out by it unaltered. The study of them is important, because they inform us of the internal structure of volcanic mountains. They usually belong to the primitive rocks. Sometimes they are fragments of rocks, and sometimes groups of crystals. They are thrown out in general at the beginning of eruptions.

Volcanoes sometimes emit torrents of muddy water. From these have originated the minerals called volcanic tufas. Their colour is various.

Substances sublimed. An immense quantity of matter is exhaled by volcanoes; partly in the state of gas or steam, partly in a visible form.

Hydrogen gas, carbonic acid, sulphurous acid, muriatic acid, nitric acid, &c. have been detected issuing from them.

The mineral substances which are sublimed from them, and which afterwards are deposited on their sides, are sulphur, which is very abundant; mineral oil, and various salts, especially muriats of ammonia, soda, copper, and iron; sulphats of alumina, soda, iron, and copper, and carbonat of soda. Metallic bodies are also found among these substances, iron, copper, antimony, arsenic, cinnabar, &c.

Substances altered by sulphurous acid vapours. The sulphur volatilized by volcanoes is often converted into an acid, which, acting upon the lavas, changes their appearance considerably. They become of a yellowish-white colour, much lighter and dryer, and are more easily pulverized. They contain an unusual proportion of silica, because the sulphurous acid has combined with the alumina, and formed a salt afterwards washed away by the rain. The same vapours often attack stony matters not volcanic.

The principal products of the action of these vapours on lavas are alum and sulphats of lime, magnesia and iron. These salts, especially the first, are collected with great advantage.

Volcanic substances altered by the action of the atmosphere. All rocks undergo greater or smaller changes when long exposed to the atmosphere; but these changes are much greater and more rapid in volcanic rocks than in others. Sometimes, however, it is very slow. Hence the age of volcanoes cannot be determined by the state of volcanic eruptions.

The argillo-ferruginous lavas become first red; the petrosiliceous become of a dirty grey. By degrees they assume an earthy appearance, and pass at last to a kind of friable clay. The scorias undergo the same changes much more rapidly. The earthy matters produced by this decomposition are afterwards washed down by the waters, and form large beds, which constitute a very fertile soil. The porous lavas are often partly filled with earth washed down by rains from decomposed lavas. Dolomieu supposed many crystals to owe their existence to the infiltrations of such waters.

Besides the real products of volcanoes, there are rocks which have been more or less altered by the action of fires not volcanic. These fires have often originated from the combustion of strata of coal. These have been called pseudo-volcanic rocks. These rocks are four in number; namely, porcelain jasper, burnt clay, earthy scorias, and a particular variety of polierschiefer.

Porcelain jasper is considered as a shistose clay, which has been calcined. Burnt clay resembles brick: It has been exposed to a weaker fire than porcelain jasper. Like that mineral it is considered as having been originally a shistose clay. Earthy scorias are light porous substances like scorias. They appear to have been melted. They are usually near burnt coal strata. A variety of polierschiefer sometimes occurs, which appears to have been a clay exposed to a moderate degree of heat, and rather dried than calcined. To these pseudo-volcanic minerals may be added the vitrified sorts, not uncommon in the highlands of Scotland. They seem to have originated from artificial fires. See GEOLOGY, MOUNTAINS, MINERALOGY, &c.

ROD, a land measure of sixteen feet and a half: the same with perch and pole.

ROD, in gauging. See GAUGING.

ROE, the spawn or seed of fish. That of male fishes is usually distinguished by the name of soft-roe, or milt, and that of the female, by hard-roe, or spawn.

So inconceivably numerous are these ovula, or small eggs, that M. Petit found 342,144 of them in a carp of eighteen inches; but Mr. Leewenhoeck found in a carp no more than 211,629. This last gentleman observes, that there are four times this number in a cod, and that a common one contains 9,344,000 eggs.

ROELLA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the twenty-ninth order, campanaceæ. The corolla is funnel-shaped, with its bottom shut up by staminiferous valvules; the stigma is bifid; the capsule bilocular, and cylindrical inferior. There are five species, shrubby plants of the Cape.

ROGUE, in law. See VAGRANT.

RHORIA, a genus of the class and order triandria monogynia: the cal. is bell-shaped, five-petalled, unequal; stigmas three, revolute; caps. There is one species, a shrub of Guiana.

ROLANDRA, a genus of the class and order syngenesia polygamia superflua. The florets are bundled in a head with scales interposed; cal. partial, two-valved, one-flowered: corollets hermaph. There is one species, a shrub of the West Indies.

ROLL, in manufactories, something wound and folded up in a cylindrical form.

Few stuffs are made up in rolls, except sattins, gawses, and crapes, which are apt to break, and take plaits not easy to be got out, if folded otherwise. Ribbons, laces, galloons, and paduas of all kinds, are also thus rolled.

A roll of tobacco is tobacco in the leaf, twisted on the mill, and wound twist over twist, about a stick or roller. A great deal of tobacco is sold in America in rolls of various weights; and it is not till its arrival in England, Spain, France, and Holland, that it is cut. A roll of parchment properly denotes the quantity of sixty skins.

The antients made all their books up in the form of rolls, and in Cicero's time the libraries consisted wholly of such rolls.

Roll, in law, signifies a schedule or parchment which may be rolled up by the hand into the form of a pipe.

In these schedules of parchment all the pleadings, memorials, and acts of court, are entered and filed by the proper officer; which being done, they become records of the court. Of these there are in the exchequer several kinds, as the great wardrobe-roll, the cofferer's-roll, the subsidy-roll, &c.

Roll is also used for a list of the names of persons of the same condition, or of those who have entered into the same engagement. Thus a court-roll of a manor, is that in which the names, rents, and services of each tenant are copied and inrolled.

Roll *muster*, that in which are entered the soldiers of every troop, company, regiment, &c.

As soon as a soldier's name is written down on the roll, it is death for him to desert.

Rolls-office, is an office in Chancery-lane, London, appointed for the custody of the rolls and records in chancery.

Rolls *of parliament*, are the manuscript registers, or rolls of the proceedings of our antient parliaments, which before the invention of printing, were all engrossed on parchment, and proclaimed openly in every county. In these rolls are also contained a great many decisions of difficult points of law, which were frequently in former times referred to the decision of that high court.

Roll, or Roller, is also a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines, and in several works and manufactures.

A rolling-mill shewn in fig. 4. Plate, consists of two iron rollers AB, mounted in a strong iron frame, which consists of two distinct parts DE, both firmly fixed to the iron floor F; each part has a long mortice through it, in the bottom of which is the brass socket for the pivot of the roller A, and in the upper part is the brass of the upper roller; this last brass is fixed to a piece of iron G, fig. 5, which slides up and down in the mortice, and is prevented from raising by the end of a strong screw *a*, screwed through the upper part of the frame D; the roller is prevented from falling by its own weight, by the brass *b* in the under side of the pivot, which is attached by two screw-bolts *d d* to a collar upon the screw *a*, so that when the screws are turned by a handspike put between the teeth of the wheel H, the rollers A and B may be brought nearer together or further off, as occasion requires. I is a stout iron bar, fixed between the frames DE by a wedge *i* at each end, so that its upper surface is level with the top of the lower roller; at a small distance above this, is another bar *k*, fixed by two screws, between these are laid several blocks of iron L, so as to fill up all the space, except a small opening, through which the bar to be flatted is introduced; P is a small trough of iron plate, bored full of holes, to which, water is brought by a small pipe *p*. The upper roller is put in motion by a strong shaft R, which conveys the power from a water-wheel, steam engine, &c.; and the lower one is moved by a cog-wheel S, on the shaft R, which turns another T, on the axis of the lower roller. The machine is placed near to a furnace, where the iron bars to be rolled, are heated to a welding heat; the mill is then put in motion, and the iron bars taken out, with a pair of pinchers, and their ends put through the opening between the bars K and L, between the rollers; which as they turn round squeeze the iron flat, and to the proper thickness throughout, while other men behind the machine, convey it away. The rollers can be set nearer or further off by turning the screws *a a* as before described. The rolling-mill is principally used for making hoops for barrels, and iron plates; the water brought by the pipe *p* is to prevent the roller from being heated by the iron.

ROLLER, in surgery, a long and broad bandage, usually of linen-cloth, rolled round any part of the body, to keep it in, or dispose it to a state of health.

RONDELETIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is funnel-shaped; the capsule bilocular, inferior, and polyspermous, roundish, and crowned. There are 14 species, shrubs of the West Indies.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOF. See Architecture.

ROOK, in ornithology. See Corvus.

ROOT. See Plants, *physiology of*.

Root, in mathematics, a quantity considered as the basis or foundation of a higher power; or one which being multiplied into itself any number of times, produces a square, cubic, biquadratic, &c. quantity; called the second, third, fourth, &c. power of the root, or quantity, so multiplied into itself; thus a is the square root of $a \times a$, or a^2; and 4 the square root of $4 \times 4 = 16$. Again, a is the cube-root of $a \times a \times a = a^3$; and 3 the cube-root of $3 \times 3 \times 3 = 27$: and so on. See Algebra.

The roots of powers are expressed by placing the radical sign $\sqrt{}$ over them, with a number denoting what kind of root they are: thus the square or second root of 16 is expressed by $\sqrt[2]{16}$, and the cube or third root of 27 by $\sqrt[3]{27}$; and, in general, the nth root of a raised to the power m, is expressed by $\sqrt[n]{a^m}$. When the root of a compound quantity is wanted, the vinculum of the radical sign must be drawn over the whole: thus the square root of $a^2 + 2ab + b^2$ is expressed by $\sqrt[2]{a^2 + 2ab + b^2}$; and it ought to be observed, that when the radical sign has no number above it, to denote what root is wanted, the square root is always meant; as $\sqrt{a^2}$, or $\sqrt{16}$, is the square root of a^2, or the square root of 16.

ROPE, hemp, hair, &c. spun into a thick yarn, and then several strings of this yarn twisted together by means of a wheel. When made very small it is called a cord, and when very thick, a cable. All the different kinds of this manufacture, from a fishing-line or whip-cord to the cable of a first-rate ship of war, go by the general name of cordage.

Ropes are made of every substance that is sufficiently fibrous, flexible, and tenacious, but chiefly of the inner barks of plants. The Chinese and other orientals even make them of the ligneous parts of several plants, such as certain bamboos and reeds, the stems of the aloes, the fibrous covering of the cocoa-nut, the filaments of the cotton pod, and the leaves of some grasses, such as the sparte (lygeum, Linn.). The aloe (agave, Linn.) and the sparte exceed all others in strength. But the barks of plants are the most productive of fibrous matter fit for this manufacture. Those of the linden tree (tilia) of the willow, the bramble, the nettle, are frequently used; but hemp and flax are the best; and of these the hemp is preferred, and employed in all cordage exceeding the size of a line, and even in many of this denomination.

Hemp is very various in its useful qualities; the best in Europe comes to us through Riga, to which port it is brought from very distant places southward. It is known by the name of riga rein (that is, clean) hemp. Its fibre is not the longest (at least in the dressed state in which we get it) but it is the finest, most flexible, and strongest. The next to this is supposed to be the Petersburgh braak hemp. Other hemps are esteemed nearly in the following order: Riga outshot, Petersburg outshot, hemp from Koningsburgh, Archangel, Sweden, Memel. Chucking is a name given to a hemp that comes from various places, long in the fibre, but coarse and harsh, and its strength is inferior to hemps which appear weaker. Its texture is such, that it does not admit splitting with the hatchel, so as to be more completely dressed: it is therefore kept in its coarse form, and used for inferior cordage. It is, however, a good and strong hemp, but will not make fine work. There are doubtless many good hemps in the southern parts of Europe; but little of them is brought to our market. Codilla, half clean, &c. are portions of the above-mentioned hemps, separated by the dressing, and may be considered as broken fibres of those hemps.

Only the first qualities are manufactured for the rigging of the royal navy and for the ships of the East India company.

ROPE-MAKING, is an art of very great importance; and there are few that better deserve the attention of the intelligent observer. Hardly any art can be carried on without the assistance of the rope-maker. Cordage makes the very sinews and muscles of a ship; and every improvement which can be made in its preparation, either in respect to strength or pliableness, must be of immense service to the mariner, and to the commerce and the defence of nations.

The aim of the rope-maker is to unite the strength of a great number of fibres. This would be done in the completest manner by laying the fibres parallel to each other, and fastening the bundle at the two ends; but this would be of very limited use, because the fibres are short, not exceeding three feet and a half at an average. They must therefore be entangled together, in such a manner, that the strength of a fibre shall not be able to draw it out from among the rest of the bundle. This is done by twisting or twining them together, which causes them mutually to compress each other. When the fibres are so disposed in a long skain, that their ends succeed each other along its length, without many of them meeting in one place; and this skain is twisted round; we may cause them to compress each other to any degree we please; and the friction on a fibre which we attempt to pull out may be more than its cohesion can overcome. It will therefore break. Consequently, if we pull at this twisted skain, we shall not separate it by drawing one parcel out from among the rest, but the whole fibres will break; and if the distribution of the fibres has been very equable, the skain will be nearly of the same strength in every part. If there is any part where many ends of fibres meet, the skain will break in that part.

We know very well that we can twist a skain of fibres so very hard, that it will break with any attempt to twist it harder. In this state all the fibres are already strained to the utmost of their strength. Such a skain of fibres can have no strength. It cannot carry a weight, because each fibre is already strained in the same manner as if loaded with as much weight as it is able to bear. What we have said of this extreme case is true in a certain extent of every degree of twist that we give the fibres. Whatever force is actually exerted by a twisted fibre, in order that it may sufficiently compress the rest to hinder them from being drawn out, must be considered as a weight hanging on that fibre, and must be deducted from its absolute strength of cohesion, before we can estimate the strength of the skain. The strength of the skain is the remainder of the absolute strength of the fibres, after we have deduced the force employed in twisting them together. From this observation may be established a fundamental principle in rope-making, that all twisting, beyond what is necessary for preventing the fibres from being drawn out without breaking, diminishes the strength of the cordage, and should be avoided when in our power.

It is necessary then to twist the fibres of hemp together, in order to make a rope; but we should make a very bad rope if we contented ourselves with twisting together a bunch of hemp sufficiently large to withstand the strains to which the rope is to be exposed. As soon as we let it go out of our hands, it would untwist itself, and be again a loose bundle of hemp; for the fibres are strained, and they are in a considerable degree elastic; they contract again, and thus untwist the rope or skain. It is necessary to contrive the twist in such a manner, that the tendency to untwist in one part may act against the same tendency in another and balance it. The process, therefore, of rope-making is more complicated.

The first part of this process is spinning of rope-yarns, that is, twisting the hemp in the first instance. This is done in various ways, and with different machinery, according to the nature of the intended cordage. We shall confine our description to the manufacture of the larger kinds, such as are used for the standing and running rigging of ships.

An alley or walk is inclosed for the purpose, about 200 fathoms long, and of a breadth suited to the extent of the manufacture. It is sometimes covered above. At the upper end of this rope-walk is set up the spinning-wheel, of a form resembling that in Plate Miscel. fig. 210. The band of this wheel goes over several rollers called whirls, turning on pivots in brass holes. The pivots at one end come through the frame, and terminate in little hooks. The wheel being turned by a winch, gives motion in one direction to all those whirls. The spinner has a bundle of dressed hemp round his waist, with the two ends meeting before him. The hemp is laid in this bundle in the same way that women spread the flax on the distaff. There is great variety in this; but the general aim is to lay the fibres in such a manner, that as long as the bundle lasts there may be an equal number of the ends at the extremity, and that a fibre may never offer itself double or in a bight. The spinner draws out a proper number of fibres, twists them with his fingers, and having got a sufficient length detached, he fixes it to the hook of a whirl. The wheel is now turned, and the skain is twisted, becoming what is called a rope-yarn, and the spinner walks backwards down the rope-walk. The part already twisted draws along with it more fibres out of the bundle. The spinner aids this with his fingers, supplying hemp in due proportion as he walks away from the wheel, and taking care that the fibres come in equally from both sides of his bundle, and that they enter always with their ends, and not by the middle, which would double them. He should also endeavour to enter every fibre at the heart of the yarn. This will cause all the fibres to mix equally in making it up, and will make the work smooth, because one end of each fibre is by this means buried among the rest, and the other end only lies outward; and this, in passing through the grasp of the spinner, who presses it tight with his thumb and palm, is also made to lie smooth. The greatest fault that can be committed in spinning is to allow a small thread to be twisted off from one side of the hemp, and then to cover this with hemp supplied from the other side; for it is evident, that the fibres of the central thread make very long spirals, and the skin of fibres which covers them must be much more oblique. This covering has but little connection with what is below it, and will easily be detached. But even while it remains, the yarn cannot be strong, for on pulling it, the middle part, which lies the straightest, must bear all the strain, while the outer fibres that are lying obliquely, are only drawn a little more parallel to the axis. This defect will always happen if the hemp is supplied in a considerable body to a yarn that is then spinning small. Into whatever part of the yarn it is made to enter, it becomes a sort of loosely connected wrapper. Such a yarn, when untwisted a little, will have the appearance of fig. 211. while a good yarn looks like fig. 212. A good spinner therefore endeavours always to supply the hemp in the form of a thin flat skain with his left hand, while his right is employed in grasping firmly the yarn that is twining off, and in holding it tight from the whirl, that it may not run into loops or kinks.

It is evident, that both the arrangement of the fibres and the degree of twisting depend on the skill and dexterity of the spinner, and that he must be instructed, not by a book, but by a master. The degree of twist depends on the rate of the wheel's motion, combined with the retrograde walk of the spinner.

We may suppose him arrived at the lower end of the walk, or as far as is necessary for the intended length of his yarn. He calls out, and another spinner immediately detaches the yarn from the hook of the whirl, gives it to another, who carries it aside to the reel; and this second spinner attaches his own hemp to the whirl-hook. In the mean time, the first spinner keeps fast hold of the end of his yarn; for the hemp, being dry, is very elastic, and if he were to let it go out of his hand, it would instantly untwist, and become little better than loose hemp. He waits, therefore, till he sees the reeler begin to turn the reel, and he goes slowly up the walk, keeping the yarn of an equal tightness all the way, till he arrives at the wheel, where he waits with his yarn in his hand till another spinner has finished his yarn. The first spinner takes it off the whirl-hook, joins it to his own, that it may follow it on the reel, and begins a new yarn.

Rope-yarns, for the greatest part of the large rigging, are from a quarter of an inch to somewhat more than a third of an inch in circumference, or of such a size that 160 fathoms weigh from $3\frac{1}{2}$ to 4 pounds when white. The different sizes of yarns are named from the number of them contained in a strand of a rope of three inches in circumference. Few are so coarse that 16 will make a strand of British cordage; 18 is not unfrequent for cable yarns, or yarns spun from harsh and coarse hemp; 25 is, we believe, the finest size which is worked up for the rigging of a ship. Much finer are indeed spun for sounding-lines, fishing-lines, and many other marine uses, and for the other demands of society. Ten good spinners will work up above 600 weight of hemp in a day; but this depends on the weather. In very dry weather the hemp is very elastic, and requires great attention to make smooth work. In the warmer climates the spinner is permitted to moisten the rag with which he grasps the yarn in his right hand for each yarn. No work can be done in an open spinning-walk in rainy weather, because the yarns would not take on the tar, if immediately tarred, and would rot if kept on the reel for a long time.

The second part of the process is the conversion of the yarns into what may with propriety be called a rope, cord, or line. That we may have a clear conception of the principle which regulates this part of the process, we shall begin with the simplest possible case, the union of two yarns into one line. This is not a very usual fabric for rigging, but we select it for its simplicity.

When hemp has been split into very fine fibres by the hatchel, it becomes exceedingly soft and pliant, and after it has lain for some time in the form of fine yarn, it may be unreeled and thrown loose, without losing much of its twist. Two such yarns may be put on the whirl of a spinning-wheel, and thrown, like flaxen yarn, so as to make sewing thread. It is in this way, indeed, that the sailmakers' sewing thread is manufactured; and when it has been kept on the reel, or on balls or bobbins, for some time, it retains its twist as well as its uses require. But this is by no means the case with yarns spun for great cordage. The hemp is so elastic, the number of fibres twisted together is so great, and the diameter of the yarn (which is a sort of lever on which the elasticity of the fibre exerts itself) is so considerable, that no keeping will make the fibres retain this constrained position. The end of a rope-yarn being thrown loose, it will immediately untwist, and this with considerable force and speed. It would, therefore, be a fruitless attempt to twist two such yarns together; yet the ingenuity of man has contrived to make use of this very tendency to untwist not only to counteract itself, but even to produce another and a permanent twist, which requires force to undo it, and which will recover itself when this force is removed. Every person must recollect, that when he had twisted a packthread very hard with his fingers between his two hands, if he slackens the thread by bringing his hands nearer together, the packthread will immediately curl up, running into loops or kinks, and will even twist itself into a neat and firm cord.

The component parts of a rope are called strands, and the operation of uniting them with a permanent twist is called laying or closing, the latter term being chiefly appropriated to cables and other very large cordage.

Lines and cordage less than 1½ inches circumference are laid at the spinning-wheel. The workman fastens the ends of each of two or three yarns to separate whirl-hooks. The remote ends are united in a knot. This is put on one of the hooks of a swivel called the loper, represented in fig. 213, and care is taken that the yarns are of equal length and twist. A piece of soft cord is put on the other hook of the loper; and, being put over a pulley several feet from the ground, a weight is hung on it, which stretches the yarn. When the workman sees that they are equally stretched, he orders the wheel to be turned in the same direction as when twining the yarns. This would twine them harder; but the swivel of the loper gives way to the strain, and the yarns immediately twist around each other, and form a line or cord. In doing this, the yarns lose their twist. This is restored by the wheel. But this simple operation would make a very bad line, which would be slack, and not hold its twist; for, by the turning of the loper, the strands twist immediately together, to a great distance from the loper. By this turning of the loper the yarns are untwisted. The wheel restores their twist only to that part of the yarns that remains separate from the others, but cannot do it in that part where they are already twined round each other, because their mutual pressure prevents the twist from advancing. It is, therefore, necessary to retard this tendency to twine, by keeping the yarns apart. This is done by a little tool called the top, represented in fig. 214.

It is a truncated cone, having three or more notches along its sides, and a handle called the staff. This is put between the strands, the small end next the loper, and it is pressed gently into the angle formed by the yarns which lie in the notches. The wheel being now turned, the yarns are more twisted, or hardened up, and their pressure on the top gives it a strong tendency to come out of the angle, and also to turn round. The workman does not allow this till he thinks the yarns sufficiently hardened. Then he yields to the pressure, and the top comes away from the swivel, which immediately turns round, and the line begins to lay. Gradually yielding to this pressure, the workman slowly comes up towards the wheel, and the laying goes on, till the top is at last close to the wheel, and the work is done. In the mean time, the yarns are shortened, both by the twining of each and the laying of the cord. The weight, therefore, gradually rises. The use of this weight is evidently to oblige the yarn to take a proper degree of twist, and not run into kinks.

A cord, or line, made in this way, has always some tendency to twist a little more. However little friction there may be in the loper, there is some, so that the turns which the cord has made in the laying, are not enough to balance completely the elasticity of the yarns; and the weight being appended, causes the strands to be more nearly in the direction of the axis, in the same manner as it would stretch and untwist a little any rope to which it is hung. On the whole, however, the twist of a laid line is permanent, and not like that upon thread doubled or thrown in a mill, which remains only in consequence of the great softness and flexibility of the yarn.

The process for laying or closing large cordage is considerably different from this. The strands of which the rope is composed consist of many yarns, and require a considerable degree of hardening. This cannot be done by a whirl driven by a wheel-band; it requires the power of a crank turned by the hand. The strands, when properly hardened, become very stiff, and when bent round the top, are not able to transmit force enough for laying the heavy and unpliant rope which forms beyond it. The elastic twist of the hardened strands must, therefore, be assisted by an external force. All this requires a different machinery and a different process.

At the upper end of the walk is fixed up the tackle-board, fig. 215. This consists of a strong oaken plank called a breast-board, having three or more holes in it, such as A, B, C, fitted with brass or iron plates. Into these are put iron cranks, called heavers, which have hooks or forelocks, and keys, on the ends of their spindles. They are placed at such a distance from each other, that the workmen do not interfere with each other while turning them round. This breast-board is fixed to the top of strong posts well secured by struts or braces facing the lower end of the walk. At the lower end is another breast-board fixed to the upright posts of a sledge, which may be loaded with stones or other weights. Similar cranks are placed in the holes of this breast-board. The whole goes by the name of the sledge; (see fig. 216). The top necessary for closing large cordage is too heavy to be held in the hand: it therefore has a long staff, which has a truck on the end. This rests on the ground; but even this is not enough in laying great cables. The top must be supported on a carriage, as shown in fig. 217, where it must lie very steady, and it needs attendance, because the master workman has sufficient employment in attending to the manner in which the strands close behind the top, and in helping them by various methods. The top is, therefore, fixed to the carriage by lashing its staff to the two upright posts. A piece of soft rope, or strap, is attached to the handle of the top by the middle, and its two ends are brought back and wrapped several times tight round the rope, in the direction of its twist, and bound down. This is shown at W, and it greatly assists the laying of the rope by its friction. This both keeps the top from flying too far from the point of union of the strands, and brings the strands more regularly into their places.

The first operation is warping the yarns. At each end of the walk are frames called warping frames, which carry a great number of reels or winches filled with rope-yarn. The foreman of the walk takes off a yarn end from each, till he has made up the number necessary for his rope or strand, and bringing the ends together, he passes the whole through an iron ring fixed to the top of a stake driven into the ground, and draws them through: then a knot is tied on the end of the hundle, and a workman pulls it through this ring till the intended length is drawn off the reels. The end is made fast at the bottom of the walk, or at the sledge, and the foreman comes back along the skain of yarns, to see that none are hanging slacker than the rest. He takes up in his hand such as are slack, and draws them tight, keeping them so till he reaches the upper end, where he cuts the yarns to a length, again adjusts their tightness, and joins them all together in a knot, to which he fixes the hook of a tackle, the other block of which is fixed to a firm post, called the warping-post. The skain is well stretched by this tackle, and then separated into its different strands. Each of these is knotted apart at both ends. The knots at their upper ends are made fast to the hooks of the cranks in the tackle-board; and those at the lower ends are fastened to the cranks in the sledge. The sledge itself is kept in its place by a tackle, by which the strands are again stretched in their places, and every thing adjusted, so that the sledge stands square on the walk, and then a proper weight is laid on it. The tackle is now cast off, and the cranks are turned at both ends, in the contrary direction to the twist of the yarns. (In some kinds of cordage the cranks are turned the same way with the spinning twist). By this the strands are twisted and hardened up; and as they contract by this operation, the sledge is dragged up the walk. When the foreman thinks the strands sufficiently hardened, which he estimates by the motion of the sledge, he orders the heavers at the cranks to stop. The middle strand at the sledge is taken off from the crank. This crank is taken out, and a stronger one put in its place at D, fig. 216. The other strands are taken off from their cranks, and are all joined on the hook which is now in the middle hole. The top is then placed between the strands, and being pressed home to the point of their union, the carriage is placed under it, and it is firmly fixed down. Some weight is taken off the sledge. The heavers now begin to turn at both ends. Those at the tackle-board continue to turn as they did before; but the heavers at the sledge turn in the opposite direction to their former motion, so that the cranks at both ends are now turning one way. By the motion of the sledge-crank the top is forced away from the knot, and the rope begins to close. The heaving at the upper end restores to the strand the twist which they are constantly losing by the laying of the rope. The workmen judge of this by making a chalk mark on intermediate points of the strands, where they lie on the stakes which are set up along the walk for their support. If the twist of the strands is diminished by the motion of closing, they will lengthen, and the chalk mark will move away from the tackle-board; but if the twist increases by turning the cranks at the tackle-board, the strands will shorten, and the mark will come nearer to it.

As the closing of the rope advances, the whole shortens, and the sledge is dragged up the walk. The top moves faster, and at last reaches the upper end of the walk, the rope being now laid. In the mean time, the sledge has moved several fathoms from the place where it was when the laying began.

These motions of the sledge and top must be exactly adjusted to each other. The rope must be of a certain length. Therefore the sledge must stop at a certain place. At that moment the rope should be laid; that is, the top should be at the tackle-board. In this consists the address of the foreman. He has his attention directed both ways. He looks at the strands, and when he sees any of them hanging slacker between the stakes than the others, he calls to the heavers at the tackle-board to heave more upon that strand. He finds it more difficult to regulate the motion of the top. It requires a considerable force to keep it in the angle of the strands, and it is always disposed to start forward. To prevent or check this, some straps of soft rope are brought round the staff of the top, and then wrapped several times round the rope behind the top, and kept firmly down by a lanyard or bandage, as is shown in the figure. This both holds back the top, and greatly assists the laying of the rope, causing the strands to fall into their places, and keep close to each other, which is sometimes very difficult, especially in ropes composed of more than three strands. It will greatly improve the laying the rope, if the top has a sharp, smooth, tapering pin of hard wood, pointed at the end, projecting so far from the middle of its smaller end, that it gets in between the strands which are closing. This supports them, and makes their closing more gradual and regular. The top, its notches, the pin, and the warp or strap, which is lapped round the rope, are all smeared with grease or soap to assist the closing. The foreman judges of the progress of closing chiefly by his acquaintance with the walk, knowing that when the sledge is abreast of a certain stake, the top should be abreast of a certain other stake. When he finds the top too far down the walk, he slackens the motion at the tackle-board, and makes the men turn briskly at the sledge. By this the top is forced up the walk, and the laying of the rope accelerates, while the sledge remains in the same place, because the strands are loosing their twist, and are lengthening, while the closed rope is shortening. When, on the other hand, he thinks the top too far advanced, and fears that it will be at the head of the walk before the sledge has got to its proper place, he makes the men heave briskly on the strands, and the heavers at the sledge-crank work softly. This quickens the motion of the sledge by shortening the strands; and by thus compensating what has been overdone, the sledge and top come to their places at once, and the work appears to answer the intention.

When the top approaches the tackle-board, the heaving at the sledge could not cause the strands immediately behind the top to close well, without having previously produced an extravagant degree of twist in the intermediate rope. The effort of the crank must therefore be assisted by men stationed along the rope, each furnished with a tool called a woolder. This is a stout oak stick, about three feet long, having a strap of soft rope-yarn or cordage fastened on its middle or end. The strap is wrapped round the laid rope, and the workman works with the stick as a lever, twisting the rope round in the direction of the crank's motion. The woolders should keep their eye on the men at the crank, and make their motion correspond with his. Thus they send forward the twist produced by the crank, without either increasing or diminishing it, in that part of the rope which lies between them and the sledge.

Such is the general and essential process of rope-making. The fibres of hemp are twisted into yarns, that they may make a line of any length, and stick among each other with a force equal to their own cohesion. The yarns are made into cords of permanent twist by laying them; and that we may have a rope of any degree of strength, many yarns are united in one strand, for the same reason that many fibres were united in one yarn; and in the course of this process it is in our power to give the rope a solidity and hardness which make it less penetrable by water, which would rot it in a short while. Some of these purposes are inconsistent with others; and the skill of a rope-maker lies in making the best compensation, so that the rope may on the whole be the best in point of strength, pliancy, and duration, that the quantity of hemp in it can produce.

The following rule for judging of the weight which a rope will bear is not far from the truth. It supposes them rather too strong; but it is so easily remembered that it may be of use.

Multiply the circumference in inches by itself, and take the fifth part of the product, it will express the tons which the rope will carry. Thus, if the rope has 6 inches circumference, 6 times 6 is 36, the fifth of which is $7\frac{1}{5}$ tons; apply this to the rope of $3,\frac{1}{5}$, on which sir Charles Knowles made his experiments $3\frac{1}{5} \times 3\frac{1}{5} = 10,25$, $\frac{1}{5}$ of which is 2,05 tons, or 4592 pounds. It broke with 4550.

This may suffice for an account of the mechanical part of the manufacture. But we have taken no notice of the operation of tarring; and our reason was, that the methods practised in different rope-works are so exceedingly different, that we could hardly enumerate them, or even give a general account of them. It is evidently proper to tar in the state of twine or yarn, this being the only way that the hemp could be uniformly penetrated. The yarn is made to wind off one reel, and having passed through a vessel containing hot tar, it is wound up on another reel; and the superfluous tar is taken off by passing through a hole surrounded with spongy oakum; or it is tarred in skains or hauls, which are drawn by a capstern through the tar-kettle, and through a hole formed of two plates of metal, held together by a lever loaded with a weight.

It is established beyond a doubt, that tarred cordage when new is weaker than white, and that the difference increases by keeping. The following experiments were made by Mr. Du Hamel at Rochefort on cordage of three inches (French) in circumference, made of the best Riga hemp.

	White.	Tarred.
	August 8, 1741.	
Broke with	4500 pounds.	3400 pounds.
	4900	3300
	4800	3250
	April 25, 1743.	
	4600	3500
	5000	3400
	5000	3400
	Sept, 3, 1746.	
	3800	3000
	4000	2700
	4200	2800

A parcel of white and tarred cordage was taken out of a quantity which had been made February 12, 1746. It was laid up in the magazines, and comparisons were made from time to time as follows:

	White bore.	Tarred bore.	Differ.
1746, April 14,	2645 lbs.	2312 lbs.	333
1747, May 18,	2762	2155	607
1747, Oct. 21,	2710	2050	660
1748, June 19,	2575	1752	823
1748, Oct. 2,	2425	1837	588
1749, Sept. 25,	2917	1865	1052

Mr. Du Hamel says, that it is decided by experience, 1. That white cordage in continual service is one-third more durable than tarred. 2. That it retains its force much longer while kept in store. 3. That it resists the ordinary injuries of the weather one-fourth longer.

We know this one remarkable fact: in 1758 the shrowds and stays of the Sheer hulk at Portsmouth dock-yard were over-hauled, and when the worming and service were taken off, they were found to be of white cordage. On examining the store-keeper's books, they were found to have been formerly the shrowds and rigging of the Royal William, of 110 guns, built in 1715, and rigged in 1716. She was thought top-heavy, and unfit for sea, and unrigged, and her stores laid up. Some few years afterwards, her shrowds and stays were fitted on the Sheer hulk, where they remained in constant and very hard service for about 30 years, while every tarred rope about her had been repeatedly renewed.

Why then do we tar cordage? It is chiefly serviceable for cables and ground tackle, which must be continually wetted, and even soaked. The result of careful observation is, 1. That white cordage, exposed to be alternately very wet and dry, is weaker than tarred cordage. 2. That cordage which is superficially tarred is constantly stronger than what is tarred throughout, and it resists better the alternatives of wet and dry. The shrowds of the Sheer hulk were well tarred and blacked, so that it was not known that they were of white cordage.

Attempts have been made to increase the strength of cordage by tanning. But although it remains a constant practice in the manufacture of nets, it does not appear that much addition, either of strength or durability, can be given to cordage by this means. The trial has been made with great care, and by persons fully able to conduct the process with propriety. But it is found that the yarns take so long time in drying, and are so much hurt by drying slowly, that the room required for a considerable rope-work would be immense; and the improvement of the cordage is but trifling, and even equivocal.

ROSA, the *rose*, a genus of the polygynia order, in the icosandria class of plants, and in the natural method ranking under the 35th order, senticosæ. There are five petals; the calyx is urceolated, quinquefid, carnous, and straitened at the neck. The seeds are numerous, hispid, and affixed to the inside of the calyx. The sorts of roses are very numerous; and the botanists find it very difficult to determine with accuracy which are species and which are varieties, as well as which are varieties of the respective species. On this account Linnæus, and some other eminent authors, are inclined to think that there is only one real species of rose, which is the rosa canina, or dog-rose of the hedges, &c. and that all the other sorts are accidental varieties of it. According, however, to the present arrangement, they stand divided into 40 supposed species, each comprehending varieties, which in some sorts are but few, in others numerous. The most remarkable species, and their varieties, according to the arrangement of modern botanists, are as follow:

1. The canina, canine rose, wild dog-rose of the hedges, or hep-tree. There are two varieties, red-flowered and white-flowered. They grow wild in hedges abundantly all over the kingdom; and are sometimes admitted into gardens; a few to increase the variety of the shrubbery collection.

2. The alba, or common white-rose. The varieties are; large double white rose; dwarf single white rose; maidens-blush white rose, being large, produced in clusters, and of a white and blueish-red colour.

3. The gallica, or Gallican rose, &c. This species is very extensive in supposed varieties, several of which have been formerly considered as distinct species, but are now ranged among the varieties of the Gallican rose, consisting of the following noted varieties.

Common red officinal rose. Rosa mundi (rose of the world) or striped red rose; York and Lancaster variegated rose; monthly rose, producing middle-sized, moderately-double, delicate flowers, of different colours in the varieties. The varieties are, common red-flowered monthly rose, blush-flowered, white-flowered, stripe-flowered: all of which blow both early and late, and often produce flowers several months in the year, as May, June, and July; and frequently again in August or September, and sometimes in fine mild seasons, continue till November or December. Hence the name monthly rose, double virgin rose.

4. The damascena, including the red damask rose, white damask rose, blueish Belgic rose, red Belgic rose. Velvet rose grows three or four feet high, armed with but few prickles; producing large velvet-red flowers, comprising semidouble and double varieties, all very beautiful roses. Marbled rose grows four or five feet high, having brownish branches, with but few prickles; and a large, double, finely-marbled, red flower.

5. The lutea, including the red and yellow Austrian rose, yellow Austrian rose, double yellow rose.

6. The centifolia, or hundred leaved red rose, &c. The varieties are; common Dutch hundred-leaved rose, bluish hundred-leaved rose.

7. The provincialis, or Provence rose. The varieties are; common red Provence rose, and pale Provence rose; both of which having larger and somewhat looser petals than the following sort. Cabbage Provence rose, having the petals closely folded over one another like cabbages; Dutch cabbage rose, very large, and cabbages tolerably; childing Provence rose; great royal rose, producing remarkably large, somewhat loose, but very elegant flowers. All these are large double red flowers, somewhat globular at first blowing, becoming gradually a little spreading at top, and are all very ornamental fragrant roses.

8. The muscosa, or moss Provence rose, supposed by some a variety of the common rose, having the calyx and upper part of the peduncle surrounded with a rough mossy-like substance, effecting a curious singularity.

9. The cinnamomea, or cinnamon rose. There are varieties with double-flowers.

10. The alpina, or Alpine inermous rose. This species, as being free from all kind of armature common to the other sorts of roses, is esteemed as a singularity; and from this property is often called the virgin rose.

11. The Carolina, or Carolina and Virginia rose, &c. grows six or eight feet high, or more. The varieties are; dwarf Pennsylvania rose, with single and double red flowers. American pale-red rose. This species and varieties grow naturally in different parts of North America; they effect a fine variety in our gardens, and are in estimation for their late-flowering property, as they often continue in blow from August until October; and the flowers are succeeded by numerous red berry-like heps in autumn, causing a variety all winter.

12. The villosa, or villose apple-bearing rose, grows six or eight feet high. This species merits admittance into every collection as a curiosity for the singularity of its fruit, both for variety and use; for having a thick pulp of an agreeable acid relish; this is often made into a tolerably good sweetmeat.

13. The pimpinellifolia, or burnet-leaved rose. There are varieties with red flowers, and with white flowers. They grow wild in England, &c. and are cultivated in shrubberies for variety.

14. The spinosissima, or most spinous, dwarf burnet-leaved rose, commonly called Scotch rose. The varieties are: common white-flowered, red-flowered, striped-flowered, marble-flowered. They grow naturally in England, Scotland, &c. The first variety rises near a yard high, the others, but one or two feet, all of which are single-flowered; but the flowers, being numerous all over the branches, make a pretty appearance in the collection.

15. The eglanteria, eglantine rose, or sweet-brier. The varieties are; common single-flowered, semi-double-flowered, double-flowered, blaish double-flowered, yellow flowered. This species grows naturally in some parts of England and Switzerland. It claims culture in every garden for the odoriferous property of its leaves; and should be planted in the borders, and other compartments contiguous to walks, or near the habitation, where the plants will impart their refreshing fragrance very profusely all around; and the young branches are excellent for improving the odour of nosegays and bowpots.

16. The moschata, or musk rose, supposed to be a variety only of the ever-green musk-rose; has all the branches terminated by large, umbellate clusters of pure white musk-scented flowers in August, &c.

17. The sempervirens, or evergreen musk-rose. The sempervirent property of this elegant species renders it a curiosity among the rose tribe; it also makes a fine appearance as a flowering shrub. There is one variety, the deciduous musk-rose above-mentioned. This species and variety flower in August, and is remarkable for producing them numerously in clusters, continuing in succession till October or November.

18. The semper flowers, or deep-red China rose, a most beautiful little plant, and well deserving the epithet of ever-blowing.

19. The chinensis, or pale China rose, which flowers almost the whole year.

These two last species were supposed to be so tender, as always to require the shelter of a green-house; but we can say from experience that they are nearly as hardy as any of our English roses.

The white and red roses are used in medicine. The former distilled with water yields a small portion of a butyraceous oil, whose flavour exactly resembles that of the roses themselves. This oil, and the distilled water, are very useful and agreeable cordials. These roses also, besides the cordial and aromatic virtues which reside in their volatile parts, have a mild purgative one, which remains entire in the decoction after distillation. The red rose, on the contrary, has an astringent and gratefully corroborating virtue.

ROSE. See Rosa.

ROSEMARY. See Rosmarinus.

ROSIDULA, a genus of the class and order pentandria monogynia. The calyx is five-leaved; corolla five-petalled; anthers scrotiform; capsule three-valved. There is one species, a suffructicose plant of the Cape.

ROSMARINUS, *rosemary*, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. The corolla is unequal, with its upper lip bipartite; the filaments are long, curved, and simple, each having a small dent. There are two species, the officinalis and chilensis. There are two varieties, of the first sort, one with white, striped leaves, called the silver rosemary, and the other with yellow, whence it is called the gold-striped rosemary. These plants grow naturally in the southern parts of France, Spain, and Italy; where, upon dry rocky soils near the sea, they thrive prodigiously, and perfume the air in such a manner as to be smelt at a great distance from the land. They are, however, hardly enough to bear the cold of our ordinary winters, provided they are planted upon a poor, dry, gravelly soil, on which they all endure the cold much better than in a richer ground, where, growing more vigorously in summer, they are more apt to be injured by frost in winter; nor will they have such a strong aromatic scent as those on a dry and barren soil. They are to be propagated either by slips or cuttings.

Rosemary has a fragrant smell, and a warm pungent bitterish taste, approaching to those of lavender: the leaves and tender tops are strongest; next to those, the cup of the flower; the flowers themselves are considerably the weakest, but most pleasant. Aqueous liquors extract a great share of the virtues of rosemary leaves by infusion, and elevate them in distillation: along with the water arises a considerable quantity of essential oil, of an agreeable strong penetrating smell. Pure spirit extracts in great perfection the whole aromatic flavour of the rosemary, and elevates very little of it in distillation. Hence the resinous mass left upon extracting the spirit, proves an elegant aromatic, very rich in the peculiar qualities of the plant. The flowers of rosemary give over great part of their flavour in distillation with pure spirit; by watery liquors, their fragrance is much injured; by beating, destroyed.

ROTALA, a genus of the monogynia order, in the triandria class of plants. The calyx is tridentate: there is no corolla; the capsule is trilocular and polyspermous. There is one species, an annual of the East Indies.

ROTANG. See CALAMUS.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immoveable line, which is called the axis of its rotation; and by such rotations it is, that solids are conceived to be generated.

The late ingenious M. de Moivre shews how solids, thus generated, may be measured or cubed. His method is this: for the fluxion of such solids, take the product of the fluxion of the absciss, multiplied by the circular base; and suppose the ratio of a square to the circle inscribed in it to be $\frac{n}{x}$: then the equation expressing the nature of any circle, whose diameter is d, is $yy = dx - xx$. Therefore $\frac{4dx\dot{x} - x^2\dot{x}}{n}$ is the fluxion of a portion of the sphere; and, consequently, the portion itself $4\frac{1}{2}d\dot{x}x - x\frac{1}{3}x^3$, and the circumscribed cylinder is $\frac{4dxx - x^3}{n}$; and therefore the portion of the sphere is to the portion of the circumscribed cylinder, as $\frac{1}{2}d - \frac{1}{3}x$ to $d - x$.

ROTHIA, a genus of the class and order syngenesia polygamia æqualis. The calyx is many-leaved in a single row; woolly recept. in the ray chaffy in the disk villose-seeds; in the ray bald in the disk pappose. There is one species.

ROTONDO, or ROTUNDO, in architecture, an appellation given to any building that is round both within and without, whether it is a church, a saloon, or the like.

ROTTBOELLIA, a genus of the digynia order, in the triandria class of plants. The rachis is jointed, roundish, and in many cases filiform: the calyx is ovate, lanceolated, flat, simple, or bipartite; the florets are alternate on the winding rachis. There are 17 species, grasses of Africa and the East Indies.

ROTTEN-STONE, a mineral found in Derbyshire, and used by mechanics for all sorts of finer grinding and polishing, and sometimes for cutting of stones. According to Ferber, it is a tripoli mixed with calcareous earth. See TRIPOLI.

ROUND, in a military sense, signifies a walk which some officer, attended with a party of soldiers, takes in a fortified place around the ramparts, in the night-time, in order to see that the centries are watchful, and every thing in good order.

The centries are to challenge the rounds at a distance, and rest their arms as they pass, to let none come near them; and when the round comes near the guard, the centry calls aloud, who comes there? and being answered, the rounds; he says, stand; and then calls the corporal of the guard, who draws his sword, and calls also, who comes there? and when he is answered, the rounds, he who has the word advances, and the corporal receives it with his sword pointed to the giver's breast. In strict garrison the rounds go every quarter of an hour.

ROUNDELAY, a kind of antient poem, thus termed, according to Menage, from its form, because it turns back again to the first verse, and thus goes round. This poem is little known among us, but is very common among the French, who call it rondeau. It consists commonly of thirteen verses, eight whereof are in one rhyme, and five in another. It is divided into couplets, at the end of the second and third of which the beginning of the roundelay is repeated, and that if possible in an equivocal or pausing sense.

ROUT, in law. See RIOT.

ROUSSEA, a genus of the tetrandria monogynia class and order. The calyx is four-leaved; corolla one-petalled, bell-shaped, four-cleft, inferior; berry quadrangular, many seeded. There is one species, a small shrub of St. Mauritius.

ROXBURGHIA, a genus of the octandria monogynia class and order. The calyx is four-leaved; corolla four-petalled; nectarines four, awl-shaped; anthers linear; capsule one-celled, two-valved; seeds many. There is one species, native of Coromandel.

ROYENIA, a genus of the digynia order, in the decandria class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is urceolated; the corolla monopetalous, with the limb revoluted; the capsule is unilocular and quadrivalved. There are seven species, herbs of the Cape.

RUBIA, *madder*, a genus of the monogynia order, in the tetrandia class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and campanulated; and there are two monospermous berries. There are seven species, of which the most remarkable is the tinctorum, or dyer's madder, so much used by the dyers and callico-printers. This hath a perennial root, and annual stalk: the root is composed of many long, thick, succulent fibres, almost as large as a man's little finger; these are joined at the top in a head like asparagus, and run very deep into the ground. From the upper part, or head of the root, come out many side-roots, which extend just under the surface of the ground to a great distance, by which it propagates very fast; for these send up a great number of shoots, which, if carefully taken off in the spring soon after they are above ground, become so many plants. These roots are of a reddish colour, somewhat transparent; and have a yellowish pith in the middle, which is tough, and of a bitterish taste. From this root arise many large four-cornered jointed stalks, which in good land will grow five or six feet long, and, if supported, sometimes seven or eight: they are armed with short herbaceous prickles; and at each joint are placed five or six spear-shaped leaves: their upper surfaces are smooth; the branches are terminated by loose branching spikes of yellow flowers, which are cut into four parts resembling stars. These appear in June, and are sometimes succeeded by seeds, which seldom ripen in England. For its principal uses, see DYEING, and CALICO PRINTING.

Madder-root is used in medicine. The virtues attributed to it are those of a detergent and aperient; whence it has been usually ranked among the opening roots, and recommended in obstructions of the viscera, particularly of the kidneys, in coagulations of the blood from falls or bruises, in the jaundice, and beginning dropsies. It is an ingredient in the icteric decoction of the Edinburgh pharmacopœia.

It is observable, that this root, taken internally, tinges the urine of a deep red colour; and in the Philosophical Transactions we have an account of its producing a like effect upon the bones of animals who had it mixed with their food: all the bones, particularly the more solid ones, were said to be changed, both externally and internally, to a deep red; but neither the fleshy nor cartilaginous parts suffered any alterations: some of these bones macerated in water for many weeks together, and afterwards steeped and boiled in spirit of wine, lost none of their colour, nor communicated any tinge to the liquors. This root, therefore, was concluded to be possessed of great subtilty of parts, and its medical virtues hence to deserve inquiry. The same trials, however, made by others, have not been found to produce the same effects as those above mentioned. Of late the root has come into great reputation as an emmenagogue.

RUBRIC, in the canon law, signifies a title or article in certain antient law-books; thus called because written, as the titles of the chapters in our antient bibles are, in red letters. Rubrics also denote the rules and directions given at the beginning, and in the course of, the liturgy, for the order and manner in which the several parts of the office are to be performed. There are general rubrics and special rubrics, a rubric for the communion, &c. In the Romish Missal and Breviary are rubrics for matins, for lauds, for translations, beatifications, commemorations, &c.

RUBUS, the *bramble*, a genus of the polygamia order, in the icosandria class of plants; and in the natural order ranking under the 35th order, senticosæ. The calyx is quinquefid, the petals five; the berry consisting of monospermous acini or pulpy grains. The principal species is the idæus, or common raspberry, which, with its varieties, demands culture in every garden for their fruit; particularly the common red kind, white sort, and twice-bearing raspberry; all of which are great bearers: but, for the general plantations, we choose principally the common red and the white kind, as being generally the greatest bearers of all; planting also a share of the twice-bearing sort, both as a curiosity, and for the sake of its autumnal crops of fruit, which in favourable seasons ripen in tolerable perfection; observing to allow all the sorts some open exposure in the kitchen garden, though they will prosper in almost any situation.

Some other species are considered as plants of variety, for hardy plantations in the shrubbery. Some of them are also very ornamental flowering plants; particularly the Virginian flowering raspberry, and the double-blossomed bramble, which have great merit as furniture for ornamental compartments; and the white-berried bramble, which is a great curiosity.

RUBY, a genus of precious stones of various colours; as, 1. Of a deep red colour, inclining a little to purple: the carbuncle of Pliny. 2. The spinell, of the colour of a bright corn poppy flower. 3. The balass, or pale red, inclining to violet. 4. The rubicell, of a reddish yellow. According to Cronstedt, the ruby crystallises into an octoedral form, as well as the diamond, from which it differs very little in hardness and weight. Tavernier and Dutens inform us, that in the East Indies all coloured gems are named rubies, without regard to what their colours may be; and that the particular colour is added to the name of each, in order to distinguish them from one another. There are, however, some soft stones of this kind, which they call bacan: and it is certain, that the hard and brilliant rubies, named oriental, as well as the sapphires and topazes, are all the same, excepting only the circumstance of colour. Some are partly red, and partly blue, yellow, and some quite colourless. The spinell rubies are about half the value of diamonds of the same weight; the balass is valued at 30 shillings per carat. Tavernier mentions 108 rubies in the throne of the great Mogul, from 100 to 200 carats, and of a round one almost $2\frac{1}{4}$ ounces: there is also mention made by other travellers, of rubies exceeding 200 carats in weight. According to Dutens, a perfect ruby, if it weighs more than $3\frac{1}{2}$ carats, is of greater value than a diamond of the same weight. If it weighs one carat, it is worth 10 guineas; if two carats, 40 guineas; three carats, 150 guineas; if six carats, upwards of 1000 guineas.

According to the experiments of Bergman and Achard, the texture of the ruby is foliated like that of diamonds: it is fusible with borax in a strong and long-continued heat, running into a transparent glass of a pale green colour. From the experiments of M. d'Arcet, it appears that the ruby does not lose its colour in the greatest fire; but Henckel says, that, by means of a burning glass, he softened it in such a manner as to receive the impression of a seal of jasper. It becomes electric by being rubbed. Its specific gravity, according to Bergman, is from 3,180 to 4,240: but Brisson tells us that it is 4,283. The specific gravity of the spinell is 3,760, of the Brasilian ruby 3,531.

Rubies are met with in the Capelan mountains of Pegu, in the East Indies; and at Caos, Ava, Bisnagar, Calicut, Cananor, Ceylon, and Brasil. They are found in sands of rivers of a red colour, in an argillaceous earth of a hard texture and greenish colour; sometimes they adhere to red rocks. The spinell rubies are met with in Hungary, Silesia, Bohemia, and Brasil. The balass comes principally from Brasil, though some are also brought from the East Indies. The rubicell comes also from Brasil, but they are said to lose their colour in the fire. See Corandum, Topaz, &c.

RUDBECKIA, *dwarf sun-flower*, in botany, a genus of the syngenesia-polygamia frustranea class of plants, the compound flower of which is radiated; but the hermaphrodite corollulæ of the disc are tubulose and very numerous: the stamina are five very short capillary filaments; and there is a small orbiculated seed after each of the hermaphrodite corollulæ, and are all contained in the cup, affixed to a paleaceous receptacle. There are seven species.

RUDDER, in navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side to the water, and sometimes another, turns or directs the vessel this way or that. See Ship-Building.

The rudder of a ship is a piece of timber hung on the stern-posts by four or five iron hooks, called pintles, serving for the bridle of a ship to turn her about at the pleasure of the steersman. The rudder being perpendicular, and withoutside the ship, another piece of timber is fitted to it at right angles, which comes into the ship, by which the rudder is managed and directed. This latter properly is called the helm or tiller; and sometimes, though improperly, the rudder itself. The power of the rudder is reducible to that of the lever. As to the angle the rudder should make with the keel, it is shewn, that in the working of ships, in order to stay or bear up the soonest possible, the tiller of the ruder ought to make an angle of 55° with the keel. A narrow rudder is best for a ship's sailing, provided she can feel it; that is, be guided and turned by it: for a broad rudder will hold much water when the helm is put over to any side; but if a ship has a fat quarter, so that the water cannot come quick and strong to her rudder, she will require a broad rudder. The aft-most part of the rudder is called the rake of the rudder.

RUELLIA, in botany, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is quinquepartite; the corolla sub-campanulated; the stamina approaching together in pairs; the capsule springing asunder by means of its elastic segments. There are 43 species, shrubs of the East and West Indies.

RUFF. See Perca.

Ruff. See Tringa.

RUIZIA, a genus of the polyandria order, in the monadelphia class of plants; and in the natural method ranking under the 37th order, columniferæ. The calyx is double; the external are triphyllous. The corolla consists of five petals, inclining to the right hand side, and adhering to the stamina, which are from 30 to 40. It has ten styli, and as many capsulæ. These are compressed and membranous. In each capsule are two seeds. There are three species, viz. 1. Cordata; 2. Lobata; 3. Vanibilis; all natives of Asia and the Cape of Good Hope.

RULES *of court*, in law, are certain orders made, from time to time, in the courts of law, which attornies are bound to observe, in order to avoid confusion; and both the plaintiff and defendant are at their peril also bound to pay obedience to rules made in court relating to the cause depending between them.

It is to be observed, that no court will make a rule for any thing that may be done in the ordinary course; and that if a rule is made, grounded upon an affidavit, the other side may move the court against it, in order to vacate the same, and thereupon shall bring into court a copy of the affidavit and rule. On the breach and contempt of a rule of court, an attachment lies; but it is not granted for disobedience to a rule when the party has not been personally served; nor for disobeying a rule made by a judge in his chamber, which is not of force to ground a motion upon, unless the same is entered.

Rule, or *Ruler*, an instrument of wood or metal, with several lines delineated on it, of great use in practical mensuration.

When a ruler has the lines of chords, tangents, sines, &c. it is called a plane scale.

The carpenter's joint-rule is an instrument usually of box, &c. twenty-four inches long, and one and a half broad; each inch being subdivided into eight parts. On the same side with these divisions, is usually added Gunter's line of numbers. On the other side, are the lines of timber and board-measure; the first beginning at 82, and continued to 36, near the other end; the latter is numbered from 7 to 36, four inches from the other end.

Use of the carpenter's joint-rule. The application of the inches, in measuring lengths, breadths, &c. is obvious.

The use of the other side is all we need here to notice. 1. The breadth of any surface, as board, glass, &c. being given, to find how much in length makes a square foot. Find the number of inches the surface is broad, in the line of broad-measure, and right against it is the number of inches required. Thus, if the surface was eight inches broad, eighteen inches will be found to make a superficial foot. Or more readily thus: Apply the rule to the breadth of the board, or glass, that end, marked 36, being equal with the edge, the other edge of the surface will shew the inches, and quarters of inches, which go to a square foot. 2. Use of the table at the end of the board-measure. If a surface is one inch broad, how many inches long will make a superficial foot? look in the upper row of figures for one inch, and under it in the second row is twelve inches, the answer to the question. 3. Use of the line of timber-measure. This resembles the former; for having learned how much the piece is square, look for that number on the line of the timber-measure; the space thence to the end of the rule is the length which, at that breadth, makes a foot of timber. Thus, if the piece is nine inches square, the length necessary to make a solid foot of timber, is 21 $\frac{1}{3}$ inches. If the timber is small, and under nine inches square, seek the square in the upper rank of the table, and immediately under it are the feet and inches that make a solid foot. If the piece is not exactly square, but broader at one end than the other, the method is to add the two together, and take half the sum for the side of the square. For round timber the method is to girt it round with a string, and to allow the fourth part for the side of the square; but this method is erroneous, for hereby you lose nearly one-fifth of the true solidity; though this is the method at present practised in buying and selling timber.

The mason's rule is twelve or fifteen feet long, in order to be applied under the level to regulate the courses, and make the piedroits equal, &c.

Everard's sliding Rule. See GAUGING.

RUM, a species of brandy, or vinous spirit, distilled from sugar-canes. See DISTILLATION, and SPIRIT.

RUMEN, in comparative anatomy, the paunch, or first stomach of such animals as chew the cud, thence called ruminant animals. See COMPARATIVE ANATOMY.

RUMEX, *dock*, a genus of the trigynia order, in the hexandria class of plants; and in the natural method ranking under the 12th order, holoraceæ. The calyx is triphyllous; there are three connivent petals, and one triquetrous seed. There are 36 species; of which the most remarkable are: 1. The patientia, commonly called patience rhubarb. This was formerly much more cultivated in the British gardens than at present: the roots of this have been generally used for the monk's rhubarb, and it has even been thought to be the true kind; but others suppose the second sort should be used as such. 2. The alpinus, or monk's rhubarb, grows naturally on the Alps, but has long been cultivated in the gardens of this country. This has large roots, which spread and multiply by their offsets: they are shorter and thicker than the former, are of a very dark brown on the outside, and yellow within. 3. The aquaticus, or water-dock, grows naturally in ponds, ditches, and standing waters, in many parts of Britain. It is supposed to be the herba Britannica of the antients. 4. The acutus, or sharp-pointed dock (the oxylapathum of the shops); but the markets are supplied with roots of the common docks, which are indifferently gathered by those who collect them in the fields, where the kind commonly called butter dock (from its leaves being used to wrap up butter) is much more common than this. These plants are but seldom cultivated, and so easily multiply by their numerous seeds, that they soon become troublesome weeds where they once get an entrance.

RUMINANT, in natural history, is applied to an animal which chews over again what it has eaten before; which is popularly called chewing the cud. Payer, in a treatise De Ruminantibus et Ruminatione, shews that there are some animals which really ruminate; as oxen, sheep, deer, goats, camels, hares, and squirrels; and that there are others which only appear to do so, as moles, crickets, bees, beetles, crabs, mullets, &c. The latter class, he observes, have their stomachs composed of muscular fibres, by which the food is ground up and down as in those which really ruminate. Mr. Ray observes, that ruminants are all four-footed, hairy, and viviparous; some with hollow and perpetual horns, others with deciduous ones.

RUMPHIA, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is trifid; the petals three; the fruit a trilocular plum. There is one species, a tree of the East Indies.

RUNDLE, or ROUNDLLE. See HERALDRY.

RUNDLET, or RUNLET, a small vessel, containing an uncertain quantity of any liquor, from three to twenty gallons.

RUNNER, in the sea language, a rope belonging to the garnet, and to the two bolt-tackles. It is reeved in a single block, joined to the end of a pennant, and has at one end a hook to hitch into any thing, and at the other end a double block, into which is reeved the fall of the tackle, or the garnet, by which means it purchases more than the tackle would without it.

RUNNET, or RENNET, is the juice or gastric fluid found in the stomachs of sucking quadrupeds, which as yet have received no other nourishment than their mother's milk. In ruminating animals, which have several stomachs, it is generally found in the last, though sometimes in the next to it. If the runnet is dried in the sun, and then kept close, it may be preserved in perfection for years. Not only the runnet itself, but also the stomach in which it is found, curdles milk without any previous preparation. But the common method is, to take the inner membrane of a calf's stomach, to clean it well, to salt and hang it up in brown paper: when this is used, the salt is washed off, then it is macerated in a little water during the night, and in the morning the infusion is poured into the milk to curdle it. See DIGESTION, Vol. I. p. 521, col. 3.

RUPALA, a genus of the tetrandria monogynia class and order. There is no calyx; the petals are four; stamina inserted in the middle of the petals; pericarpium one-celled, two-seeded.

RUPERT'S DROPS, a sort of glass-drops with long and slender tails, which burst to pieces on the breaking off those tails in any part; said to have been invented by prince Rupert, and therefore called by his name. Concerning the cause of this surprising phænomenon scarcely any thing that bears the least appearance of probability has been offered. Their explosion is attended in the dark with a flash of light; and, by being boiled in oil, the drops are deprived of their explosive quality.

RUPPIA, a genus of the tetragynia order, in the tetrandria class of plants; and in the natural method ranking under the 15th order, inundatæ. There is neither calyx nor corolla; but four pedicellated seeds. There is one species.

RUPTURE, in surgery, the same with hernia. See SURGERY.

RUSCUS, *knee-holly*, or *butcher's broom*, a genus of the syngenesia order, in the diœcia class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. The male calyx is hexaphyllous; there is no corolla; the nectarium is central, ovate, and perforated at the top. The female calyx, corolla, and nectarium, are the same as in the male; there is one style, with a trilocular two-seeded berry. There are five species. The most remarkable is the aculeatus, or common butcher's broom, common in the woods in many parts of England. As this plant grows wild in most parts of England, it is rarely admitted into gardens; but if some of the roots are planted under tall trees in large plantations, they will spread into large clumps; and as they retain their leaves in winter, at that season they will have a good effect. The seeds of this plant generally lie a year in the ground before they vegetate; and the plants so raised are long before they arrive at a size large enough to make any figure, and therefore it is much better to transplant the roots. The root of this plant is accounted aperient, and in this intention is sometimes made an ingredient in apozems and diet-drinks, for opening slight obstructions of the viscera, and promoting the fluid secretions. This plant is used by the butchers for besoms to sweep their blocks. Hucksters place the boughs round their bacon and cheese, to defend them from the mice; for they cannot make their way through the prickly leaves.

RUSH, in botany. See JUNCUS.

RUSSELIA, a genus of the didynamia angiospermia class and order. The calyx is five-leaved; corolla tube, very long; capsule acuminate. There is one species, a shrubby plant of the Havannah.

RUSSIA COMPANY, in commerce. See COMPANY.

RUST, the oxide of a metal. Iron, for instance, when exposed to the air, soon becomes tarnished, and gradually changed into a brown or yellow powder, well known by the name of rust. This change is occasioned by the gradual combination of the iron with the oxygen of the atmosphere, and, according to the new chemistry, it is now denominated the oxide of iron.

RUSTIC, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art.

RUTA, *rue*, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 26th order, multisiliquæ. The calyx is quinquepartite; the petals concave; the receptacle surrounded with 10 melliferous pores; the capsule is lobed. In some flowers, a fifth part of the number is excluded. There are seven species, of which the most remarkable is the hortensis, or common broad-leaved garden rue, which has been long cultivated for medicinal use.

Rue has a strong ungrateful smell, and a bitterish penetrating taste: the leaves, when full of vigour, are extremely acrid, insomuch as to inflame and blister the skin, if much handled.

RUTHILE, an ore found in Hungary, Italy, and France. It is generally crystallized. The primitive form of the crystals is a rectangular prism, whose base is a square, and the form of its molecules is a triangular prism, whose base is a right-angled isosceles triangle; and the height is to any of the sides of the base about the right angle, nearly as three to five. Specific gravity from 4.18 to 4.24. It is not affected by the mineral acids.

RUYSCHIA, in botany, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is pentaphyllous; the corolla is pentapetalous; and the berry many-seeded. There are two species, parasitical shrubs of Guiana.

RYANIA, a genus of the polyandria monogynia class and order. The calyx is five-leaved; corolla none; stigmas four; berry suberous, one-celled, many-seeded. There is one species, a tree of Trinidad.

RYE. See Secale.

RYNCHOPS, *skimmer*, in ornithology, a genus belonging to the order of anseres. The bill is straight: and the superior mandible much shorter than the inferior, which is truncated at the point. The species are two, viz. the nigra and fulva, both natives of America. The fulva is perpetually flying about and skimming over water, out of which it scoops small fish with its lower mandible: in stormy seasons it frequents the shores in search of shell-fish. See Plate Nat. Hist. fig. 348.

S

S, the eighteenth letter of our alphabet, in abbreviations stands for societas, or socius; as R. S. S. for regiæ societatis socius, *i. e.* fellow of the royal society. In medicinal prescriptions, S. A. signifies secundum artem, *i. e.* according to the rules of art; and in the notes of the antients, S. stands for Sextus; SP. for spurius; S. C. for senatus consultum; S. P. Q. R. for senatus populusque Romanus; S. S. S. for stratum super stratum, *i. e.* one layer above another alternately; S. V. B. E. E. Q. V. for si vales bene est, ego quoque valeo, a form used in Cicero's time, in the beginning of letters. Used as a numeral, S. antiently denoted seven; in the Italian music, S. signifies solo; and in books of navigation, S. stands for south; S. E. for south-east; S. W. for south-west; S. S. E. for south-south-east; S. S. W. for south-south-west. See Compass.

SABELLA, a genus of vermes testacea: animal a nereis, with a ringent mouth, and two thicker tentacula behind the head: shell tubular, composed of particles of sand, broken shells, and vegetable substances united to a membrane by a glutinous cement. There are 24 species.

SABELLIANS, a sect of Christians of the third century, who embraced the opinions of Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the Godhead.

SABLE. See Mustela.

Sable. See Heraldry.

SABURRÆ. See Gritt.

SACBUT, a bass wind-instrument, resembling the trumpet, so contrived as to be capable of being drawn out to different lengths, according to the acuteness and gravity of the scale required.

The sacbut is usually about eight feet long, and when extended to its full length, about fifteen. There are, however, sacbuts of different sizes to execute different parts; particularly a small one called by the Italians trombone picciolo, and the Germans cleine alt possaune, proper for the counter-tenor.

SACCHARINE ACID. See Oxalic Acid.

SACCHARUM, *sugar*, or the *sugar-cane*, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is two-valved; the corolla is also bivalved. There are eleven species of this genus. The most remarkable is the officinarum. It is a native of Africa, the East Indies, and of Brazil, whence it was introduced into our West India islands soon after they were settled. In the manner of their growth, form of their leaves, and make of their panicle, the sugar-canes resemble the reeds which grow in wet marshy grounds in England, or elsewhere; except that the canes are far larger, and, instead of being hollow as the reeds, are filled with a white pith, containing the sweet juice or liquid, which stamps such value upon these plants. The intermediate distance between each joint of a cane is of different lengths, according to the nature of the soil, richness of the manure, and different temperature of the weather during its growth; it seldom exceeds, however, four inches in length, and an inch in diameter. The length of the whole cane likewise depends upon the above circumstances. It generally grows to perfection in about fourteen months, when its height, at a medium, is about six feet, sometimes more, sometimes less. The body of the cane is strong, but brittle; of a fine straw-colour, inclining to a yellow. The extremity of each is covered, for a considerable length, with many long grassy leaves or blades, sharply and finely sawed on their edges; the middle longitudinal rib being high and prominent. The sugar-cane is propagated by planting cuttings of it in the ground in furrows, dug parallel for that purpose; the cuttings are laid level and even, and are covered up with earth; they soon shoot out new plants from their knots or joints; the ground is to be kept clear, at times, from weeds; and the canes grow so quick, that in eight, ten, or twelve months, they are fit to cut for making of sugar from them. When ripe, they cut off the reeds at one of the joints near the roots; they are then cleared of the leaves, and tied up in bandles, and sent to the mills, which are worked either by water or horses.

The bottom part of the sugar-cane top is about the thickness of one's finger; and as it contains a good deal of the natural sweetness of the plant, it is usually cut into pieces of an inch and a half long, and given to the saddle-horses in the West Indies. It is very nourishing food, and fattens them apace. The mill-horses, mules, and asses, are likewise fed, during crop time, on sugar-cane tops and the skimming of the sugar-coppers; which last must be administered sparingly at first, for fear of griping, and perhaps killing them. For the manufacture, &c. of sugar, see Sugar.

SACCOLATS, salts formed from the saclactic acid, and but little known. 1. Saccolat of potass, small crystals soluble in eight times their weight of water. 2. Saccolat of soda, the same, soluble in five times their weight of water. 3. Saccolat of ammonia, has a sourish taste: heat separates the ammonia. Saccolat of lime, of barytes, of magnesia, and of alumina, are all insoluble in water.

SACK *of wool*, a quantity of wool containing just twenty-two stone, and every stone fourteen pounds. In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

Sack *of cotton-wool*, a quantity from one hundred and a half to four hundredweight.

Sacks *of earth*, in fortification, are canvas bags filled with earth. They are used in making intrenchments in haste, to place on parapets, or the head of the breaches, &c. or to repair them, when beaten down.

SACLACTIC ACID. This acid was discovered by Scheele in 1780. After having obtained oxalic acid from sugar, he wished to examine whether the sugar of milk would furnish the same product. Upon four ounces of pure sugar of milk, finely powdered, he poured twelve ounces of diluted nitric acid, and put the mixture into a large glass retort, which he placed in a sand-bath. A violent effervescence ensuing, he was obliged to remove the retort from the sand-bath till the commotion ceased. He then continued the distillation till the mixture became yellow. As no crystals appeared in the liquor remaining in the retort after standing two days, he repeated the distillation as before, with the addition of eight ounces of nitric acid, and continued the operation till the yellow colour, which had disappeared on the addition of the nitric acid, returned. The liquor in the retort contained a white powder, and when cold, was observed to be thick. Eight ounces of water were added to dilute this liquor, which was then filtrated, by which the white powder was separated; which being edulcorated and dried, weighed 7½ drachms. The filtrated solution was evaporated to the consistence of a syrup, and again subjected to distillation, with four ounces of nitric acid as before; after which, the liquor, when cold, was observed to contain many small, oblong, sour crystals, together with some white powder. This powder being separated, the liquor was again distilled with more nitric acid, as before; by which means the liquor was rendered capable of yielding crystals again; and by one distillation more, with more nitrous acid, the whole of the liquor was converted into crystals. These crystals, added together, weighed five drachms; and were found, upon trial, to have the properties of the oxalic acid.

Mr. Scheele next examined the properties of the white powder, and found it to be an acid of a peculiar nature; he therefore called it the acid of sugar of milk. It was afterwards called saclactic acid by the French chemists. Fourcroy has lately given it the name of mucous acid, because it is obtained by treating gum arabic, and other mucilaginous substances, with nitric acid.

Mr. Hermstadt, of Berlin, had made similar experiments on sugar of milk at the same time with Scheele, and with similar results; but he concluded that the white powder which he obtained was nothing else than oxalat of lime with excess of acid, as indeed Scheele himself did at first. After he became acquainted with Scheele's conclusions, he published a paper in defence of his own opinions; but his proofs are very far from establishing it, or even rendering its truth probable. He acknowledges himself, that he has not been able to decompose this supposed salt: he allows that it possesses properties distinct from the oxalic acid; but he ascribes this difference to the lime which it contains; yet all the lime which he could discover in 240 grains of this salt was only 20 grains; and if the alkali which he employed was a carbonat (as it probably was), these 20 must be reduced to 11. Now Morveau has shewn, that oxalic acid, containing the same quantity of lime, exhibits very different properties. Besides, this acid, whatever it is, when united with lime, is separated by the oxalic, and must therefore be different from it: as it would be absurd to suppose that an acid could displace itself. The saclactic acid must therefore be considered as a distinct acid, since it possesses peculiar properties.

1. Saclactic acid may be obtained by the following process: Upon one part of gum arabic, or other similar gum, previously put into a retort, pour two parts of nitric acid. Apply a slight heat for a short time, till a little nitrous gas and carbonic acid gas comes over; then allow the mixture to cool. A white powder gradually precipitates, which may easily be separated by filtration. This powder is saclactric acid.

2. Saclactric acid, thus obtained, is under the form of a white gritty powder, with a slightly acid taste.

Heat decomposes it. When distilled, there comes over an acid liquor which crystallizes in needles on cooling, a red-coloured acrid oil, carbonic acid gas, and carbureted hydrogen gas. There remains in the retort a large proportion of charcoal.

Saclactic acid, according to Scheele, is soluble in 60 parts of its weight of boiling water; but Messrs. Hermstadt and Morveau found, that boiling water only dissolved $\frac{1}{80}$th part: it deposited about $\frac{1}{4}$th part on cooling in the form of crystals.

The solution has an acid taste, and reddens the infusion of turnsole. Its specific gravity, at the temperature of 53.7°, is 1.0015. The compounds which it forms with earths, alkalies and metallic oxides are denominated saccolats.

SAFFRON. See CROCUS.

SAGAPENUM, *gum resins*. See PHARMACY.

SAGATHEE, in commerce, a slight kind of woollen stuff, serge, or ratteen, sometimes mixed with a little silk.

SAGE. See SALVIA.

SAGENE, a Russian long measure, five hundred of which make a werst. The sagene is equal to seven English feet.

SAGENITE. See RUTHILE.

SAGINA, *pearlmist*, a genus of the tetragynia order, in the tetrandia class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is tetraphyllous; the petals four; the capsule is unilocular, quadrivalved and polyspermous. There are 5 species.

SAGITTA, in astronomy, the arrow or dart, a constellation of the northern hemisphere, near the eagle. See ASTRONOMY.

SAGITTA, in trigonometry, the same with the versed sine of an arch.

SAGITTARIA, *arrow-head*, a genus of the polyandria order, in the monœcia class of plants, and in the natural method ranking under the fifth order, tripetaloideæ. The male calyx is triphyllous; the corolla tripetalous; the filaments generally about 14: the female calyx is triphyllous; the corolla tripetalous; many pistils; and many naked seeds. There are five species, of which the most remarkable is the sagittifolia, growing naturally in many parts of England. The root is composed of many strong fibres, which strike into the mud; the footstalks of the leaves are in length proportionable to the depth of the water in which they grow; so they are sometimes almost a yard long: they are thick and fungous: the leaves, which float upon the water, are shaped like the point of an arrow, the two ears at their base spreading wide asunder, and are very sharp-pointed. There is always a bulb at the lower part of the root, growing in the solid earth beneath the mud. This bulb constitutes a considerable part of the food of the Chinese; and upon that account they cultivate it. Horses, goats, and swine, eat it; cows are not fond of it.

SAGITTARIUS, the *archer*, in astronomy, the ninth sign of the zodiac. See ASTRONOMY.

SAGO, a simple brought from the East Indies, of considerable use in diet as a restorative. It is produced from the ~~pith of~~ a kind of palm which grows in the East Indies, called the cycas circinalis. See CYCAS, STARCH, &c.

SAHLITE, another name for malacolite, which see.

SAIL, in navigation. See SHIP-BUILDING.

SALE. If a man agrees for the purchase of goods, he shall pay for them before he carries them away, unless some term of a credit is expressly agreed upon.

If one man says the price of an article is 100*l*. and the other says I will give you 100*l*. but does not pay immediately, it is at the option of the seller whether he shall have it or no, except a day was given for the payment.

If a man upon the sale of goods, warrants them to be good, the law annexes to this contract a tacit warranty, that if they are not so, he shall make compensation to the purchaser; such warranty, however, must be on the sale. But if the vendor knew the goods to be unsound, and has used any art to disguise them, or if in any respect they differ from what he represents them to be to the purchaser, he will be answerable for their goodness, though no general warranty will extend to those defects that are obvious to the senses.

If two persons come to a warehouse, and one buys, and the other to procure him credit, promises the seller, if he does not pay you, I will; this is a collateral undertaking, and void without writing, by the statutes of frauds; but if he says, let him have the goods, I will be your pay-master, this is an absolute undertaking as for himself, and he shall be intended to be the real buyer, and the other to act only as his servant. 2 T. R. 73.

After earnest is given, the vendor cannot sell the goods to another without a default in the vendee; and therefore if the vendee does not come and pay, and take the goods, the vendor ought to give him notice for that purpose; and then if he does not come and pay, and take away the goods in convenient time, the agreement is dissolved, and he is at liberty to sell them to any other person. 1 Salk. 113.

An earnest only binds the bargain, and gives the party a right to demand; but demand without payment of money is void. See also AUCTION, CONTRACT, &c.

SALEP. See STARCH.

SALIANT, in fortification, denotes projecting. There are two kinds of angles: the one saliant, which are those that present their point outwards; the other re-entering, which have their points inwards. Instances of both kinds we have in tenailles and star-works.

SALIENT. See HERALDRY.

SALIC, or SALIQUE LAW, *lex salica*, an antient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue of which males are only to inherit. Du Haillan, after a critical examination, declares it to have been an expedient of Philip the Long, in 1316, for the exclusion of the daughter of Lewis Hutin from inheriting the crown. Father Daniel, on the other hand, maintains that it is quoted by authors more antient than Philip the Long, and that Clovis is the real author of it. This law has not any particular regard to the crown of France; it only imports, in general, that in salic land no part of the inheritance shall fall to any female, but the whole to the male sex. By salic lands, or inheritances, were antiently denoted, among us, all lands, by whatever tenure held, whether noble or base, from the succession to which women were excluded by the salic law; for they were by it admitted to inherit nothing but moveables and purchases wherever there were any males.

SALISBURIA, a genus of the class and order monœcia polyandria. The male is an ament; antheræ incumbent; female solitary; calyx four-cleft, drupe. There is one species, a tree of Japan.

SALICORNIA, *jointed glass-wort*, or *salt-wort*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is ventricose, or a little swelling out and entire; there are no petals, and but one seed. There are nine species, of which the most remarkable are: 1. The fruticosa, with obtuse points, grows plentifully in most of the salt marshes which are overflowed by the tides in many parts of England. It is an annual plant, with thick, succulent, jointed stalks, which trail upon the ground. 2. The perennis, with a shrubby branching stalk, grows naturally in Sheppey island. They are perennial, and produce their flowers in the same manner as the former. The inhabitants near the sea-coasts where these plants grow, cut them up toward the latter end of summer, when they are fully grown; and after having dried them in the sun, they burn them for their ashes, which are used in making of glass and soap. These herbs are by the country people called kelp, and promiscuously gathered for use.

SALIVA. The fluid secreted in the mouth, which flows in considerable quantity during a repast, is known by the name of saliva. All the properties of this liquor which had been observed by philosophers before the middle of the 18th century have been collected by Haller; but since that time several additional facts have been related by Fourcroy, Du Tennetar, and Brugnatelli, and a very numerous set of experiments have been published by Mr. Siebold in 1797, in his Treatise on the Salivary System.

Saliva is a limpid fluid like water; but much more viscid: it has neither smell nor taste. Its specific gravity, according to Hamberger, is 1.0167; according to Siebold, 1.080. When agitated, it froths like all other adhesive liquids; indeed it is usually mixed with air, and has the appearance of froth.

It neither mixes readily with water nor oil; but by trituration in a mortar it may be so mixed with water as to pass through a filtre. It has a great affinity for oxygen, absorbs it readily from the air, and gives it out again to other bodies. Hence the reason why gold or silver, triturated with saliva in a mortar, is oxidized, as Du Tennetar has observed; and why the killing of mercury by oils is much facilitated by spitting into the mixture. Hence also, in all probability, the reason that saliva is a useful application to sores of the skin. Dogs, and several other animals, have constantly recourse to this remedy, and with much advantage.

When boiled in water, a few flakes of albumen precipitate. When evaporated, it swells exceedingly, and leaves behind it a thin brown-coloured crust; but if the evaporation is conducted slowly, small cubic crystals of muriat of soda, (common salt) are formed; and when the evaporation is completed, there remains behind a substance which resembles vegetable gluten, and which takes fire on burning coals, exhaling the odour of prussic acid, and of burning feathers. The viscidity of saliva, the property which it has of absorbing oxygen, and of being inspissated, and this glutinous residuum, announce the presence of animal mucilage as a component part.

When saliva is distilled in a retort, it froths very much: 100 parts yield 80 parts of water nearly pure, then a little carbonat of ammonia, some oil, and an acid, which perhaps is the prussic. The residuum amounts to about 1.56 parts, and is composed of muriat of soda, phosphat of soda, and phosphat of lime.

When saliva is left exposed to the air, it absorbs a considerable portion of it, a slight pellicle appears on its surface, it becomes muddy, and deposits some flakes, exhaling at the same time a strong ammoniacal odour. Soon after it putrefies, and becomes exceedingly fetid.

The acids and alcohol inspissates saliva; the alkalies disengage ammonia; oxalic acid precipitates lime; and the nitrats of lead, mercury, and silver, precipitate phosphoric and muriatic acids.

From these facts, it follows that saliva, besides water, which constitutes at least four-fifths of its bulk, contains the following ingredients:

1. Mucilage,	4. Phosphat of soda,
2. Albumen,	5. Phosphat of lime,
3. Muriat of soda,	6. Phosphat of ammonia.

But it cannot be doubted that, like all the other animal fluids, it is liable to many changes from disease, &c. Brugnatelli found the saliva of a patient, labouring under an obstinate venereal disease, impregnated with oxalic acid.

The concretions which sometimes form in the salivary ducts, &c. and the tartar or bony crust which so often attaches itself to the teeth, are composed of phosphat of lime.

Such are the properties of human saliva. The saliva of the horse was analysed by Hapel Delachenier in 1780. He collected 12 ounces of it in the space of 24 hours by puncturing the salivary duct. Its colour was greenish-yellow; its feel soapy; it had a weak disagreeable smell, and a saline taste. Boiling water and alcohol coagulated it in part; as did the acids. When sulphuric acid was used, sulphat of soda was obtained. It putrefied in about 14 days; and when allowed to evaporate spontaneously, it left a black residuum like earth. When distilled, it yielded an insipid watery liquid, crystals of carbonat of ammonia, a thick black empyreumatic oil, carbureted hydrogen, and carbonic acid; and a charcoal remained.

It is rather surprising that no experiments have been hitherto made on the saliva of dogs; though the hydrophobia has been usually ascribed to the infusion of the saliva of that animal rendered morbid by disease.

SALIVATION. See MEDICINE.

SALIX, the *willow*, a genus of the diandria order, in the diœcia class of plants, and in the natural method ranking under the 50th order, amentaceæ. The amentum of the male is scaly; there is no corolla; but a nectariferous glandule at the base of the flower. The female amentum is scaly; there is no corolla; the style bifid; the capsule unilocular and bivalved; the seeds pappous. There are 53 species, of which the most remarkable are,

1. The caprea, or common sallow-tree, grows to but a moderate height, having smooth, dark-green, brittle branches; oval, waved, rough leaves, indented at top, and woolly underneath. It grows abundantly in this country, but more frequently in dry than moist situations. It is of a brittle nature, so is unfit for the basket-makers; but will serve for poles, stakes, and to lop for fire-wood; and its timber is good for many purposes.

2. The alba, white, or silver-leaved willow, grows to a great height and considerable bulk, having smooth, pale-green shoots; long, spear-shaped, acuminated, sawed, silvery-white leaves, being downy on both sides, with glands below the serratures. This is the common white willow, which grows abundantly about towns and villages, and by the sides of rivers and brooks, &c.

3. The vitellina, yellow or golden willow, grows but to a moderate height, having yellow, very pliant shoots; oval, acute, serrated, very smooth leaves, with the serratures cartilaginous, and with callous punctures on the footstalks.

4. The purpurea, purple or red willow, grows to a large height, having long, reddish, very pliable shoots, and long, spear-shaped, serrated, smooth leaves, the lower ones being opposite.

5. The viminalis, or osier-willow, grows but a moderate height, having slender rod-like branches; very long, pliant, greenish shoots; and very long, narrow, spear-shaped, acute, almost entire leaves, hoary, and silky underneath.

6. The pentandra, pentandrous, broad-leaved, sweet-scented willow, grows to some considerable stature, having brownish-green branches; oblong, broad, serrated, smooth, sweet-scented leaves, shining above; and pentandrous flowers.

7. The triandria, or triandrous willow, grows to a large stature, having numerous, erect, greyish-green branches, and pliant shoots; oblong, acute-pointed, serrated, smooth, shining-green leaves, eared at the base; and triandrous flowers.

8. The fragilis, fragile or crack willow, rises to a middling stature, with brownish, very fragile, or brittle branches, long, oval-lanceolate, sawed, smooth leaves of a shining green on both sides, having dentated glandular footstalks. This sort in particular being exceedingly fragile, so that it easily cracks and breaks, is unfit for culture in osier-grounds.

9. The Babylonica, Babylonian pendulous salix, commonly called weeping willow, grows to a largish size, having numerous, long, slender, pendulous branches, hanging down loosely all round in a curious manner, and long, narrow, spear-shaped, serrated, smooth leaves. This curious willow is a native of the East.

All the species of salix are of the tree kind, very hardy, remarkably fast growers, and several of them attaining a considerable stature when permitted to run up to standards. They are mostly of the aquatic tribe, being generally the most abundant, and of most prosperous growth, in watery situations; they, however, will grow freely almost any where, in any common soil and exposure; but grow considerably the fastest and strongest in low moist land, particularly in marshy situations, by the verges of rivers, brooks, and other waters; likewise along the sides of watery ditches, &c. which places often lying waste, may be employed to good advantage in plantations of willows for different purposes.

SALMASIA, a genus of the pentandria trigynia class and order. The calyx is five-parted; corolla five-petalled; style none; capsule three-celled, three-valved, many-seeded. There is one species, a shrub of Guinea.

SALMO, *salmon*, a genus of fishes of the order abdominales. The generic character is, head smooth, compressed; tongue cartilaginous; teeth both in the jaws and on the tongue; gill-membrane from four to ten rayed; body compressed, furnished at the hind part with an adipose fin.

1. Salmo salar, the common salmon, so highly esteemed for the delicacy of its flavour, and so important an article in a commercial

view, is chiefly an inhabitant of the northern regions, where it occurs at different periods both in salt and fresh waters; quitting the sea at certain seasons to deposit its spawn in the gravelly beds of rivers, at a great distance from their mouths. In order to arrive at the spots proper for this purpose, there are scarcely any obstacles which the fish will not surmount. They will ascend rivers for hundreds of miles; force themselves against the most rapid streams, and spring with amazing agility over cataracts of several feet in height. They are taken, according to Mr. Pennant, in the Rhine as high as Basil; they gain the sources of the Lapland rivers, in spite of their torrent-like currents; they surpass the perpendicular falls of Leixlip, Kennerth, and Pont Aberglastyn. At the latter of these places, Mr. Pennant assures us that he has himself witnessed the efforts of the salmon, and seen scores of fish, some of which succeeded, while others miscarried in the attempt during the time of his observation. It may be added, that the salmon, like the swallow, is said to return each season to the self-same spot to deposit its spawn. This has been ascertained by the experiments of Monsr. De la Lande, who fastening a small ring of copper to the tails of some individuals, and then setting them at liberty, found that some of them made their appearance in the same place for three succeeding seasons. The experiment of fastening gold or silver rings to salmon is said by Dr. Bloch to have been occasionally practised by some of the Eastern princes, and it is added that by this method a communication has been proved between the Caspian and Northern seas and the Persian Gulf.

The general history of the salmon-fishery on the river Tweed, is amply detailed by Mr. Pennant. "At the latter end of the year, or in the month of November, the salmon begin to press up the river as far as they can reach, in order to spawn. When that time approaches they seek for a place fit for the purpose; the male and female unite in forming a proper receptacle for it in the sand or gravel, about the depth of 18 inches. In this the female deposits the spawn, which they afterwards cover carefully up by means of their tails, which are observed to have no skin on them for some time after this period. The spawn lies buried till spring, if not disturbed by violent floods, but the salmon hasten to the sea as soon as they are able, in order to recover their strength; for after spawning they are observed to become very lean, and are then called by the name of kippers. When the salmon first enter the rivers they are observed to have a great many small animals adhering to them, especially about the gills: these are the lernææ salmoneæ of Linnæus, and are signs that the fish is in high season: soon after the salmon have left the sea, the lernææ die, and drop off. About the latter end of March the spawn begins to exclude the young, which gradually increase to the length of four or five inches, and are then called smelts or smouts. About the beginning of May, the river is full of them; it seems to be all alive; and there is no having an idea of their numbers without seeing them; but a seasonable flood then hurries them all to sea, scarcely any or very few of them being left in the river. About the middle of June the earliest of the fry begin to drop into the river again from the sea, at that time about twelve, fourteen, or sixteen inches in length, and by a gradual progress, increase in number and size, till about the end of July, which is at Berwick termed the gilse time (the name given to the fish at that age). At the end of July, or the beginning of August, they lessen in number, but increase in size, some being six, seven, eight, or nine pounds weight. This appears to be a surprising growth; yet we have received from a gentleman at Warrington an instance still more so. A salmon weighing seven pounds three quarters, taken on the seventh of February, being marked with scissars on the back fin and tail, and turned into the river, was again taken on the 17th of the following March, and then found to weigh seventeen pounds and a half.

"All fishermen agree that they never find any food in the stomach of this fish. Perhaps during the spawning-time, they may entirely neglect their food, as the phocæ, called sea-lions and sea-bears, are known to do for months together during the breeding-season; and it may be that, like those animals, the salmon return to sea lank and lean, and come from it in good condition. It is evident that at times their food is both fish and worms, for the angler uses both with good success, as well as a large gaudy artificial fly, which the fish probably mistakes for a gay libellula or dragon-fly. The capture about the Tweed is prodigious in a good fishery. Some few years ago there were above seven hundred fish taken at one hawl, but from fifty to a hundred is very frequent." See FISHERY, Vol. 1, p. 736.

The general length of the salmon is from two and a half to three feet, but sometimes much more. The male is principally distinguished by the curvature of the jaws; both the upper and lower mandible bending towards each other more or less in different individuals, and at different seasons. The general colour of both sexes is a silvery grey, of a much darker cast on the back; the sides of the male are marked with numerous, small, irregular, dusky, and copper-coloured spots, while those of the female exhibit only several rather large, distant, roundish, or somewhat lunated spots of a dark colour. Exclusive of these differences, the male is of a somewhat longer or more slender shape than the female. The scales in the salmon are middle-sized, and not very strongly adherent.

In the intestinal canal of the salmon is often found a species of tænia, or tape-worm, of about three feet in length. Dr. Bloch informs us that in a salmon which had been three weeks dead, he found one of those worms still living. See Plate Nat. Hist. fig. 349.

2. Salmo trutta, salmon-trout, greatly allied in point of general appearance to the salmon, but rarely of equal size; colour purplish or violet, with the head and whole body pretty thickly marked with rather small round dark or blackish spots, surrounded by a paler circle; scales rather small. Native of the European seas, passing, like the salmon, into rivers to deposit its spawn; is of equal delicacy with the salmon, and the flesh of similar colour; varies occasionally both in colour and spots, which are sometimes rather angular than round; possesses a considerable degree of phosphoric quality, which seems to reside in the viscid mucus covering the skin. Like the salmon, this fish is prepared in different methods for sale, being sold both fresh and salted, as well as smoked, pickled, &c. &c.

3. Salmo fario, common trout. The trout is an inhabitant of clear and cold streams and lakes in most parts of Europe, and admits of considerable variety as to the tinge both of its ground-colour and spots. Its general length is from six to fifteen or sixteen inches, and its colour yellowish-grey, darker or browner on the back, and marked on the sides by several rather distant, round, bright-red spots, each surrounded by a tinge of pale-blue grey. Sometimes the ground-colour of the body is a purplish grey; the red spots much larger, more or less mixed with black, and the belly of a white or silvery cast; the fins are of a pale purplish brown; the dorsal fin marked with several darker spots; the head is rather larger in proportion than that of the salmon, the scales small, and the lateral line straight. The female fish is of a brighter and more beautiful appearance than the male.

Mr. Pennant informs us that in the lake Llyndivi in South Wales are trouts marked with red and black spots as large as sixpences; and others unspotted and of a reddish hue, sometimes weighing near ten pounds; but these latter are said to be bad-tasted.

In general the trout prefers clear, cold, and briskly-running waters, with a stony or gravelly bottom. It swims with rapidity, and, like the salmon, springs occasionally to a very considerable height in order to surmount any obstacle in its course. It lives on worms, small fishes, shell-fish, and aquatic insects, and is particularly delighted with May-flies (ephemeræ), as well as with phryganeæ, gnats, and their larvæ. It generally spawns in September, or in the colder parts of Europe, in October, and at those times gets among the roots of trees, stones, &c. in order to deposit its eggs, which are observed to be far less numerous than those of other river-fish. Yet the trout, as Bloch observes, is a fish that admits of very considerable increase; owing, no doubt, to the circumstance of most of the voracious kind of fishes avoiding waters of so cold a nature as those which trouts delight to inhabit; and their increase would be still greater, were they not themselves of a voracious disposition, frequently preying even on each other.

The merit of the trout as an article of food is too well known to require particular notice. In this respect, however, as in other fishes, those are most esteemed which are natives of the clearest waters.

The stomach of this fish is uncommonly strong and thick; but this circumstance is observed to be no where so remarkable as in those found in some of the Irish lakes, and particularly in those of the county of Galway. These are called gillaroo trouts; on the most accurate examination, however, it does not appear that they are specifically different from the common trout; but by living much on shell-fish, and swallowing small stones at the same time, their stomachs acquire a much greater degree of thickness, and a kind of muscular appearance, so as to resemble a sort of gizzard.

Mr. Pennant observes, that it is a matter of surprise that the trout, though so common a fish, should appear to be unnoticed by the antients, except Ausonius, who is supposed to have intended it by the name of salar. He mentions it, however, merely on account of its beauty, and without any thing relative to its merit as a food.

4. Salmo salmulus. The samlet is, according to Pennant, the least of the British species of this genus, and is frequently seen in the river Wye, in the upper part of the Severn, and in the rivers that run into it, in the north of England, and in Wales. It is by several imagined to be the fry of the salmon; but Mr. Pennant dissents from this opinion for the following reasons: first, it is well known that the salmon-fry never continue in fresh water the whole year, but, as numerous as they appear on their first escape from the spawn, all vanish on the first vernal flood that happens, which sweeps them into the sea, and leaves scarcely one behind; secondly, the growth of salmon-fry is so quick and so considerable as suddenly to exceed the bulk of the largest samlet; for example, the fry that have quitted the fresh water in spring, not larger than gudgeons, return into it again a foot or more in length; thirdly, the salmon obtains a considerable bulk before it begins to breed; the samlets, on the contrary, are found both male and female of their common size, and are readily distinguished by being furnished with either the hard or soft roe; fourthly, they are found in the fresh waters all times of the year, and even at seasons when the salmon-fry have gained a considerable size. It is well known that at Shrewsbury (where they are called Samsons), they are found in such quantities in the month of September, that a skilful angler, in a coracle, will take with a fly from twelve to sixteen dozen in a day. They spawn in November and December, at which time those of the Severn push up towards the head of that river, quitting the smaller brooks, and return into them again when they have done spawning. They have a general resemblance to the trout, and must therefore be described comparatively.

The head is proportionally narrower, and the mouth smaller; the body deeper; the length seldom more than six or seven inches, or at most about eight and a half; the pectoral fins have generally but one large black spot, though sometimes a single small one attends it; whereas the pectoral fins of the trout are more numerously marked; the spurious or fat fin on the back is never tipped with red, nor is the edge of the anal fin white; the spots on the body are fewer, and not so bright; the body is also marked from back to sides with six or seven large blueish bars; but this Mr. Pennant allows to be not a certain character, as the same is sometimes observed in young trouts; lastly, the tail of the samlet is much more forked than that of the trout. The samlet is very frequent in the rivers of Scotland, where it is called the parr. It is also common in the Wye, and is there known by the title of skirling or laspring.

5. Salmo salvelinus, salvelin trout. Length about twelve inches; shape resembling that of the salmon, but rather more slender; colour of the back dark-brownish blue; of the sides silvery, marked with pretty numerous, moderately distant, small, round, red spots, which are sometimes surrounded with a pale margin; belly red or orange-colour; pectoral, ventral, and anal fins the same, but with the two first rays white; dorsal and caudal fin blueish brown; adipose fin small, pale, and tipped with brown; scales rather small than large; lateral line strait; tail moderately bifurcated; both jaws of equal length; irides silvery. Native of mountainous lakes in several parts of Germany, and of several of the rivers in Siberia, and (if this species is the red charr of the English) in some of the lakes of our own country, as those of Westmoreland, &c. As in others of this genus, those which inhabit the clearest and coldest waters are observed to be of the richest colours. It is a fish of great delicacy of flavour, and much esteemed as a food.

6. Salmo eperlanus, smelt. Of this species there appear to be two varieties: one not exceeding the length of three or four inches; the other arriving at the general length of six, eight, or nine inches, and sometimes even to twelve or thirteen. The larger variety seems to be that so frequently seen about the British coasts, and which is distinguished by Dr. Bloch under the name of eperlano-marinus, or sea-smelt. These fishes are found about our coasts throughout the whole year, and rarely go to any great distance from the shores, except when they ascend rivers either at or some time before the spawning-season. It is observed by Mr. Pennant that in the river Thames and in the Dee, they are taken in great abundance in November, December, and January; but in other rivers not till February, spawning in the months of March and April. The smelt is a very elegant fish; its form beautifully taper; the skin thin, and the whole body, but particularly the head, semitransparent; the colour of the back is whitish, with a cast of green, beneath which it is varied with blue, and then succeeds the beautiful silvery gloss of the abdomen; the scales are small, and easily rubbed off; the eyes are silvery; the under jaw longer than the upper; in front of the upper are four large teeth, those in the sides of the jaws being small; the tail is forked. This fish is an inhabitant of the European seas; it has generally a peculiar odour, which in those of British growth is commonly compared to that of a cucumber, but by some to that of a violet.

7. Salmo Groenlandicus, Greenland salmon. Length about seven inches, which it very rarely exceeds; shape lengthened, contracting somewhat suddenly towards the tail; dorsal fin placed in the middle of the back; fins rather large for the size of the fish; scales small; tail forked; colour pale-green, with a tinge of brown above; abdomen and sides silvery; in the male fish, just above the lateral line, is a rough fascia, beset with minute pyramidal scales standing upright like the pile of a shag. The use of this villous line is highly singular, since it is affirmed that while the fish is swimming, and even when thrown on shore, two, three, or even as many as ten will adhere, as if glued together, by means of this pile, insomuch that if one is taken, the rest are also taken up at the same time. This species swarms off the coasts of Greenland, Iceland, and Newfoundland, and is said to be one of the chief supports of the Greenlanders, and a sort of dessert at their most delicate repasts. The inhabitants of Iceland are said to dry great quantities of it, in order so serve as a winter food for their cattle, whose flesh is apt to acquire an oily flavour in consequence. This fish lives at sea the greatest part of the year; but in April, May, June, and July, comes in incredible shoals into the bays, where immense multitudes are taken in nets, and afterwards dried on the rocks. When fresh they are by some said to have the smell of a cucumber, though others affirm that the scent is highly unpleasant. They feed on small crabs and other marine insects, as well as on the smaller fuci and confervæ, on which they are also observed to deposit their ova.

8. Salmo thymallus, grayling salmon. This elegant species grows to the length of about eighteen inches, and is an inhabitant of the clearer and colder kind of rivers in many parts of Europe and Asia, particularly such as flow through mountainous countries. In England it is found in the rivers of Derbyshire; in some of those of the North; in the Tame near Ludlow; in the Lug and other streams near Leominster; and in the river near Christchurch in Hampshire. In Lapland it is said to be very common, where the natives make use of its intestines instead of rennet, in preparing the cheese which they make from the milk of the rein-deer.

The shape of the grayling resembles that of the trout, but is rather more slender; its colour is a beautiful silvery grey, with numerous longitudinal deeper stripes, disposed according to the rows of scales, which are of a moderately large size; the head, lower fins, and tail, are of a brownish or rufous cast; the dorsal fin, which is deeper and broader than in the rest of the genus, is of a pale violet-colour, crossed by several dusky bars; the adipose fin is very small, and the tail forked. The largest English grayling recorded by Mr. Pennant was taken at Ludlow, and measured above half a yard in length, its weight being four pounds eight ounces; the general size of the British specimens being far short of this measure.

The grayling, says Mr. Pennant, is a voracious fish, rising freely to the fly, and will very eagerly take a bait; it is a very swift swimmer, disappearing like the transient passage of a shadow, from whence perhaps is derived its antient name of umbra. It is said to be a fish of very quick growth, feeding on water-insects, the smaller kind of testacea, and the roe of other fishes, as well as on the smaller fishes themselves; its stomach is so strong as to feel almost cartilaginous. It spawns in April and May, the full-grown ova being nearly of the size of peas. The grayling is much esteemed for the delicacy of its flesh, which is white, firm, and of a fine flavour, and is considered as in the highest season in the depth of winter.

SALON, or Saloon, in architecture, a very lofty spacious hall, vaulted at top, and sometimes comprehending two stories or ranges of windows.

SALOP, or Salep. See Starch.

SALPA, a genus of insects of the order mollusca. Body loose, nayant, gelatinous, tubular, and open at each extremity; intestines obliquely placed. The animals of this genus are of a gregarious nature, and often adhere together; they swim with great facility, and possess the power of contracting and opening at pleasure. There are two divisions: A is furnished with an appendage which differs in the several species; B without the terminal appendage.

SALSOLA, *saltwort, kali, &c.* a genus of the class and order pentandria digynia, and in the natural method ranking under the 12th order, holoraceæ. The calyx is pentaphyllous; there is no corolla; the capsule is monospermous, with a screwed seed. The species are 31, of which the principal are:

1. Salsola kali grows naturally in the salt marshes in divers parts of England. It is an annual plant, which rises above five or six inches high, sending out many side branches, which spread on every side, with short awl-shaped leaves, which are fleshy, and terminate in acute spines.

2. Salsola rosacea grows naturally in Tartary. This is an annual plant, whose stalks are herbaceous, and seldom rise more than five or six inches high.

3. Salsola soda rises with herbaceous stalks near three feet high, spreading wide. The leaves on the principal stalk, and those on the lower part of the branches, are long, slender, and have no spines; those on the upper part of the stalk and branches are slender, short, and crooked. All the sorts of glass-wort are sometimes promiscuously used for making soda or mineral alkali, but this species is esteemed best. The manner of making it is as follows: Having dug a trench near the sea, they place laths across it, on which they lay the herbs in heaps, and, having made a fire below, the liquor which runs out of the herbs drops to the bottom, which at length thickening, becomes soda, which is partly of a black, and partly of an ash-colour, very sharp and corrosive, and of a saltish taste. This, when thoroughly hardened, becomes like a stone, and in that state is transported to different countries for the making of glass, soap, &c.

4. Salsola tragus grows naturally on the sandy shores of the south of France, Spain, and Italy. This is also an annual plant, which sends out many diffused stalks, with linear leaves an inch long, ending with sharp spines.

5. Salsola vermiculata grows naturally in Spain. This has shrubby perennial stalks, which rise three or four feet high, sending out many side branches, with fleshy, oval, acute-pointed leaves, coming out in clusters from the side of the branches; they are hoary, and have stiff prickles See SODA.

SALT, *common*. The preparation of that kind of salt which is used for culinary and economical purposes (muriat of soda) depends upon the well-known fact, that the salt contained in the sea-water, or brine-springs, being a fixed body, will not rise with the vapour of the water. All, therefore, that is wanted, is to expose any water containing salt to evaporation. The salt commonly known by the name of bay-salt is obtained from the water of the sea by evaporation. This evaporation is in some places performed by the heat of the sun, the water being let into shallow trenches, in order to expose as large a surface as possible. This method is practised in the southern provinces of France, and on a very large scale near Aveiro in Portugal. In the northern countries, where the heat of the sun is not sufficiently great, artificial fires are employed. In some salt-works these two methods are united; and in England, and countries where salt-rock is plentiful, that substance is dissolved in salt water, and then evaporated. In very cold countries another method is employed to separate the salt from sea-water. The water is exposed in trenches on the sea-shore, where it forms so thin a stratum, that the cold of the atmosphere acts powerfully in congealing it. As the frozen part consists of mere water, the fluid which remains is consequently more concentrated. The operation is then completed by means of artificial heat.

The most convenient works for making salt from brine by boiling are constructed in the following manner: The saltern, or boiling-house, is erected near the sea-shore, and is furnished with a furnace and one or two large pans, which are commonly made of iron plates, joined together with nails, and the joints filled with a strong cement; and the bottom of the pans is prevented from bending down, by being supported by strong iron bars.

The salt-pan being filled with sea-water, a strong fire of pit-coal is lighted in the furnace; and then, for a pan which contains about 1400 gallons, the salt-boiler takes the whites of three eggs, and incorporates them all with two or three gallons of sea-water, which he pours into the salt-pan, while the water contained therein is only lukewarm, and mixes this with the rest by stirring it about with a rake. In many places they use, instead of eggs, the blood of sheep or oxen to clarify the sea-water: and in Scotland they do not give themselves the trouble to clarify it at all. As the water heats, there arises a black frothy scum upon it, which is to be taken off with wooden skimmers. After this the water appears perfectly clear, and by boiling it briskly about four hours, a pan loaded in the common way, that is, about fifteen inches deep, will begin to form crystals upon its surface. The pan is then filled up a second time with fresh sea-water; and about the time when it is half-filled, the scratch-pans are taken out and emptied of a white powder, seeming a kind of calcareous earth, which separates itself from the sea-water, during its boiling, before the salt begins to shoot. When these have been emptied, they are again put into their places, where they are afterwards filled again. This powder being violently agitated by the boiling liquor, does not subside till it comes to the corners of the pan, where the motion of the mass is smaller, and it there falls into these pans placed on purpose to receive it.

The second filling of the pan is boiled down after clarifying in the same manner as the first, and so a third and a fourth; but in the evaporation of the fourth, when the crystals begin to form themselves, they slacken the fire, and only keep the liquor simmering. In this heat they keep it all the while that the salt is granulating, which is nine or ten hours. The granules, or crystals, all fall to the bottom of the pan; and when the water is almost all evaporated, and the salt lies nearly dry at the bottom, they rake it all together into a long heap on one side of the pan, where it lies a while to drain from the brine, and then is put into barrows, and carried to the storehouse, and delivered into the custody of his majesty's officers. In this manner the whole process is usually performed in 24 hours, the salt being commonly drawn out every morning. This is the method in most of our salt-works; but in some they fill the pan seven times before they boil up the salt, and so take it out but once in two days, or five times in a fortnight. In the common way of four boilings, from a pan of the usual size, containing 1300 gallons, they draw from fifteen to twenty bushels of salt every day, each bushel weighing fifty-six pounds.

When the salt is carried into the storehouse, it is put into brabs, which are partitions, like stalls for horses, lined at three sides, and the bottom with boards, and having a sliding-board on the foreside to draw up on occasion. The bottoms are made shelving, being highest at the back, and gradually inclining forward; by this means the brine remaining among the salt, easily separates and runs from it, and the salt in three or four days becomes sufficiently dry; in some places they use cribs and barrows, which are long and conic wicker-baskets, for this purpose; and in some places wooden troughs, with holes in the bottom. The saline liquor which remains from the making of salt is what is called bittern, from which Epsom salt or muriat of magnesia is often extracted.

Much in the same manner is the salt obtained from the brine of salt-springs, pits, &c. White salt is prepared from sea-water, or any other kind of salt-water, first heightened into a strong brine by the heat of the sun, and the operation of the air. It may also be prepared from a strong brine, or lixivium, drawn from earths, stones, or sands, strongly impregnated with common salt. Refined rock-salt is that obtained by dissolving fossil or rock-salt in salt or fresh water, and afterwards boiling the solution.

A great quantity of rock-salt is used at Northwich, in order to strengthen their brine-springs; and a much greater quantity is sent coastwise to Liverpool, and other places, where it is either used for strengthening brine-springs or sea-water; much of this rock-salt was formerly exported to Holland, and it is still sent to Ireland for the same purpose.

The Northwich rock-salt is never used at our tables in its crude state; and its application to the pickling or curing of flesh or fish, or preserving any provisions, without its being previously refined into white salt, that is, without its being dissolved in water, and boiled down in what is called white-salt, is prohibited under a penalty of 40*s*. for every pound of rock-salt so applied. The pure transparent masses, however, of rock-salt, might probably be used by us with our food, without any sort of danger or inconvenience; at least we know that rock-salt is so used, without being refined, both in Poland and in Spain.

The quantity of rock-salt which may be dissolved in a definite quantity, suppose a pint of 16 avoirdupois ounces of water, is differently estimated by different authors. Boerhaave is of opinion that 16 ounces of water will not dissolve quite five ounces of rock-salt; Spielmann thinks that they will dissolve $6\frac{2}{3}$ ounces; Newman agrees with Spielman; Eller says, that seven ounces of fossil salt may be dissolved in 16 ounces of water; lastly, Hoffmann assures us, that 16 ounces of water will not dissolve above six ounces of common salt. It is not wholly improbable, that different sorts of rock-salt may differ somewhat with respect to their solubility in water.

If it is admitted, that 16 ounces of water can dissolve six ounces of salt and no more, then we may be certain, that no brine-spring in any part of the world, can yield six ounces of salt from a pint of the brine. For brine springs are, ordinarily, nothing but water in which fossil salt has been dissolved; but a pint of the strongest brine cannot contain so much salt as is contained in a pint of water, which has been saturated with six ounces of salt; for a pint of water, in which six ounces of salt have been dissolved, is increased a little in bulk; it will do more than fill a pint-measure, and the salt left in the surplus will shew how much the salt contained in a pint of the strongest brine falls short of six ounces. Or we may consider the matter in the following manner, which will perhaps be more intelligible; 16 ounces of water, impregnated with six ounces of salt, constitute a saturated brine, weighing 22 ounces; if therefore we would know how much salt is contained in 16 ounces of such brine, by the rule of proportion we may argue, that if 22 ounces of brine contain six ounces of salt, 16 ounces of brine will contain $4\frac{4}{11}$ ounces of salt. Hence we may infer, that the strongest brine-springs will not yield much above one quarter of their weight of salt.

There are a great many brine-springs in Cheshire, in Worcestershire, Staffordshire, Hampshire, and in other parts of Great Britain; some of which are sufficiently rich in salt to be wrought with profit, others not. From what has been before advanced, the reader will readily comprehend that 16 tons of the strongest brine consist of 12 tons of water, and of four tons of salt; and that, in order to obtain these four tons of salt, the 12 tons of water must be, by some means or other, evaporated, so as to leave the salt in a concrete form. Suppose there should be a brine, which in 16 tons should contain 15 tons of water, and only one ton of salt; yet it may chance, that such a weak brine may be wrought with more profit than the strongest; for the profit arising from the boiling of brine into salt, depends as much upon the price of the fuel used in boiling it, as upon the quantity of salt which it yields. Thus the sea-water, which surrounds the coasts of Great Britain, is said to hold seldom more than one-thirtieth, or less than one-fiftieth part of common salt; but fuel is so cheap at Newcastle, that they can evaporate thirty or forty tons of water, in order to obtain one ton of salt, and yet gain as much clear profit as those do, who, in countries less favourably situated for fuel, boil down the strongest brine.

The advantage resulting from strengthening weak brine or sea-water, by means of rock-salt, is very obvious. Suppose that the sea-water at Liverpool, where large quantities of rock-salt are refined, would yield one ton of salt from 48 tons of water; then must a quantity of fuel sufficient to evaporate 47 tons of water be used, in order to obtain one ton of salt. But if as much rock-salt is put into the forty-eight tons of sea-water; as can be dissolved in it, then will the sea-water resemble a brine fully saturated, each 16 tons of which will give four tons of salt, and the whole quantity yielded by the evaporation of 47 tons of water will be 12 tons of salt.

SALTS. The word salt was originally confined to muriat of soda, or common salt, a substance which has been known, and in common used, from the remotest ages. It was afterwards generalized by chemists, and employed by them in a very extensive and not very definite sense. Every body which is sapid, easily melted, soluble in water, and not combustible, has been called a salt.

Salts, were considered by the older chemists as a class of bodies intermediate between earths and water. Many disputes arose about what bodies ought to be comprehended under this class, and what ought to be excluded from it. Acids and alkalies were allowed by all to be salts; but the difficulty was to determine concerning earths and metals; for several of the earths possess all the properties which have been ascribed to salts, and the metals are capable of entering into combinations which possess saline properties.

In process of time, however, the term salt was restricted to three classes of bodies, viz. acids, alkalies, and the compounds which acids form with alkalies, earths, and metallic oxides. The first two of these classes were called simple salts; the salts belonging to the third class were called compound or neutral. This last appellation originated from an opinion long entertained by chemists, that acids and alkalies, of which they are composed, were of a contrary nature, and that they counteracted one another; so that the resulting compounds possessed neither the properties of acids nor of alkalies, but properties intermediate between the two.

Chemists have lately restricted the term salt still more, by tacitly excluding acids and alkalies from the class of salts altogether. At present, then, it denotes *only the compounds formed by the combination of acids with alkalies, earths, and metallic oxides.*

No part of chemistry has been cultivated with more zeal than the salts, especially for these last 40 years. During that time the number of saline bodies has been enormously increased, and the properties of a very great number have been determined with precision. Still, however, this wide and important region is far from being completely explored.

Chemists have agreed to denominate the salts from the acids which they contain. The earth, alkali, and metallic oxide, combined with that acid, is called the base of the salt. Thus common salt being a compound of muriatic acid and soda, is called a muriat; and soda, is called the base of common salt. Now since there are 32 acids and 57 bases, it would appear, at first sight, that there are 1824 salts; but of the 45 metallic oxides at present known, there are a considerable number which cannot combine with many of the acids. This is the case also with silica, and perhaps with some of the other earths. We must therefore subtract all these from the full number 1824. To compensate, however, this deficiency, at least in part, there are several acids capable of combining with two bases at once. Thus the tartaric acid combines at once with potass and soda. Such combinations are called triple salts, and they increase the number of salts considerably. There are some salts, too, which are capable of combining with an additional dose of their acid, and others which combine with an additional dose of their base. The French chemists denote the first of these combinations by adding to the usual name of the salt the phrase with excess of acid, or by prefixing it to the word acidulous: they denote the second by subjoining the phrase with excess of base. This method of naming has the merit indeed of being precise, but it is exceedingly awkward, and intolerably tedious. The ingenious mode of naming these combinations proposed by Dr. Pearson ought certainly to be preferred. It is equally precise, if not more so, and far more convenient in every respect. It consists in prefixing to the usual name of the salt the preposition super, to denote an excess of acid, and the preposition sub to denote an excess of base. Thus sulphat of potass denotes the salt in its state of perfect neutralization, without any excess either of the sulphuric acid or of the potass; supersulphat of potass is the same salt with an excess of acid; subsulphat of potass is the same salt with excess of base. These three different kinds must increase the number of saline compounds very considerably; but the precise number of salts is not known, as many of them remain still unexamined by chemists. Probably they are not much fewer than 2000. Some idea may be formed of the progress which this branch of chemistry has made, by recollecting that 40 years ago not more than 30 salts in all were known.

Of these 2000, however, a considerable number may be considered as still unknown, as they have been merely formed without being examined. Of those which are known, the greater number have not been applied to any use, and therefore do not deserve a very particular description.

As the different genera of salts are denominated from their acids, it is evident that there are as many genera as there are acids. The terminations of the names of these genera differ according to the nature of the acids which constitute them. When that acid contains a maximum of oxygen, the termination of the genius is *at*; when it does not contain a maximum of oxygen, the termination of the genus is *ite*. Thus the salts which contain sulphuric acid are called sulphats; those which contain sulphurous acid are called sulphites. This distinction is of some consequence, because the salts differ very much, according as the acid is saturated with oxygen or not. The *ites* are seldom permanent; when exposed to the air, they usually attract oxygen, and are converted into *ats*.

Every particular species of salt is distinguished by subjoining to the generic term the name of its base. Thus the salt composed of sulphuric acid and soda is called sulphat of soda. Triple salts are distinguished by subjoining the names of both the bases connected by hyphens. Thus the compound of tartaric acid, potass, and soda, is called tartrat of potass-and-soda.

The salts then naturally divide themselves into two grand classes; the first of which comprehends the alkaline and earthy salts, which derive their most important characters from their acids; the second comprehends the metalline salts, whose bases on the contrary stamp their most important properties.

Salts, or the combinations of alkalies with acids which exist in the mineral kingdom, constitute the following genera and species:

Genus I. Potass.

Sp. 1. Nitrat of potass.

Genus II. Soda.

Sp. 1. Carbonat of soda,
2. Sulphat of soda,
3. Muriat of soda,
4. Borax.

Genus III. Ammonia.

Sp. 1. Muriat of ammonia.

Genus I. *Salts of potass.*

Sp. 1. *Nitrat of potass.* This salt is found native, mixed with nitrat of lime, muriat of potass, and other impurities, encrusting the surface of the earth in different parts of India, the Cape of Good Hope, Peru, Spain, Molfetta, &c. It is most commonly in fine capillary crystals. Sometimes, though rarely, massive, or in six-sided prisms.

Its primitive form is a rectangular octahedron. It occurs sometimes in that form, but more frequently the apexes of the pyramids are truncated. But its most usual variety is a six-sided prism, terminated by six-sided pyramids. A specimen of native nitre from Molfetta, analysed by Klaproth, contained

44.55 nitrat of potass
25.45 sulphat of lime
30.40 carbonat of lime
0.20 muriat of potass

100.60

Genus II. *Salts of soda.*

Sp. 1. *Carbonat of soda.* This salt is found in Egypt on the surface of the earth, and on the margin of certain lakes which become dry during the summer. It has often the appearance of a rough dusty powder, of a grey colour and alkaline taste. It occurs in China, where it is called kien; near Tripoli, where it is denominated trona; and likewise in Hungary, Syria, Persia, and India.

It is said sometimes to have been observed in crystals. The primitive form is a rhomboidal octahedron; but the pyramids are usually truncated.

A specimen of this salt from Egypt was found by Klaproth to consist of

32.6 dry carbonat of soda
20.8 dry sulphat of soda
15.0 dry muriat of soda
31.6 water

100.0

A specimen of fibrous carbonat from the interior of Africa, yielded the same chemist

37.0 soda
38.0 carbonic acid
22.5 water
2.5 sulphat of soda

100.0

Sp. 2. *Sulphat of soda.* This salt is found in Austria, Hungary, Styria, Switzerland, and Siberia, always in the neighbourhood of a mineral spring. It occurs usually in the state of powder, sometimes massive, and even crystallized. Colour greyish, or yellowish white.

Sp. 3. *Muriat of soda.* Common salt is found in immense masses under the earth's surface in many countries, particularly in Poland, Hungary, England, &c. Near Cordova in Spain there is said to be a mountain of common salt 500 feet high, and nearly three miles in circumference. There are two varieties of native common salt distinguished by their texture.

1. Foliated. This variety is usually found in vast masses, and sometimes crystallized in cubes. Colour various shades of grey and of red. Internal lustre glassy. Texture foliated. Fragments cubic. Streak grey. Specific gravity 2.143. Taste salt.

2. Fibrous. Found in masses, strata, or stalactitic. Colour various shades of grey, blue, red. Texture fibrous; fibres delicately curved. Fragments angular.

Sp. 4. *Borax.* This mineral is found in different parts of Thibet, &c. It is usually mixed with foreign bodies; that of Persia is in large crystals, enclosed in a fatty matter. The primitive form of its crystals is a rectangular prism, but it occurs usually in six-sided prisms, whose edges are variously truncated. Its colour is greyish, yellowish, or greenish white. Fracture foliated or conchoidal. Refracts doubly. Taste sweet, and somewhat acrid.

Genus III. *Salts of ammonia.*

Sp. 1. *Muriat of ammonia.* This salt occurs near volcanoes, of which it is a product. It is found also in Persia. It is found usually in the state of powder in the middle of lava. Sometimes in mass, and even in very irregular crystals. Colour white, often with a shade of yellow or green. Very soft.

A specimen of this salt from Tartary yielded Klaproth,

97.5 muriat of ammonia
2.5 sulphat of ammonia

100.0

There is no necessity for entering any further in this article into the detail of the compound salts, as the reader will find them under the different heads of Acetites, Fluats, Gallats, Lactats, Malats, Mellats, Muriats, Nitrats, Nitrites, Phosphats, Phosphites, Sulphats, Sulphites; also under the different acids: and the metallic compounds under the respective metals. See also Chemistry.

SALVADORA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is quadrifid; there is no corolla; the berry is monospermous; and the seed covered with an antlus or loose coat. There are three species, herbs of China.

SALVAGE MONEY, a reward allowed by the civil and statute law for the saving of ships or goods from the danger of the seas, pirates, or enemies.

Where any ship is in danger of being stranded, or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and on its being preserved by their means, the persons assisting therein shall in thirty days after be paid a reasonable reward for the salvage, otherwise the ship or goods shall remain in the custody of the officers of the customs as a security for the same.

SALVIA, *sage*, a genus of the monogynia order, in the digynia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The corolla is unequal; and the filaments placed crosswise on a pedicle. The most remarkable species, out of 79, are,

1. The officinalis, or common large sage, which is cultivated in gardens, of which there are the following varieties: 1. The common green sage. 2. The wormwood sage. 3. The green sage with a variegated leaf. 4. The red sage. 5. The red sage with a variegated leaf. These are accidental variations, and therefore are not enumerated as species. The common sage grows naturally in the southern parts of Europe, but is here cultivated in gardens for use; but the variety with red or blackish leaves is the most common in the British gardens; and the wormwood sage is in greater plenty here than the common green-leaved sage, which is but in few gardens.

2. The tomentosa, generally titled balsamic sage by the gardeners. The stalks of this do not grow so upright as those of the common sage; they are very hairy, and divide into several branches; the flowers are of a pale blue, about the size of those of the common sort. This sage is preferred to all the others for making tea.

3. The auriculata, common sage of virtue, which is also well known in the gardens and markets. The leaves of this are narrower than those of the common sort; they are hoary, and some of them are indented on their edges towards the base, which indentures have the appearance of ears.

4. The pomifera, with spear-shaped oval entire leaves, grows naturally in Crete.

5. and 6. The coccinea and formosa, are beautiful hot-house plants, with scarlet flowers.

All the sorts of sage may be propagated by seeds, if they can be procured; but, as some of them do not perfect their seeds in this country, and most of the sorts, but especially the common kinds for use, are easily propagated by slips, it is not worth while to raise them from seeds.

SAMARA, a genus of the monogynia order, in the tetrandria class of plants. The calyx is quadripartite; the corolla tetrapetalous; the stamina immersed in the base of the petal; the stigma funnel-shaped. There are three species, trees of the Cape.

SAMARITANS, an antient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

SAMBUCUS, *elder*, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quinquepartite; the corolla quinquefid; the berry trispermous. The species are only five, and the most remarkable are,

1. The nigra, or common black elder, with a tree-stem, branching numerously into a large spreading head, twenty or thirty feet high, and large five-parted umbels of white flowers towards the ends of the branches, succeeded by bunches of black and other different-coloured berries, in the varieties; which are, common black-berried elder-tree, white-berried elder, green-berried elder, laciniated or parsley-leaved elder, having the folioles much laciniated, so as to resemble parsley-leaves, gold-striped-leaved elder, silver-striped elder, silver-dusted elder.

2. The racemosa, racemose red-berried elder. This is a resident of the mountainous parts of the south of Europe, and is retained in our gardens as a flowering shrub, having a

peculiar singularity in its oval-clustered flowers and berries.

3. The Canadensis, or Canada shrubby elder.

SAMIELS, the Arabian name of a hot wind, peculiar to the desert of Arabia. It blows over the desert in the months of July and August from the north-west quarter, and sometimes it continues with all its violence to the very gates of Bagdad, but never affects any body within the walls. Some years it does not blow at all, and in others it appears six, eight, or ten times, but seldom continues more than a few minutes at a time. It often passes with the apparent quickness of lightning. The Arabians and Persians, who are acquainted with the appearance of the sky at or near the time this wind rises, have warning of its approach by a thick haze, which appears like a cloud of dust arising out of the horizon; and they immediately upon this appearance throw themselves with their faces to the ground, and continue in that position till the wind is passed, which frequently happens almost instantaneously; but if, on the contrary, they are not careful or brisk enough to take this precaution, which is sometimes the case, and they get the full force of the wind, it is instant death.

The above method is the only one which they take to avoid the effects of this fatal blast; and when it is over, they get up and look round them for their companions; and if they see any one lying motionless, they take hold of an arm or leg, and pull and jerk it with some force; and if the limb thus agitated separates from the body, it is a certain sign that the wind has had its full effect; but if, on the contrary, the arm or leg does not come away, it is a sure sign there is life remaining, although to every outward appearance the person is dead; and in that case they immediately cover him or them with clothes, and administer some warm diluting liquor to cause a perspiration, which is certainly but slowly brought about.

The Arabs themselves can say little or nothing about the nature of this wind, only that it always leaves behind it a very strong sulphureous smell, and that the air at these times is quite clear, except about the horizon, in the north-west quarter, before observed, which gives warning of its approach. We have not been able to learn whether the dead bodies are scorched or dissolved into a kind of gelatinous substance; but from the stories current about them, there has been frequent reason to believe the latter; and in that case such fatal effects may be attributed rather to a noxious vapour than to an absolute and excessive heat. The story of its going to the gates of Bagdad and no further, may be reasonably enough accounted for, if the effects are attributed to a poisonous vapour, and not an excessive heat.

SAMOLUS, *water pimpenal*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 21st order, preciæ. The corolla is salver-shaped, the stamina surrounded by small scales at its throat. The capsule is unilocular, inferior. There is one species.

SAMPSEANS, in church history, an antient sect, who were properly neither Jews, Christians, nor Gentiles, though they took their name from the Hebrew word *semes*, sun, as though they worshipped that planet.

SAMYDA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is quinquepartite and coloured; there is no corolla; the capsule in the inside resembles a berry, is trivalved and unilocular; the seeds nestling. There are nine species, chiefly shrubs of the West Indies.

SAND, in natural history, a genus of fossils, the characters of which are, that they are found in minute concretions, forming together a kind of powder, the genuine particles of which all have a tendency to one determinate shape, and appear regular, though more or less complete concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not soluble in, nor effervescing with, acids. Sands are subject to be variously blended both with homogeneous and heterogeneous substances, as that of talcs, &c. and hence, as well as from their various colours, are subdivided into, 1. White sands, whether pure or mixed with other arenaceous or heterogeneous particles; of all which there are several species, differing no less in the fineness of their particles than in the different degrees of colour, from a bright and shining white to a brownish, yellowish, greenish, &c. white. 2. The red and reddish sands, both pure and impure. 3. The yellow sands, whether pure or mixed, are also very numerous. 4. The brown sands, distinguished in the same manner. 5. The black sands, of which there are only two species, viz. a fine shining greyish-black sand, and another of a fine shining reddish-black colour. 6. The green kind, of which there is only one known species, viz. a coarse variegated dusky-green sand, common in Virginia.

Sand is of great use in the glass manufacture; the white writing-sand being employed for making of the white glass, and a coarse greenish-looking sand for the green glass.

In agriculture it seems to be the office of sand to make unctuous earths fertile, and fit to support vegetables, &c. For earth alone, we find, is liable to coalesce, and gather into a hard coherent mass. Common sand is, therefore, a very good addition, by way of manure, to all sorts of clay-lands; it warms them, and makes them more open and loose. The best sand for the farmer's use is that which is washed by rains from roads or hills, or that which is taken from the beds of rivers; the common sand that is dug in pits never answers so well. However, if mixed with dung, it is much better than laid on alone; and a very fine manure is made by covering the bottom of sheep-folds with several loads of sand every week, which are to be taken away, and laid on cold stiff lands, impregnated as they are with the dung and the urine of the sheep.

The sea-sand, used as manure in different parts of the kingdom, is of three kinds: that about Plymouth, and on other of the southern coasts, is of a blue-grey colour, like ashes, which is probably owing to the shells of muscles, and other fish of that or the like colour, being broken and mixed among it in great quantity. Westward, near the Land's-end, the sea-sand is very white, and about the isles of Scilly it is very glistening, with small particles of talc; on the coasts of the North Sea the sand is yellowish, brown, or reddish, and contains so great a quantity of fragments of cockle-shells, that it seems to be chiefly composed of them. That sea-sand is accounted best which is of a reddish colour: the next in value to this is the blueish; and the white is the worst of all. Sea-sand is best when taken up from under the water, or from sand-banks which are covered by every tide. The small-grained sand is most sudden in its operation, and is therefore best for the tenant who is only to take three or four crops; but the coarse or large-grained sand is much better for the landlord, as the good it does lasts many years. See HUSBANDRY.

SAND-BAGS, in the art of war, are bags filled with earth or sand, holding each about a cubic foot. Their use is to raise parapets in haste, or to repair what is beaten down.

SAND-EEL. See AMMODYTES.

SANDARACH, in natural history, a very beautiful native fossil, though too often confounded with the common factitious red arsenic, and with the red matter formed by melting the common yellow orpiment. It is a pure substance, of a very even and regular structure, is throughout of that colour which our dyers term an orange-scarlet, and is considerably transparent even in the thickest pieces. But though with respect to colour it has the advantage of cinnabar while in the mass, it is vastly inferior to it when both are reduced to powders. It is moderately hard, and remarkably heavy; and when exposed to a moderate heat, melts and flows like oil. If set on fire, it burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines, and is sold to the painters, who find it a very fine and valuable red; but its virtues or qualities in medicine are no more ascertained at this time than those of the yellow orpiment.

SANDARACH, *gum*. See RESIN.

SANDARACHA. The resinous substance called sandarach is not a pure resin; for when dissolved in alcohol an insoluble residuum remains. Giese, an apothecary of Augsburg, examined this residuum in 1802, and found that it possessed peculiar properties. We have therefore distinguished it by the name of sandaracha. It amounts to about one-fifth of the sandarach. When purified by repeated digestions in alcohol, it possesses the following properties:

1. Its colour is greyish white. It is brittle, and easily pounded.

2. It burns with a bright flame and much smoke, leaving a black residue like colophonium, partly soluble in hot alcohol.

3. It is insoluble in water and in alcohol; but ether dissolves it. The solution, when evaporated, leaves on bodies a stain like lime. When alcohol is added to the solution, the sandaracha is precipitated; but water does not produce this effect.

4. It is soluble in sulphuric acid. But,

5. Nitric acid has no action on it cold.

SANDIVER, a whitish salt, continually cast up from the metal, as it is called, whereof glass is made, and swimming on its surface, is skimmed off. See GLASS.

SANDORICUM, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is quinquedentate; the petals five, and linear-shaped; the nectarium has ten dentæ, on which the antheræ grow; the fruit is a drupe, and five in number, each of which has one seed.

There is only one species, viz. the indicum, a tree of Africa and the East Indies.

SANGUIFICATION. See PHYSIOLOGY.

SANGUINARIA, *blood-wort*, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 27th order, rhœadeæ. The corolla is octopetalous; the calyx diphyllous; the siliqua ovate and unilocular. There is only one species, viz. the canadensis, a native of the northern parts of America, where it grows plentifully in the woods; and in the spring, before the leaves of the trees come out, the surface of the ground is in many places covered with the flowers, which have some resemblance to our wood anemone; but they have short naked pedicles, each supporting one flower at top. Some of these flowers will have ten or twelve petals, so that they appear to have a double range of leaves, which has occasioned their being termed double flowers; but this is only accidental, the same roots in different years producing different flowers. The plant can bear the open air in this country, but should be placed in a loose soil and sheltered situation, not too much exposed to the sun. It is propagated by the roots, which may be taken up and parted in September every other year. The Indians paint themselves yellow with the juice of these plants.

SANGUISORBA, *greater wild burnet*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The calyx is diphyllous; the germen situated betwixt the calyx and corolla. The most remarkable species, of three, is the officinalis, with oval spikes. This grows naturally in moist meadows in many parts of Britain. The cultivation of this plant has been greatly recommended as food to cattle. See HUSBANDRY.

SANHEDRIM, or SANHEDRIN, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim. The room they met in was a rotunda, half of which was built without the temple, and half within. The nasi, or president of the sanhedrim, sat upon a throne, with his deputy on his right hand, his sub-deputy on his left, and the other senators ranged in order on each side. The authority of this council was very extensive, for they decided such causes as were brought before them by way of appeal from the inferior courts; and the king, the high priests, and prophets, were under the jurisdiction of this tribunal. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

There were several inferior sanhedrims in Palestine, each of which consisted of twenty-three persons; all these depended on the great sanhedrim of Jerusalem.

SANICULA, *sanicle* or *self-heal*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The umbels are close together, almost in a round head; the fruit is scabrous; the flowers of the disk abortive. There are three species. The europæa is found in many parts both of Scotland and England. This plant was long celebrated for its healing virtues both internally and externally; but it is now totally disregarded.

SANIDIUM, in natural history, the name of a genus of fossils of the class of the selenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way distinguishable by its external figure, being made up of several plain flat plates.

SANTALUM, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is superior; the corolla monopetalous; the stamina placed in the tube; the stigma is simple; the fruit a berry.

The santalum, sanders or sandel wood, grows to the size of a walnut-tree. Its leaves are entire, oval, and placed opposite to each other. Its wood is white in the circumference, and yellow in the centre, when the tree is old. This difference of colour constitutes two kinds of sanders, both employed for the same purposes, and having equally a bitter taste, and an aromatic smell. With the powder of this wood a paste is prepared, with which the Chinese, Indians, Persians, Arabians, and Turks, anoint their bodies. It is likewise burnt in their houses, and yields a fragrant and wholesome smell. The greatest quantity of this wood, to which a sharp and attenuating virtue is ascribed, remains in India. The red sanders, though in less estimation, and less generally used, is sent by preference into Europe. This is the produce of a different tree, which is common on the coast of Coromandel. Some travellers confound it with the wood of Caliatour, which is used in dyeing.

The santalum album, or white sanders, is brought from the East Indies in billets about the thickness of a man's leg, of a pale-whitish colour. It is that part of the yellow sanders wood which lies next the bark. Great part of it, as met with in the shops, has no smell or taste, nor any sensible quality that can recommend it to the notice of the physician.

The santalum flavum, or yellow sanders, is the interior part of the wood of the same tree which furnishes the former, is of a pale yellowish colour, of a pleasant smell, and a bitterish aromatic taste, accompanied with an agreeable kind of pungency. This elegant wood might undoubtedly be applied to valuable medical purposes, though at present very rarely used. Distilled with water, it yields a fragrant essential oil, which thickens in the cold into the consistence of a balsam. Digested in pure spirit, it imparts a rich yellow tincture; which being committed to distillation, the spirit arises without bringing over any thing considerable of the flavour of the sanders. The residuum contains the virtues of six times its weight of the wood. Hoffman looks upon this extract as a medicine of similar virtues to ambergris; and recommends it as an excellent restorative in great debilities.

SANTOLINA, *lavender-cotton*, a genus of the order of polygamia æqualis, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; there is no pappus; the calyx imbricated and hemispherical. There are six species. The most remarkable are,

1. Chamæcyparisus, or common lavender-cotton, which has been long known in the English gardens. It was formerly titled abrotanum fœminea, or female southernwood, and by the corruption of words was called brotany by the market-people. It grows naturally in Spain, Italy, and the warm parts of Europe. 2. The rosmarinifolia. 3. The anthemoides.

All these plants may be cultivated so as to become ornaments to a garden, particularly in small bosquets of evergreen shrubs, where, if they are artfully intermixed with other plants of the same growth, and placed in the front line, they will make an agreeable variety. They may be propagated by planting slips or cuttings during the spring.

SANIES, in medicine, a serous putrid matter, issuing from wounds; it differs from pus, which is thicker and white.

SAP. See PLANTS, *physiology of*.

SAP, or SAPP, in the art of war, is the digging deep under the earth of the glacis, in order to open a covered passage into the moat. It is only a deep trench, covered at top with boards, hurdles, earth, sand-bags, &c. and is usually begun five or six fathoms from the saliant angle of the glacis. See FORTIFICATION.

SAP-COLOURS, a name given to various expressed juices of a viscid nature, which are inspissated by slow evaporation for the use of painters; as sap-green, gamboge, &c.

SAPINDUS, the *soap-berry tree*, a genus of the trigynia order, in the octandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is tetraphyllous; the petals four; the capsules are fleshy, connate, and ventricose.

The species are 13, of which the most noted are, the saponaria, spinosus, trifoliatus, and chinensis. The saponaria, with winged leaves, grows naturally in the islands of the West Indies, where it rises with a woody stalk from 20 to 30 feet high, sending out many branches with winged leaves composed of several pair of spear-shaped lobes. The flowers are produced in loose spikes at the end of the branches; they are small and white, so make no great appearance. These are succeeded by oval berries as large as middling cherries, sometimes single, at others, two, three, or four are joined together; these have a saponaceous skin or cover, which incloses a very smooth roundish nut of the same form, of a shining black when ripe. The skin or pulp which surrounds the nuts is used in America to wash linen; but it is very apt to burn and destroy it if often used, being of a very acrid nature.

These plants are propagated by seeds, and kept in the stove.

SAPONARIA, *sopewort*, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophylleæ. The calyx is monophyllous and naked; there are five ungulated petals; the capsule is oblong and unilocular.

There are nine species, the officinalis, vaccaria, cretica, porrigens, illyrica, ocymoides, orientalis, lutea, and bellidifolia. The officinalis, which is a British plant, has a creeping root, so that in a short time it would fill a large space of ground. The stalks are above two feet high, and of a purplish colour. The footstalks of the flowers arise from the wings of the leaves opposite; they sustain four, five, or more purple flowers each, which have generally two small leaves placed under them. The stalk is also terminated by a loose bunch of flowers growing in form of an umbel; they have each a large swelling cylindrical empalement, and five broad obtuse petals, which spread open, of a purple colour. These are succeeded by oval capsules, with one cell filled with small seeds. The decoction of this plant is used to cleanse and scour woollen cloths: the poor people in some countries use it instead of soap for washing; from which use it had its name.

SAPPHIRE, a genus of precious stones, of a blue colour, and the hardest of all except the ruby and diamond. They are found in the same countries with the ruby; also in Bohemia, Alsace, Siberia, and Auvergne. M. Romé de l'Isle mentions one found at Auvergne, which appeared quite green or blue according to the position in which it was viewed. Cronstedt, however, informs us, that the blue fluor spars are frequently met with in collections under the name of sapphires; and it is certain from Pliny, b. 37. chap. 9. that the sapphire of the antients was our lapis lazuli. They are seldom found of a deep-blue colour throughout, or free from parallel veins; and when they are but slightly tinged, they are named white sapphires. The late unfortunate king of France had one with a stripe of fine yellow topaz in the middle. Some are found half green and half red, and are foliated like the ruby. The fine hard sapphires, called by the jewellers oriental, are of the same nature with the ruby and topaz, excepting the mere circumstance of colour. They are commonly in two oblong hexagon pyramids, joined at their base, and pointed at top; sometimes also in hexagonal columns.

The specific gravity of these precious stones, according to Bergman, is from 3.650 to 3.940. According to others, the specific gravity of the oriental sapphires is 3.994; that of the Brasilian 3.1307; and of those from Puy in Auvergne, 4.0769. When powdered, they are fusible with borax or microcosmic salt, into a transparent glass; and the same thing happens on treating them with magnesia alba. They are said to lose their colour by fire, and to become so hard and transparent as sometimes to pass for diamonds; but Mr. Achard found this to be a mistake, and that the true sapphires are not in the least altered either in colour, hardness, or weight, by the most intense fire. Those of Puy in Auvergne, however, though by their colour and hardness they seem to approach the oriental sapphires, lose both their colour and transparency in the fire, becoming black, and even vitrifying; which plainly shows them to be of a different kind. See CORUNDUM.

SARABANDE, a dance said to be originally derived from the Saracens. According to some authors, it had its appellation from a comedian named Sarabandi, who first introduced it in France. The tune of the sarabande is written in $\frac{3}{2}$ or $\frac{3}{4}$, and its character is both expressive and majestic. One of its distinguishing features is the lengthening the second note of the measure, which at once gives a gravity and consequence to the movement.

SARACA, a genus of the hexandria order, in the diadelphia class of plants. There is no calyx; the corolla is funnel-shaped and quadrifid; the filaments are on each side the throat of the corolla; the legumen is pedicellated. There is one species, a tree of the East Indies.

SARCASM, in rhetoric, a keen bitter expression, which has the true point of satire, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour, "He saved others, himself he cannot save."

SARCOCELE. See SURGERY.

SARCOCOLL, a vegetable substance that possesses the following properties:

1. Solid, semi-transparent bodies; usually having a tinge of yellow: taste sweet, but leaving an impression of bitterness. Dissolves in the mouth like gum.

2. Equally soluble in water and alcohol; solution yellow. The watery solution has the appearance of mucilage, and may be used for the same purposes.

3. Cannot be made to crystallize.

4. When heated, softens, but does not melt. It emits a slight smell of calomel. When strongly heated, it blackens, and assumes the consistence of tar, emitting a white heavy smoke having an acrid odour. In a strong fire it scarcely leaves any residuum.

These properties shew us that sarcocoll is a substance intermediate between sugar and gum, partaking in some measure of the properties of each, but certainly approaching nearer to sugar than to gum. How far the combination of sugar and the bitter principle would resemble sarcocoll, has not been tried. The three following species may be referred to sarcocoll.

1. *Common sarcocoll.* This substance is usually sold in the state of oblong globules from the size of a pea to that of a particle of sand. Its colour is usually yellow; and it has the semitransparency and much of the appearance of gum arabic. But some of the grains are reddish-brown. Its smell is peculiar, and not unlike that of anise-seed. When carefully examined, four different substances may be detected: the first, and by far the most abundant, is pure sarcocoll; the second consists of small woody fibres, and a soft yellowish-white substance, not unlike the covering of the seeds of some of the cruciform plants; the third is a reddish-brown substance apparently earthy; and the fourth is only detected when the sarcocoll is dissolved in water or alcohol. It then appears in soft transparent tremulous masses like jelly.

The pure sarcocoll amounts to 0.8 of the whole. When the sarcocoll is dissolved in alcohol or water, and obtained again by evaporation, it loses its smell. It then assumes the form of semitransparent brittle brown cakes very like gum.

Sarcocoll exudes spontaneously from the penæa sarcocolla; a shrub which is said by botanical writers to be indigenous in the north-eastern parts of Africa. Nothing precise is known concerning the way in which it exudes.

SARDONYX, a precious stone consisting of a mixture of the chalcedony and carnelian, sometimes in strata, but at other times blended together. It is found, 1. Striped with white and red strata, which may be cut in cameo as well as the onyx. 2. White with red dendritical figures, greatly resembling the mocha-stone; but with this difference, that the figures in the sardonyx are of a red colour, in the other black. There is no real difference, excepting in the circumstance of hardness, between the onyx, carnelian, chalcedony, sardonyx, and agate, notwithstanding the different names bestowed upon them. Mongez informs us, that the yellow, or orange-coloured agates, with a wavy or undulating surface, are now commonly called sardonyx.

SARMENTOSÆ (from *sarmentum*, a long shoot like that of a vine), the name of the 11th class in Linnæus's Fragments of a Natural Method, consisting of plants which have climbing stems and branches, that, like the vine, attach themselves to the bodies in their neighbourhood for the purpose of support. See BOTANY.

SAROTHRA, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. The corolla is pentapetalous; the capsule unilocular, trivalved, and coloured. There is one species, an annual of Virginia.

SARPLAR *of wool*, a quantity of wool, otherwise called a pocket or half-sack; a sack containing 80 tod; a tod two stone; and a stone 14 pounds. In Scotland it is called sarpliath, and contains 80 stone.

SARRACENIA, *side-saddle plant*, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The corolla is pentapetalous; the calyx is double, and triphyllous below, pentaphyllous above; the capsule quinquelocular; the style has a stigma of the form of a shield. There are five species, herbs of North America.

SARSAPARILLA. See SMILAX.

SARTORIUS. See ANATOMY.

SASH, a mark of distinction, which in the British service is generally made of crimson silk for the officers, and of crimson mixed with white cotton for the serjeants. It is worn round the waist in most regiments; in some few, particularly in the Highland corps, it is thrown across the shoulder. Sashes were originally invented for the convenience and ease of wounded officers, &c. by means of which, in case any of them were so badly wounded as to render them incapable of remaining at their posts, they might be carried off with the assistance of two men. They are now reduced to a very small size, and of course unfit for the original purpose. Both the sash and gorget, indeed, must be considered as mere marks of distinction, to point out officers on duty. In some instances they are worn together; in others, the gorget is laid aside, and the sash only worn. The British cavalry tie the sash on the right, the infantry on the left, side. The sashes for the imperial army are made of crimson and gold, for the Prussian army black silk and silver, the Hanoverians yellow silk, the Portuguese crimson silk with blue tassels. The modern French have their sashes made of three colours, viz. white, pink, and light-blue, to correspond with the national flag.

SASSAFRAS, the wood of an American tree. See LAURUS. It is said to be warm, aperient, and corroborant; and frequently employed as an infusion, in the way of tea, is a very pleasant drink: its oil is very fragrant, and possesses most of the virtues of the wood.

SATELLITE. See ASTRONOMY.

SATRAPA, or SATRAPES, in Persian antiquity, denotes an admiral, but more commonly the governor of a province.

SATURATION, like most other technical terms introduced into chemistry before the science had acquired much precision, has been used with a great deal of latitude, being sometimes taken in one sense and sometimes in another. But in order to be understood, it is necessary to use the word with some degree of precision.

If we make the attempt, we shall find that water will not dissolve any quantity of salt that we please. At the temperature of 60°, it dissolves only 0.354 parts of its weight of salt; and if more salt than this is added, it remains in the water undissolved. When water has dissolved as much salt as possible, it is said to be saturated with salt. This sense is at least analogous to the original meaning of the word. Whenever, then, a substance A refuses to combine with an additional quantity of another body B, we may say that it is saturated with B. It takes place whenever the affinity of the water and salt, is balanced by the cohesion of the particles of the salt, and therefore indicates that these two forces are equal.

In the same manner, water, after having absorbed a certain quantity of carbonic acid gas, refuses to absorb any more. We may indeed pass carbonic acid gass through water in this state, but it makes its escape unaltered. Water which refuses to absorb carbonic acid gas is saturated with that acid. This saturation takes place when the affinity between the gas and the water is balanced by the elasticity of the gas, and indicates of course that these two forces are equal.

In these two instances the saturation is occasioned by opposite causes. The salt refuses to dissolve in the water when the cohesion of its particles equals its affinity for the water; the carbonic acid gas, when the repulsion of its particles equals its affinity for water. In the first case, it is the attractive force of cohesion which opposes farther solution; in the second case, it is the repulsive force of elasticity. Hence the different method which must be followed to diminish these forces, and enable the water to dissolve a greater proportion of these respective bodies. Heat, by diminishing the force of cohesion, enables water to dissolve a greater proportion of saline bodies. Accordingly we find that in most cases hot water dissolves more salt than cold water. Common salt is almost the only exception to this general law. On the other hand, cold, by diminishing the elasticity, or at least the expansibility of gaseous bodies, enables water to dissolve a greater proportion of them. Thus the colder the water is, the greater a proportion of carbonic acid is it capable of dissolving. The freezing point of water limits this increase of solubility, because at that point the cohesive force of the particles of water becomes so great as to cause them to cohere, to the exclusion of those bodies with which they were formerly combined. Hence the reason, that most bodies separate from water when it freezes. But they generally retard the freezing considerably, by opposing with all the strength of their affinity the cohesion of the water. The consequence is, that the freezing point of water, when it holds bodies in solution, is lower than the freezing point of pure water. A table of the freezing points of different saline solutions would be a pretty accurate indication of the affinity of the different salts for water: for the affinity of each salt is of course proportional to the degree of cold at which it separates from the water, that is, to the freezing point of the solution.

In this sense of the word saturation, which is certainly the only one that it ought to bear, it may be said with propriety that there are certain bodies which cannot be saturated by others. Thus water is capable of combining with any quantity whatever of sulphuric acid, nitric acid, and alcohol; and all bodies seem capable of combining with almost any quantity whatever of caloric. Several of the metals, too, are capable of combining with any quantity whatever of some other metals. In general, it may be said that those bodies called solvents are capable of combining in any quantity with the substances which they hold in solution. Thus water may be added in any quantity, however great, to the acids, and to the greater number of salts.

If we take a given quantity of sulphuric acid diluted with water, and add to it slowly the solution of soda by little at a time, and examine the mixture after every addition, we shall find that for a considerable time it will exhibit the properties of an acid, reddening vegetable blues, and having a taste perceptibly sour; but these acid properties gradually diminish after every addition of the alkaline solution, and at last disappear altogether. If we still continue to add the soda, the mixture gradually acquires alkaline properties, converting vegetable blues to green, and manifesting an urinous taste. These properties become stronger and stronger the greater the quantity of the soda is which is added. Thus it appears that when sulphuric acid and soda are mixed together, the properties either of the one or the other preponderate according to the proportions of each; but that there are certain proportions, according to which when they are combined, they mutually destroy or disguise the properties of each other, so that neither predominates, or rather, so that both disappear.

When substances thus mutually disguise each other's properties, they are said to neutralize one another. This property is common to a great number of bodies; but it manifests itself most strongly, and was first observed, in the acids, alkalies, and earths. Hence the salts which are combinations of these different bodies received long ago the name of neutral salts. When bodies are combined in the proportion which produces neutralization, they are often said to be saturated; but in this case the term is used improperly. It would be much better to confine the word saturation to the meaning assigned to it in the beginning of this article, and to employ the term neutralization to denote the state in which the peculiar properties of the component parts mutually disappear; for very frequently neutralization and saturation by no means coincide. Thus in tartrite of potass the acid and alkali neutralize each other; yet it cannot be said that the potass is saturated; for it is still capable of combining with more tartarous acid, and of forming supertartrite of potass, a compound in which the ingredients do not neutralize each other; for the salt has manifestly a preponderance of the properties of the acid.

SATUREIA, *savoury*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The segments of the corolla are nearly equal; the stamina standing asunder. There are eight species; the most noted are: 1. The hortensis, or summer savoury, is an annual plant, which grows naturally in the south of France and Italy, but is cultivated in this country both for the kitchen and medicinal use. 2. The montana, or winter savoury, a perennial plant, growing naturally in the south of France and Italy, but is cultivated in gardens both for culinary and medicinal purposes. Both kinds are propagated by seeds. Summer savoury is a very warm pungent aromatic, and affords in distillation with water a subtile essential oil, of a penetrating smell, and very hot acrid taste. It yields little of its virtues by infusion to aqueous liquors; rectified spirit extracts the whole of its taste and smell, and elevates nothing in distillation.

SATURN. See ASTRONOMY.

SATYR, or SATIRE. See POETRY.

SATYRIUM, a genus of the diandria order, in the gynandria class of plants; and in the natural method ranking under the 42d order, verticillatæ. The nectarium is scrotiform, or inflated double behind the flower. There are 21 species.

SAUCISSON, in fortification, a mass of large branches of trees bound together; and differing only from a fascine, as this is composed of small branches of twigs.

SAVIN. See JUNIPERUS.

SAVIOUR, *Order of St.* a religious order in the Romish church, founded by St. Bridget, about the year 1345; and so called from its being pretended that our Saviour himself dictated to the foundress its constitutions and rules.

According to the constitutions, this order is principally founded for religious women who pay a particular honour to the holy virgin; but there are some monks of the order, to administer the sacraments, and spiritual assistance to the nuns. The number of nuns is fixed at sixty in each monastery; and that of the religious priests at thirteen, according to the number of the apostles, of whom St. Paul was the thirteenth. There are also four deacons, representing the four doctors of the church, St. Ambrose, St. Augustin, St. Gregory, and St. Jerome; and eight lay-brothers; who altogether make up the number of the thirteen apostles, and the seventy-two disciples of Jesus Christ. The nuns are not admitted till eighteen years of age, nor the friars before twenty-five; and they are to perform a year's novitiate.

SAUNDERS. See SANTALUM.

SAURURUS, a genus of the tetragynia order, in the heptandria class of plants; and in the natural method ranking under the second order, piperitæ. The calyx is a catkin, with uniflorous scales: there is no corolla;

there are four germina, and four monospermous berries. There is one species, a herb of Virginia.

SAUVAGESIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous and fringed; the calyx pentaphyllous; the nectarium the same, having its leaves placed alternately with the petals; the capsule unilocular. There is one species, a native of St. Domingo.

SAW, an instrument which serves to cut into pieces several solid matters; as wood, stone, ivory, &c. The best saws are of tempered steel ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their being stiffer, are likewise found smoother than the last. They are known to be well hammered by the stiff bending of the blade; and to be well and evenly ground, by their bending equally in a bow. The edge in which are the teeth is always thicker than the back, because the back is to follow the edge. The teeth are cut and sharpened with a triangular file, the blade of the saw being first fixed in a whetting-block. After they have been filed the teeth are set, that is, turned out of the right line, that they may make the kerf or fissure the wider, that the back may follow the better. The teeth are always set ranker for coarse cheap stuff than for hard and fine, because the ranker the teeth are set, the more stuff is lost in the kerf. The saws by which marble and other stones are cut, have no teeth: these are generally very large, and are stretched out and held even by a frame.

The lapidaries, too, have their saw, as well as the workmen in mosaic; but of all mechanics, none have so many saws as the joiners; the chief are as follows: The pit-saw, which is a large two-handed saw, used to saw timber in pits; this is chiefly used by the sawyers. The whip-saw, which is also two-handed, used in sawing such large pieces of stuff as the hand-saw will not easily reach. The hand-saw, which is made for a single man's use, of which there are various kinds; as the bow, or frame saw, which is furnished with cheeks: by the twisted cords which pass from the upper parts of these cheeks, and the tongue in the middle of them, the upper ends are drawn closer together, and the lower set further apart. The tenon-saw, which being very thin, has a back to keep it from bending. The compass-saw, which is very small, and its teeth usually not set: its use is to cut a round, or any other compass-kerf: hence the edge is made broad, and the back thin, that it may have a compass to turn in.

SAW-MILLS. In early periods, the trunks of trees were split with wedges into as many and as thin pieces as possible; and if it was necessary to have them still thinner, they were hewn on both sides to the proper size. This simple and wasteful manner of making boards has been still continued in some places, to the present time. Peter the Great of Russia endeavoured to put a stop to it, by forbidding hewn deals to be transported on the river Neva. The saw, however, though so convenient and beneficial, has not been able to banish entirely the practice of splitting timber used in building, or in making furniture and utensils, for we do not speak here of fire-wood; and, indeed, it must be allowed that this method is attended with peculiar advantages, which that of sawing can never possess. The wood-splitters perform their work more expeditiously than sawyers, and split timber is much stronger than that which has been sawn; for the fissure follows the grain of the wood, and leaves it whole; whereas the saw, which proceeds in the line chalked out for it, divides the fibres, and by these means lessens its cohesion and solidity. Split timber, indeed, turns out often crooked and warped; but in many purposes to which it is applied this is not prejudicial; and these faults may sometimes be amended. As the fibres, however, retain their natural length and direction, thin boards, particularly, can be bent much better. This is a great advantage in making pipe-staves, or sieve-frames, which require still more art, and in forming various implements of the like kind.

Our common saw, which needs only to be guided by the hand of the workman, however simple it may be, was not known to the inhabitants of America when they were subdued by the Europeans. The inventor of this instrument has by the Greeks been inserted in their mythology, with a place in which, among their gods, they honoured the greatest benefactors of the earliest ages. By some he is called Talus, and by others Perdix. Pliny alone ascribes the invention to Dædalus; but Hardouin, in the passage where he does so, chooses to read Talus rather than Dædalus. Diodorus Siculus, Apollodorus, and others, name the inventor Talus. He was the son of Dædalus's sister; and was by his mother placed under the tuition of her brother, to be instructed in his art. Having once found the jaw-bone of a snake, he employed it to cut through a small piece of wood; and by these means was induced to form a like instrument of iron, that is, to make a saw. This invention, which greatly facilitates labour, excited the envy of his master, and instigated him to put Talus to death privately. We are told, that being asked by some one, when he was burying the body, what he was depositing in the earth, he replied, "A serpent." This suspicious answer discovered the murder; and thus, adds the historian, a snake was the cause of the invention, of the murder, and of its being found out.

Others call the inventor Perdix. That he was the son of a sister of Dædalus they all agree; but they differ respecting the name of his parents. The mother is by Fulgentius called Polycastes, but without any proof; and Lactantius gives to the father the name of Calaus. In Apollodorus, however, the mother of Talus is called Perdix; and the same name is given by Tzetzes to the mother of the inventor, whose name Talus he changes into Attalus. Perdix, we are told, did not employ for a saw the jaw-bone of a snake, like Talus, but the back-bone of a fish; and this is confirmed by Ovid, who, nevertheless, is silent respecting the name of the inventor.

The saws of the Grecian carpenters had the same form, and were made in the like ingenious manner as ours are at present. This is fully shewn by a painting still preserved among the antiquities of Herculaneum. Two genii are represented at the end of a bench, which consists of a long table that rests upon two four-footed stools. The piece of wood which is to be sawn through is secured by cramps. The saw with which the genii are at work has a perfect resemblance to our frame-saw. It consists of a square frame, having in the middle a blade, the teeth of which stand perpendicular to the plane of the frame. The piece of wood which is to be sawn extends beyond the end of the bench, and one of the workmen appears standing, and the other sitting on the ground. The arms, in which the blade is fastened, have the same form as that given to them at present. In the bench are seen holes, in which the cramps that hold the timber are struck. They are shaped like the figure 7; and the ends of them reach below the boards that form the top of it.

The most beneficial and ingenious improvement of this instrument was, without doubt, the invention of saw-mills, which are driven either by water or by the wind. Mills of the first kind were erected so early as the fourth century, in Germany, on the small river Roeur or Ruer: for though Ausonius speaks properly of water-mills for cutting stone, and not timber, it cannot be doubted that these were invented later than mills for manufacturing deals, or that both kinds were erected at the same time. The art, however, of cutting marble with a saw is very old. Pliny conjectures that it was invented in Caria; at least he knew no building incrusted with marble of greater antiquity than the palace of king Mausolus, at Halicarnassus. This edifice is celebrated by Vitruvius, for the beauty of its marble; and Pliny gives an account of the different kinds of sand used for cutting it; for it is the sand properly, says he, and not the saw, which produces that effect. The latter presses down the former, and rubs it against the marble; and the coarser the sand is, the longer will be the time required to polish the marble which has been cut by it. Stones of the soap-rock kind, which are indeed softer than marble, and which would require less force than wood, were sawn at that period: but it appears that the far harder glassy kinds of stone were sawn then also; for we are told of the discovery of a building which was encrusted with cut agate, carnelian, lapis lazuli, and amethysts. We have, however, found no account in any of the Greek or Roman writers of a mill for sawing wood; and as the writers of modern times speak of saw-mills as new and uncommon, it would seem that the oldest construction of them has been forgotten, or that some important improvement has made them appear entirely new.

Becher says, with his usual confidence, that saw-mills were invented in the 17th century. In this he erred, for when the infant Henry sent settlers to the island of Madeira, which was discovered in 1420, and caused European fruits of every kind to be carried thither, he ordered saw-mills to be erected also, for the purpose of sawing into deals the various species of excellent timber with which the island abounded, and which were afterwards transported to Portugal. About the year 1427 the city of Breslau had a saw-mill, which produced a yearly rent of three marks; and in 1490 the magistrates of Erfurt purchased a forest, in which they caused a saw-mill to be erected, and they rented another mill in the neighbourhood besides.

Norway, which is covered with forests, had the first saw-mill about the year 1530. This mode of manufacturing timber was called the new art; and because the exportation of deals was by these means increased, that circumstance gave occasion to the deal-tythe, introduced by Christian III. in the year 1545. Soon after the celebrated Henry Canzau caused the first mill of this kind to be built in Holstein. In 1552 there was a saw-mill at Joachimsthal, which, as we are told, belonged to Jacob Geusen, mathematician. In the year 1555 the bishop of Ely, ambassador from Mary queen of England to the court of Rome, having seen a saw-mill in the neighbourhood of Lyons, the writer of his travels thought it worthy of a particular description. In the sixteenth century, however, there were mills with different saw-blades, by which a plank could be cut into several deals at the same time. The first saw-mill was erected in Holland at Saardam, in the year 1596; and the invention of it is ascribed to Cornelius Cornelissen. Perhaps he was the first person who built a saw-mill at that place, which is a village of great trade, and has still a great many saw-mills, though the number of them is becoming daily less; for within the last thirty years a hundred have been given up. The first mill of this kind in Sweden was erected in the year 1653. At present, that kingdom possesses the largest perhaps ever constructed in Europe, where a water-wheel, twelve feet broad, drives at the same time seventy-two saws.

In England saw-mills had at first the same fate that printing had in Turkey, the ribbon-loom in the dominions of the church, and the crane at Strasburgh. When attempts were made to introduce them, they were violently opposed, because it was apprehended that the sawyers would be deprived by them of their means of getting a subsistence. For this reason, it was found necessary to abandon a saw-mill erected by a Dutchman near London, in 1663; and in the year 1700, when one Houghton laid before the nation the advantages of such a mill, he expressed his apprehension that it might excite the rage of the populace. What he dreaded was actually the case in 1767 or 1768, when an opulent timber-merchant, by the desire and approbation of the Society of Arts, caused a saw-mill, driven by wind, to be erected at Limehouse, under the direction of James Stansfield, who had learned, in Holland and Norway, the art of constructing and managing machines of that kind. A mob assembled, and pulled the mill to pieces; but the damage was made good by the nation, and some of the rioters were punished. A new mill was afterwards erected, which was suffered to work without molestation, and which gave occasion to the erection of others. It appears, however, that this was not the only mill of the kind then in Britain; for one driven also by wind had been built at Leith, in Scotland, some years before.

The mechanism of a sawing-mill may be reduced to three principal things: the first, that the saw is drawn up and down as long as is necessary, by a motion communicated by water to the wheel: the second, that the piece of timber to be cut into boards is advanced by an uniform motion to receive the strokes of the saw; for here the wood is to meet the saw, and not the saw to follow the wood, therefore the motion of the wood and that of the saw ought immediately to depend the one on the other: the third, that when the saw has cut through the whole length of the piece, the whole machine stops of itself, and remains immoveable; for fear, lest having no obstacle to surmount, the force of the water should turn the wheel with too great rapidity, and break some part of the machine.

The upper part of Plate Saw-mill, &c. represents the circular saw-mill introduced by Mr. George Smart, and used by him in his manufactory at Ordnance-wharf, Westminster-bridge. ABD, fig. 1, is a strong bench, similar to those used by carpenters. In the middle of this, is an opening through which the saw E comes. The saw L, figs. 1 and 2, is a circular plate of steel, with teeth like those of a large pit-saw on its circumference, and a round hole in the middle of it, through which the spindle E, fig. 2, of the saw passes. It is prevented from slipping round it, by a flanch *e* fixed to the spindle E, and another, *f*, which slips on the spindle, and is pressed against the saw by a nut *b*, screwed on the end of the spindle, so as to hold the saw tight between the flanches, and by unscrewing the nut, the saw can be taken off to be sharpened, and another put in its place in a very short time. The ends of the spindle are brought to points, which work in small holes in the ends of screws, one of which is seen at *d*, fig. 1: the other screw is put through a piece of wood F, supported by the two uprights GG, and can be raised or lowered at pleasure by wedges, so as to bring the plane of the saw exactly at right angles. To the surface of the bench the saw is turned round with a great velocity by a strap passing round the rigger H and the wheel I, which receives its motion from a horse-wheel

The piece of wood to be sawn is guided by a straight bar K, which is always made to move parallel to the plane of the saw by two iron coupling-rods *hh*, so that it can be set at any distance from the saw, according to the width of the piece to be cut, and held there by screws.

The machine before us is chiefly used for ripping up three-inch deal planks. The bar K is set the proper distance from the saw, and screwed fast. The workman takes the plank, and laying its edge against the bar K, shoves it endways against the saw, which, as it turns, cuts the wood with surprising quickness.

SAXIFRAGA, *saxifrage*, a genus of the digynia order, in the decandria class of plants; and in the natural method ranking under the 13th order, succulentæ. The calyx is quinquepartite; the corolla pentapetalous; the capsule birostrated, unilocular, and polyspermous.

There are 50 species, of which the most remarkable are, 1. The granulata, or white saxifrage, which grows naturally in the meadows in many parts of England. The roots of this plant are like grains of corn, of a reddish colour without: there is a variety of this with double flowers, which is very ornamental. The leaves are tongue-shaped, gathered into heads, rounded at their points, and have cartilaginous and sawed borders. The stalk rises two feet and a half high, branching out near the ground, forming a natural pyramid to the top. The flowers have five white wedge-shaped petals, and ten stamina, placed circularly the length of the tube, terminated by roundish purple summits. When these plants are strong, they produce very large pyramids of flowers. 2. The umbrosa, commonly called London pride, or none-so-pretty, grows naturally on the Alps, and also in great plenty on a mountain of Ireland, called Mangerton, in the county of Kerry, in that island. The roots of this are perennial. 3. The oppositifolia grows naturally on the Alps, Pyrenees, and Helvetian mountains: it is also found pretty plentifully growing upon Ingleborough hill, in Yorkshire; Snowdon, in Wales; and some other places. It is a perennial plant, with stalks trailing upon the ground. The flowers are produced at the end of the branches, of a deep blue.

SAY, or SAYE, in commerce, a kind of serge, or woollen stuff, much used abroad for linings, and by the religious for shirts: with us it is used for aprons by several sorts of artificers, being usually dyed green.

SCABBARD, *to*, to punish with the scabbard of a bayonet. Infantry soldiers are sometimes scabbarded, under the sanction of the captains of companies, for slight offences committed among themselves. A court-martial is held in the serjeant's room or tent, to ascertain the culprit's guilt; it having been previously left to him to abide by the judgment of his comrades, in this manner, or to be tried by a regimental court-martial.

The word scabbard has been sometimes used in a figurative sense, to distinguish those persons who have obtained rank and promotion in the army without seeing much hard service, from those who have fought their way through all the obstacles of superior interest, &c. Hence the favourite expression of the late sir William Erskine: "Some rise by the scabbard, and some by the sword;" which means more than we are at liberty to illustrate, but which may be easily applied to cases in point.

SCABIOSA, *scabious*, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 48th order aggregatæ. The common calyx is polyphyllous; the proper one is double, superior; the receptacle is paleaceous or naked. There are 42 species. The most remarkable are, 1. The arvensis, or meadow-scabious, grows naturally in many places of Britain. The flowers are produced upon naked footstalks at the ends of the branches; they are of a purple colour, and have a faint odour. 2. The succisa, or devil's bit, grows naturally in woods and moist places. This has a short tap-root, the end of which appears as if it was bitten or cut off, whence the plant has taken its name. Both these have been recommended as aperient, sudorific, and expectorant; but the present practice has no dependance on them.

SCÆVOLA, a genus of the monogynia order, in the pentandria class of plants. The corolla is monopetalous; the tube slit longitudinally; the border quinquefid and lateral. The fruit is a prism inferior and monospermous; the nucleus bilocular. There are three species.

SCALA. See ANATOMY, *Ear*.

SCALDS, in the history of literature, a

name given by the antient inhabitants of the northern countries to their poets, in whose writings their history is recorded.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal scale, plotting scale, Gunter's scale, &c. See INSTRUMENTS, MATHEMATICAL.

SCALE, in music (from the Latin, scala), the denomination first given to the arrangement made by Guido, of the six syllables ut, re, mi, fa, sol, la: also called gamut. This order of sounds, to which the French have added that of si, bears the name of scale, *i. e.* ladder, because it represents a kind of ladder, by means of which the voice or instrument rises to acute, and descends to grave; each of the seven syllables being, in a manner, one step of the ladder.

The word scale is also used to signify a series of sounds rising or falling from any given pitch or tone, to the greatest practicable distance, through such intermediate degrees as make the succession most agreeable and perfect, and in which we have all the harmonical divisions most commodiously divided. This scale is properly called the universal system, as including all the particular systems.

This enumeration of all the diatonic sounds of our system, ranged in order, and which we call scale, was denominated by the Greeks tetrachord, because, in effect, their scale was composed of only four sounds, which they repeated from tetrachord to tetrachord, as we repeat ours from octave to octave.

SCALENE TRIANGLE. See GEOMETRY.

SCALENUS, in anatomy. See NECK.

SCALES *of fish*. See HORN, Vol. I. p. 924, 3d col.

SCAMMONY, in the materia medica. See CONVOLVULUS, and GUM RESINS.

SCANDALUM MAGNATUM, is the special name of a statute, and also of a wrong done to any high personage of the land, as prelates, dukes, marquises, earls, barons, and other nobles; and also the chancellor, treasurer, clerk of the privy seal, steward of the house, justice of one bench or other, and other great officers of the realm, by false news, or horrible or false messages, whereby debates and discord, betwixt them and the commons, or any scandal to their persons, might arise. 2 R. II. c. 5. This statute has given name to a writ, granted to recover damages thereupon. Cowel.—It is now clearly agreed, that though there are no express words in the statute which give an action, yet the party injured may maintain one on this principle of law; that when a statute prohibits the doing of a thing, which, if done, might be prejudicial to another, in such case he may have an action on that very statute for his damage. 2 Mod. 152.

SCANDIX, *cherril, shepherd's needle,* or *Venus's comb*, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The corolla is radiating; the fruit subulated; the petals emarginated; the florets of the disc frequently male. There are eleven species. The most remarkable is the odorata, with angular furrowed seeds. It is a native of Germany; and has a very thick perennial root, composed of many fibres, of a sweet aromatic taste, like aniseed, from which come forth many large leaves that branch out somewhat like those of fern, whence it is named sweet fern.

SCAPEMENT, a general term for the manner of communicating the impulse of the wheels to the pendulum of a clock. Common scapements consist of the swing wheel and pallets only. See CLOCK-WORK.

SCAPOLITE, a mineral found at Arendal, in Norway. It is of a pearl colour, and is crystallized in long, four-sided, rectangular prisms. Faces longitudinally streaked. Its specific gravity is 3.68, and it is hard enough to scratch glass. Fracture foliated in two directions. Before the blowpipe, it froths and melts into white enamel. It is composed of

48	silica
30	alumina
14	lime
1	oxide of iron
2	water
—	
95.	

SCAPULA. See ANATOMY.

SCAPULAR. See ANATOMY.

SCARABÆUS, *beetle*, a genus of insects of the order coleoptera. The generic character is, antennæ or horns clavate, with a fissile tip; legs generally toothed; body thick and compact. This genus is extremely extensive, there being nearly one hundred species. Among these the most remarkable is, 1. The scarabæus Hercules, or Hercules beetle, which sometimes measures not less than five, or even six inches in length: the wing-shells are of a smooth surface, of a blueish or brownish grey colour, sometimes nearly black, and commonly marked with several small, round, deep-black spots, of different sizes: the head and limbs are coal-black: from the upper part of the breast or thorax proceeds a horn or process of enormous length, in proportion to the body: it is sharp at the tip, where it curves slightly downwards, and is marked beneath by two or three denticulations, and furnished throughout its whole length with a fine, short, velvet-like pile, of a brownish orange-colour: from the front of the head proceeds also a strong horn, about two-thirds the length of the former, toothed on its upper face, but not furnished with any of the velvet-like pile which appears on the former. This species is a native of several parts of South America, where great numbers are said to be sometimes seen on the tree called mammæa, rasping off the rind of the slender branches by working nimbly round them with the horns, till they cause the juice to flow, which they drink to intoxication, and thus fall senseless from the tree. This, however, as the learned Fabricius has well observed, seems not very probable; since the thoracic horn, being bearded on its lower surface, would undoubtedly be made bare by this operation. This species, from the large size of all its parts, affords an admirable example of the characters of the genus. It varies much in size, and it may even be doubted whether some of the smaller specimens have not been occasionally regarded by authors as distinct species. The female is destitute both of the frontal and thoracic horn, but in other points resembles the male. See Plate Nat. Hist. fig. 352.

2. Scarabæus Goliathus, the Goliah beetle, is highly remarkable both in point of size and colour: it is larger in body than the preceding, and has a rose-coloured thorax, marked with longitudinal black stripes or variegations, and purple-brown wing-sheaths: the head is divided in front into two forked processes: the limbs are black, and very strong. It is a native of some parts of Africa. A supposed variety sometimes occurs, in which both the thorax and wing-sheaths are of a pale yellowish brown instead of rose-colour, and are marked with black variegations.

3. Scarabæus melolonthas, or cockchafer, is one of the most common European beetles. This insect is extremely familiar in our own island, the larva or caterpillar inhabiting ploughed lands, and feeding on the roots of corn, &c. and the complete insect making its appearance during the middle and the decline of summer. The cockchafer sometimes appears in such prodigious numbers as almost to strip the trees of their foliage, and to produce mischiefs nearly approaching to those of the locust tribe. It appears from a paper by a Mr. Molineux, printed in the Philosophical Transactions for the year 1697, that some particular districts in Ireland were overrun by this insect in a wonderful manner; and the failure of the wheat in the year 1804 has been by some attributed to the numbers of the larva of this insect which were lodged in the earth.

The larva, or caterpillar, of this insect, is said to be two, and sometimes three years, in passing from its first form into that of the perfect insect. The eggs are laid in small detached heaps beneath the surface of some clod, and the young, when first hatched, are scarcely more than the eighth of an inch in length, gradually advancing in their growth, and occasionally shifting their skins, till they arrive at the length of near two inches. At this period they begin to prepare for their change into a chrysalis or pupa, selecting for the purpose some small clod of earth, in which they form an oval cavity, and, after a certain space, divest themselves of their last skin, and immediately appear in the chrysalis form, in which they continue till the succeeding summer, when the beetle emerges from its retirement, and commits its depredations on the leaves of trees, &c. breeds, and deposits its eggs in a favourable situation, after which its life is of very short duration.

4. A much more elegant insect of this kind is the scarabæus fullo, or variegated beetle. It is nearly twice the size of the cockchafer, and of an elegant chesnut-colour, with the wing-sheaths beautifully marbled with white variegations. It is common in many parts of Europe, but extremely rare in England. See Plate Nat. Hist. fig. 351.

5. A species of peculiar beauty is the golden beetle, scarabæus auratus; it is about the size of the common or black garden-beetle, but of a somewhat flatter shape; and of the most brilliant, varnished, golden-green colour, with the wing-shells varied towards the lower part by a few slight, transverse, white streaks. This beautiful species is not uncommon during the hottest part of

summer, frequenting various plants and flowers; its larva or caterpillar is commonly found in the hollows of old trees, or among the loose dry soil at their roots, and sometimes in the earth of ant-hills. It remains about three years before it changes to a pupa or chrysalis, out of which the insect emerges in a short time afterwards.

This may be sufficient for a general idea of the Linnæan genus scarabæus. It may be added that the species are extremely numerous, and that so great is the singularity of appearance in many kinds, that even the most romantic imagination can hardly conceive a structure of horn or process which is not exemplified in some of the tribe. See Plate Nat. Hist. fig. 353.

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping-instrument.

SCARLET, a beautiful bright red. See Dyeing.

SCARUS, a genus of fishes of the order thoracici. The generic character is, jaws bony, divided in the middle, crenated on the edge; the teeth connate and conglomerate. There are 15 species. The most remarkable are, 1. Scarus Cretensis, Cretan scarus. General length about 12 inches; body broad, sloping, scales extremely large, lateral line ramified on every scale over which it passes. Native of the Mediterranean, and particularly about the coasts of Crete, but is also found in the Indian seas.

2. Scarus rivulatus, rivulated scarus. Native of the Red Sea, observed by Forskal: said to arrive at a great size; scales very small; dorsal and anal fin occasionally recumbent in a channel; tail forked; supposed to feed principally on the different kinds of fuci, and considered as an edible fish; but said to be sometimes productive of disagreeable symptoms from the wounds inflicted by the sharp rays of its dorsal fin.

3. Scarus purpuratus, purpled scarus, an elegant species; in habit allied to the labri: body abruptly lanceolate; the purple stripes on the body serrated at their upper edges: pectoral fins green, and marked at the tip by a large lunated, marginal, black spot: dorsal and anal marked towards the base by a purple stripe; ventral fins blue: tail marked with longitudinal purple spots, and on each side by a purple stripe; shape slightly rounded; lateral line ramified; scales lax, as in the mullet. Native of the Arabian seas; observed by Forskal.

SCAVAGE, a toll or custom antiently exacted by mayors, sheriffs, and bailiffs, of cities and towns-corporate, and of merchant-strangers, for wares exposed and offered to sale within their liberties, which was prohibited by 19 Hen. VII. But the city of London still retains this custom.

SCAVENGERS, two officers annually chosen in every parish in London and its suburbs, by the churchwardens, constables, and other inhabitants, to hire persons called rakers, with carts, to clean the streets, and carry away the dirt and filth, with the ashes and dust from every house. For which purpose a scavenger's tax may be made and levied on the inhabitants, being allowed by the justices of the peace; but it must not exceed fourpence in the pound, on the rent paid for the houses. Persons who refuse to take upon themselves the office of scavenger, forfeit ten pounds. 2 W. and M. c. 2. 1 Geo. I. c. 48. 10 Geo. II. c. 22.

SCENOGRAPHY, in perspective, the perspective representation of a body on a plane; or a description and view of it in all its parts and dimensions, such as it appears to the eye in any oblique view.

This differs essentially from the ichnography and the orthography. The ichnography of a building, &c. represents the plan or ground-work of the building, or section parallel to it; and the orthography the elevation, or front, or one side, also in its natural dimensions; but the scenography exhibits the whole of the building that appears to the eye, front, sides, height, and all, not in their real dimensions or extent, but raised on the geometrical plan in perspective.

In architecture and fortification, scenography is the manner of delineating the several parts of a building or fortress, as they are represented in perspective.

To exhibit the scenography of any body. 1. Lay down the basis, ground-plot, or plan, of the body, in the perspective ichnography; that is, draw the perspective appearance of the plan or basement, by the proper rules of perspective. 2. Upon the several points of the perspective plan, raise the perspective heights, and connect the tops of them by the proper slope or oblique lines. So will the scenography of the body be completed, when a proper shade is added. See Perspective.

SCEPTRE, one of the six new constellations of the southern hemisphere, consisting of seventeen stars. See Astronomy.

SCHÆFFERA, a genus of the tetrandria order, in the diœcia class of plants; and in the natural method ranking with those that are doubtful. The calyx is quadripetalous; the corolla is quadripetalous, quinquepetalous, and often wanting; the fruit is a bilocular berry, with one seed. Of this there are two species, both natives of Jamaica; and grow in the lowlands near the sea, viz. 1. The completa. 2. Lateriflora.

SCHERARDIA, a genus of the monogynia order, in the tetrandria class of plants. The corolla is monopetalous and funnel-shaped; there are two three-toothed seeds.

SCHEUCHZERIA, a genus of the trigynia order, in the hexandria class of plants; and in the natural method ranking under the fifth order, tripetaloideæ. The calyx is sexpartite; there is no corolla, nor are there any styles; there are three inflated and monospermous capsules. Eleven species.

SCHIEFERSPAR, a mineral ranked among the species of carbonat of lime. Colour greyish, reddish, greenish, or yellowish white. Found massive: texture curve foliated: brittle: feels unctuous, and may be scratched by the nail. Specific gravity 27. It is composed of carbonat of lime, with a small portion of silica and oxide of iron.

SCHINUS, a genus of the decandria order, in the diœcia class of plants; and in the natural method ranking under the 43rd order, dumosæ. The male calyx is quinquefid; the petals five. The female flower is the same as in the male; the berry tricoccous. There are two species, of South America.

SCHIROCCO. See Wind.

SCHISTUS, in mineralogy, a name given to several different kinds of stones, but more especially to some of the argillaceous kind; as, 1. The bluish purple schistus, schistus tegularis, or common roof-slate. This is so soft, that it may be slightly scraped with the nail, and is of a very brittle lamellated texture, of the specific gravity of 2.876. It is fusible per se in a strong heat, and runs into a black scoria. By a chemical analysis it is found to consist of 26 parts of argillaceous earth, 46 of silex, 8 of magnesia, 4 of lime, and 14 of iron. The dark-blue slate, or schistus scriptorius, contains more magnesia and less iron than the common purple schistus, and effervesces more briskly with acids. Its specific gravity is 2.701. 2. The pyritaceous schistus is of a grey colour, brown, blue, or black; and capable of more or less decomposition by exposure to the air, according to the quantity of pyritous matter it contains, and the state of the iron in it. The aluminous schistus belongs to this species. 3. The bituminous schistus is generally black, and of a lamellated texture, of various degrees of hardness, not giving fire with steel, but emitting a strong smell when heated, and sometimes without being heated. M. Magellan mentions a specimen which burns like coal, with a strong smell of mineral bitumen, but of a yellowish brown, or rather dark ash-colour, found in Yorkshire. This kind of schistus does not show any white mark when scratched, like the other schistus.

SCHLEFFLERA, a genus of the class and order pentandria decagynia. The calyx is five-toothed; corolla five-petalled; capsule eight or ten celled; seeds solitary, semicircular. There is one species, of New Zealand.

SCHMIDELIA, a genus of the digynia order, in the octandria class of plants. The calyx is diphyllous; the corolla tetrapetalous; the germina pedicellated, and longer than the flower. There is one species, a tree of the East Indies.

SCHOENUS, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the third order, calamariæ. The glumes are paleaceous, univalved, and thick-set; there is no corolla, and only one roundish seed between the glumes. There are 41 species.

SCHOLIUM, a note, annotation, or remark, occasionally made on some passage, or proposition, of an old author. This term is much used in geometry, and other parts of mathematics, where after demonstrating a proposition, it is customary to point out how it might be done some other way, or to give some advice, or precaution, in order to prevent mistakes, or add some particular use or application of it.

SCHOTIA, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 33d order, lomentaceæ. The calyx is semiquinquefid; the corolla has five petals, which are equal; the tube is turbinated, carnous, and persistent; the legumen pedicellated, and contains two seeds. There is only one species, viz. the speciosa, or African lignum vitæ.

SCHRADERA, a genus of the class and order hexandria monogynia. The calyx is superior; corolla five or six-cleft; stigmas two; berry one-seeded. There are two species, parasites of the West Indies.

SCHREBERA, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is quinquepartite; the corolla funnel-shaped, with the filaments in the throat, and having each a scale at the base. There is one species, a tree of the East Indies.

SCHWALBEA, a genus of the class and order didynamia angiospermia. The calyx is four-cleft; the upper lobe very small; the lowest very large and emarginate. There is one species, of North America.

SCHWENKFELDIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is quinquefid; the corolla funnel-shaped; the stigma parted into five; the berry quinquelocular, with a number of seeds. Of this there are three species, viz. 1. Cinerea; 2. Aspera; 3. Hirta. The two first are natives of Guiana, the other of Jamaica. The leaves of all of them are remarkably rough, and stick to the fingers or clothes.

SCHWENKIA, a genus of the monogynia order, in the diandria class of plants. The corolla is almost equal, plaited at the throat, and glandulous; there are three barren stamina; the capsule bilocular and polyspermous. There is one species.

SCIÆNA, a genus of fishes of the order thoracici. The generic character is, head scaly; dorsal fins two, seated in a furrow, into which they may occasionally withdraw; gill-membrane six-rayed. There are two divisions in this genus, 1. with divided or lunated tail; 2. with even or rounded tail. There are twenty species. The most remarkable are: 1. Sciæna cirrosa, bearded sciæna. Habit that of a carp; length from one to two feet; colour pale yellow, brownish on the back, and marked on each side by many obliquely longitudinal dusky-blue lines, which assume a slightly silvery cast towards the abdomen: upper lip obtuse, and longer than the lower; teeth small; first dorsal fin triangular, and pale brown; the second white, with a brown stripe: pectoral, ventral, and caudal, dusky; anal red; tail slightly lunated: at the base of the gill-covers a black spot, and beneath the chin a short fleshy beard: native of the Mediterranean and other seas: known to the antient Greeks and Romans, by whom it was held in considerable estimation as a food.

2. Sciæna labrax, basse sciæna. Habit of a salmon; size considerable, growing, according to some authors, to the length of several feet: colour blueish silvery, with a dusky cast on the back: scales rather small; eyes reddish; mouth and gill-covers tinged with pale red; tail slightly forked; lateral line nearly straight: native of the Mediterranean and northern seas, and often entering rivers; known to the antients by the names of labrax and lupus, and much esteemed as a food, particularly by the Romans.

SCIATICA. See MEDICINE.

SCILLA, the *squill*, in botany, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous and deciduous; the filaments filiform. There are 22 species. The most remarkable is the maritima, or sea-onion, whose roots are used in medicine. Of this there are two sorts, one with a red, and the other with a white root; which are supposed to be accidental varieties, but the white are generally preferred for medicinal use. The roots are large, somewhat oval-shaped, composed of many coats lying over each other like onions; and at the bottom come out several fibres. From the middle of the root rise several shining leaves, which continue green all the winter, and decay in the spring. Then the flower-stalk comes out, which rises two feet high, and is naked half-way, terminating in a pyramidal thyrse of flowers, which are white, composed of six petals, and spread open like the points of a star. This grows naturally on the sea-shores, and in the ditches where the salt water naturally flows with the tide, in most of the warm parts of Europe, so cannot be propagated in gardens; the frost in winter always destroying the roots, and for want of salt water they do not thrive in summer. The root is very nauseous to the taste, intensely bitter, and so acrimonious that it ulcerates the skin if much handled. Taken internally, it powerfully stimulates the solids, and promotes urine, sweat, and expectoration. If the dose is considerable, it proves emetic, and sometimes purgative. The principal use of this medicine is where the primæ viæ abound with mucous matter, and the lungs are oppressed by tenacious phlegm.

SCIOPTIC, a sphere, or globe of wood, with a circular hole or perforation, wherein a lens is placed. It is so fitted that, like the eye of an animal, it may be turned round every way, to be used in making experiments in a darkened room. See OPTICS.

SCIRE FACIAS, is a judicial writ, and properly lies after a year and a day after judgment given; whereby the sheriff is commanded to summon or give notice to the defendant, that he appear and shew cause why the plaintiff should not have execution. 1 Inst. 290. A scire facias is deemed a judicial writ, and founded on some matter of record, as judgments, recognizances, and letters patent, on which it lies to enforce the execution of them, or to vacate or set them aside; and though it is a judicial writ of execution, yet it is so far in nature of an original, that the defendant may plead to it, and is in that respect considered as an action; and therefore it is held, that a release of all actions, or a release of all executions, is a good bar to a scire facias. See Rol. Abr.

SCIRPUS, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the third order, calamariæ. The glumes are paleaceous, and imbricated all round. There is no corolla, and only one beardless seed. There are 69 species, rushes of the East Indies.

SCIRRHUS. See SURGERY.

SCIURUS, SQUIRREL, a genus of quadrupeds of the order glires: the generic character is, upper front-teeth cuneated, lower sharp; grinders in the upper jaw five on each side, in the lower four; clavicles in the skeleton; tail (in most species) spreading towards each side. The animals composing this elegant genus are remarkable for the liveliness of their disposition, the celerity of their motions, and the general beauty and neatness of their appearance. They inhabit woods, live entirely on vegetable food, and take up their residence in the hollows of trees, where they prepare their nests. Some species are furnished with an expansile lateral skin, reaching from the fore legs to the hind; by the help of which they are enabled to spring to a greater distance than the rest of the genus, and to transport themselves occasionally from tree to tree; but this momentary support in air is all that they are capable of; and though called, from this circumstance, flying squirrels, they are unable to continue that action in the manner of bats. The species of squirrels enumerated in the twelfth edition of the Systema Naturæ of Linnæus amounted to no more than eleven; but such has been the spirit of research among modern naturalists, that the number is now increased to near thirty. The most noted are,

1. Sciurus maximus, great squirrel. Of all the species yet discovered, this is the largest, being equal in size to a cat. It is a native of India, and was first described by Mons. Sonnerat, who informs us that it is found in the Malabar country, and especially about the mountains of Cardamone, where it feeds on fruits, and is particularly fond of the milk of the cocoa-nut, which it pierces, when ripe, in order to obtain the liquor. The fur on the whole animal is long and full; the top of the head, ears, back, and sides, are ferruginous, and a small band of a similar colour commences beneath each ear, passing along the neck towards the sides. This animal, according to Sonnerat, is easily tamed, and is called about the coasts of Malabar by the name of the great wood-rat. See Plate Nat. Hist. fig. 354.

2. Sciurus vulgaris, common squirrel. The general appearance and manners of this species are so well known that it is unnecessary to particularize them. It is a native of almost all parts of Europe as well as of the northern and temperate parts of Asia, but is observed to vary in the cast of its colours in different climates, and in the northern regions becomes grey in winter; it also varies occasionally in size. The general measure of the European squirrel seems to be about eight inches from nose to tail, and of the tail about seven. In the spring these animals seem peculiarly active, pursuing each other among the trees, and exerting various efforts of agility. During the warm summer nights they may be also observed in a similar exercise. They seem, as Buffon observes, to dread the heat of the sun; for during the day they commonly remain in their nests, making their principal excursions by night. Their habitation is so contrived as to be perfectly clean, warm, and impenetrable by rain, and is composed of moss, dried leaves, &c. and situated between the fork of two branches; it has only a small aperture near the top, which is of a conical form, so as to throw off the rain. The young are generally three or four in number, and are produced about the middle of summer, or sometimes earlier.

The squirrel feeds on the buds and young shoots of trees, and is said to be particularly fond of those of the fir and pine; it also collects great quantities of nuts, which it deposits in the hollows of trees for its winter food, together with beech-mast, acorns, &c. Dr. Pallas also assures us, that those of Siberia collect various kinds of fungi for this purpose. In a state of captivity, nuts form its principal food, but it will also eat a great variety of fruits and other vegetable substances, and is delighted with sugar and various sweets.

In some parts of Siberia the squirrel is found entirely white, with red eyes. About lake Baikal it is often entirely black, or black with the belly white; and in some parts of Europe, and particularly in our own country, it is occasionally found with the tail milk-white, and all the other parts of the usual colour.

3. Sciurus cinereus, grey squirrel. This species is confined to North America, in many parts of which it is extremely common, and in its general form, as well as in its way of life, resembles the European squirrel. It is a large and elegant animal, being of the size of a half-grown rabbit, and measuring about twelve inches to the tail; different individuals, however, vary somewhat in point of size. The whole animal is of an elegant pale-grey, with the insides of the limbs and the under parts of the body white. This animal is said to be found in Canada, Pennsylvania, Virginia, and other American districts; though, according to Mr. Pennant, it scarcely extends farther north than New England. Mr. Pennant also allows that it is a native of South as well as North America. In the latter it is in some years so extremely numerous as to do incredible damage to plantations, especially those of maize or Indian corn; for which reason it is one of the proscribed animals among the colonists. This species resides principally among trees, in the hollows of which it makes its nest, with straw, moss, &c. feeding on acorns, fir-cones, maize, &c. as well as on fruits of various kinds. It is said to amass great quantities of provision for winter, which it deposits in holes which it prepares beneath the roots of trees, &c. It is a difficult animal to kill, changing its place on the trees with such expedition, as generally to elude the shot of the quickest marksman.

4. Sciurus striatus, the striped squirrel, is a native of the northern regions of Asia, and of several of the colder parts of North America; it has also been found, though very rarely, in some parts of Europe, and differs from the major part of the squirrel tribe in its manner of life, which rather resembles that of the dormouse, being chiefly passed in subterraneous retreats or burrows, the apartments of which are filled with various stores of acorns, nuts, grain, &c. collected for winter use. It also resembles some of the murine tribe, in being provided with cheek-pouches, for the temporary reception of food: a particularity not to be found in any other species of squirrel. Its general length is about five inches and a half, and of the tail rather more. Its colour on the upper parts is a reddish brown, and on the under white; down the ridge of the back runs a black streak; and on each side the body are two others, the included space between each being of a pale-yellow tinge.

These animals are, according to the observations of Dr. Pallas, extremely common in Siberia, inhabiting the maple and birch woods of that country, and generally forming their nests or burrows near the root of some tree: they are never known to ascend trees in the manner of other squirrels, unless suddenly surprised or pursued, when they climb with great expedition, and conceal themselves among the branches; they collect their stores during the autumnal season, and on the setting in of winter conceal themselves in their burrows, the entrances of which they stop; and pass the greatest part of the rigorous season in sleep, and in feeding on their collected stores; but if, by an unusual continuance of severe weather, their provisions happen to fail, they then sally out in quest of fresh supplies, and occasionally make their way into granaries, and even into houses. In the choice of their food they are remarkably nice, and have been observed, after filling their pouches with rye, to fling it out on meeting with wheat, and replace it with the superior grain. They are of a wild nature, and are by no means easily reconciled to a state of captivity; continuing timid, and shewing no symptoms of attachment to their owners. They are taken merely on account of their skins, which, though forming but a slight or ordinary fur, have a very pleasing appearance, when properly disposed, and are said to be chiefly sold to the Chinese.

5. Sciurus volans, common flying squirrel. This highly elegant animal is the only flying squirrel yet discovered in Europe, where it is extremely rare, being found chiefly in the most northern regions, as in Finland, Lapland, &c. It also occurs in some districts of Poland. In many parts of Asia it is far more common, and abounds in the birch and pine woods of Siberia in particular. It appears to have been confounded by authors with the Virginian flying squirrel (S. volucella), but is a totally distinct species. Its colour on the upper parts is an elegant pale or whitish grey, and on the under parts milk-white. Its general size is inferior to that of a common squirrel, measuring about six inches and a quarter to the tail, which is shorter than the body, thickly furred, of a slightly flattened form, and rounded at the extremity. The flying squirrel generally resides in the hollows of trees towards the upper part; preparing its nest of the finer mosses. It is a solitary animal, and is only seen in pairs during the breeding-season. It rarely makes its appearance by day, emerging only at the commencement of twilight, when it may be seen climbing about the trees, and darting with great velocity from one to the other. The colour of its upper part so much resembles that of the pale silvery bark of the birch-trees which it frequents, that it is by no means easy to distinguish it, while engaged in climbing about during its evening exercise. It feeds chiefly on the young shoots, buds, and catkins of the birch, as well as on those of the pine, &c. In winter it continues in its nest, coming out only in mild weather; but does not become torpid during that season.

This animal readily springs to the distance of twenty fathoms or more, and by this motion conveys itself from the top of one tree to the middle part of that to which it directs its flight, which is always slightly downwards. It very rarely descends to the surface, and, when taken, and placed on the ground, runs or springs somewhat awkwardly, with its tail elevated, and as soon as it gains a tree, instantly begins to climb it with great activity; sometimes elevating, and sometimes depressing its tail. If thrown from the top of a tree, it immediately spreads its membranes, and, balancing itself, endeavours to direct its motion by the assistance of the tail. The young are produced about the beginning or before the middle of May, and are two, three, and sometimes four, in number; they are at first blind, and nearly void of hair; and the parent fosters them by covering them with her flying-membrane; leaving her nest only at the approach of evening, and carefully concealing the young with the moss of the nest.

SCIURUS, a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is quinquedentate; the corolla bilabiated; the filaments are barren; the capsules five, and joined together; bivalved, unilocular, with one seed. Of this there is one species, viz. aromatica, a native of Guiana.

SCLERANTHUS, Knawel, a genus of the digynia order, in the dodecandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is monophyllous; there is no corolla; there are two seeds contained in the calyx: There are three species.

SCLEROCARPUS, a genus of the class and order syngenesia polygamia æqualis. The calyx is six-leaved; recept. chaffy. There is one species, a herb of the Cape.

SCLEROTICA, in anatomy, one of the tunics, or coats, of the eye. See Optics, &c.

SCOLD. A common scold is a public nuisance to her neighbourhood, for which offence she may be indicted.

SCOLEX, a genus of vermes intestina. The generic character is, body gelatinous, variously shaped, brandished on the fore part, and pointed behind; sometimes linear and long; sometimes wrinkled and short, round, flexuous, and depressed; head protrusile, and retractile. There are two species, found in the intestinal mucus of the turbot, &c. invisible to the naked eye.

SCOLIA, a genus of insects of the order hymenoptera: the generic character is, mouth with a curved sharp mandible, crenate within; jaw compressed, projecting entire, and horny; tongue inflected, trifid, very short; lips projecting, membranaceous at the tip, and entire: feelers four, equal, short, filiform, in the middle of the lip; antennæ thick, filiform, the first joint longer. There are 40 species.

SCOLOPAX, in ornithology, a genus belonging to the order of grallæ. The back is cylindrical, obtuse, and longer than the head; the nostrils are linear; the face is covered, and the feet have four toes. There are eighteen species, of which the following are the principal:

1. The arquata, or curlew, frequents our sea-coasts and marshes in the winter-time in large flocks, walking on the open sands; feeding on shells, frogs, crabs, and marine insects. In summer they retire to the mountainous and unfrequented parts of the country, where they pair and breed. Their eggs are of a pale olive-colour, marked with irre-

gular but distinct spots of pale brown. Their flesh is rank and filthy, notwithstanding an old English proverb in its favour. Curlews differ much in weight and size; some weighing 37 ounces, others not 22; the length of the largest to the tip of the tail, 25 inches; the breadth, three feet five inches; the bill is seven inches long; the head, neck, and coverts of the wings are of a pale brown; the middle of each feather black; the breast and belly white, marked with narrow oblong black lines; the back is white, spotted with a few black strokes; the quill-feathers are black, but the inner webs spotted with white; the tail is white, tinged with red, and beautifully barred with black; the legs are long, strong, and of a blueish grey colour; the bottoms of the toes flat and broad, to enable it to walk on the soft mud, in search of food.

2. The phæopus, or whimbrel, is much less frequent on our shores than the curlew; but its haunts, food, and general appearance, are much the same. It is observed to visit the neighbourhood of Spalding (where it is called the curlew knot) in vast flocks in April, but continues there no longer than May, nor is it seen there any other time of the year; it seems at that season to be on its passage to its breeding-place. The specific difference is the size, this never exceeding the weight of twelve ounces.

3. The rusticola, or woodcock, during summer inhabits the Alps of Norway, Sweden, Polish Prussia, the march of Brandenburg, and the northern parts of Europe; they all retire from those countries in the beginning of winter, as soon as the frosts commence, which force them into milder climates, where the ground is open, and adapted to their manner of feeding. They live on worms and insects, which they search for with their long bills in soft grounds and moist woods. Woodcocks generally arrive here in flocks, taking advantage of the night or a mist; they soon separate; but, before they return to their native haunts, they pair. They feed and fly by night, beginning their flight in the evening, and return the same way or through the same glades to their day retreat. They leave England the latter end of February, or beginning of March; not but they have been known to continue here accidentally.

4. The gallenago, or common snipe, is well known. Its usual weight is about four ounces. The jack snipe (which is by some thought a different species) does not weigh above half as much.

5. The calidris, or red-shank.

6. The glottis, or green-shank.

7. The œgocephala, or godroit.

SCOLOPENDRA, Centipede, a genus of insects of the order aptera: the generic character is, antennæ setaceous; body depressed; legs numerous, equalling the number of segments of the body on each side; feelers two, setaceous. The larger species of the genus scolopendra, found only in the hotter regions of the globe, are insects of a formidable appearance, and possess the power of inflicting severe pain and inflammation by their bite. Of these one of the most conspicuous is the scolopendra morsitans, a native of many parts of Asia, Africa, and South America. Its length is sometimes not far short of ten inches; its colour is yellowish brown, the legs and under parts of the body being much paler; the head is armed on each side with a very large curved fang, of the same strong or horny nature as those of the aranea avicularia, but placed in a different direction, the two fangs meeting horizontally when in action; these fangs are furnished on the inside, near the tip, with an oblong slit, through which, during the act of wounding, an acrimonious or poisonous fluid is discharged; the eyes are several in number on each side the head, and are placed in a small oval groupe; the legs are twenty on each side the body, and the tail is terminated by a pair of processes, which perfectly resemble the rest of the legs, except that they are larger, and have the first joints strongly spined or muricated on the inside. These horrible insects are said to be chiefly found in woods, but, like the small European species, they are occasionally seen in houses, and are said to be so common in some particular districts that the inhabitants are obliged to place the feet of their beds in vessels of water, in order to prevent their attacks during the night.

2. Scolopendra Plumieri, or Plumier's scolopendra, is of much greater length than the former, sometimes measuring a foot and a half. According to the description and figure of Seba, the body consists of thirty-two joints, exclusive of the head and tail.

3. Scolopendra forficata, is a very common insect, and is met with in similar situations with the oniscus asellus and armadillo; it is an animal of swift motion, and is furnished with fifteen legs on each side; its colour is a polished chesnut-brown, somewhat paler beneath, and its usual length an inch and a half. See Plate Nat. Hist. fig. 355.

4. Scolopendra electrica is, like the former, an inhabitant of damp situations, and not unfrequently makes its appearance in houses; its general length is about an inch and a half, and its diameter scarcely more than the tenth of an inch, being of an extremely long and slender form; its colour is a dusky brown, with the legs yellowish; these are about seventy on each side. The motions of this insect are tortuous and undulatory, seldom continuing long in the same direction; it is possessed of a high degree of phosphoric splendour, which however seems to be only exerted when the animal is pressed or suddenly disturbed, when it diffuses a beautiful smaragdine light, so powerful as not to be obliterated by two candles on the same table. It is also tenacious of life, remaining seemingly uninjured for a great many days in the closest confinement.

5. Scolopendra subterranea so much resembles the former, that it might be easily confounded with it; it is however of a still more slender form, and of a much paler colour, viz. a light yellow brown; it is found in damp places, and often under ground; is not possessed of any phosphoric splendour, nor is it capable of surviving many hours in a state of confinement, unless placed in a very moist situation.

The scolopendræ are oviparous animals, and the young, at their first exclusion, are furnished only with a few feet on each side; acquiring after a certain period, the legitimate number peculiar to their species, of which there are eleven.

SCOLOPIA, a genus of the tetrandria monogynia class and order. The calyx is inferior, three or four-parted; corolla three or four-petalled; berry one-celled, six-seeded; seeds arilled. There is one species, the thorny cinnamon of Ceylon.

SCOLOSANTHUS, a genus of the class and order tetrandria monogynia. The calyx is four-cleft; corolla tubular; drupe one-seeded. There is one species, a shrub of Santa Cruz.

SCOLYMUS, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; the calyx imbricated and prickly, without any pappus. There are three species.

SCOMBER, Mackrel, a genus of fishes of the order thoracici; the generic character is, body oblong, smooth, sometimes carinated by the lateral line; finlets (in most species) above and below, towards the tail. There are 22 species, of which the most remarkable are:

1. Scomber scomber, common mackrel. This beautiful fish is a native of the European and American seas, generally appearing at stated seasons, and swarming, in vast shoals, round particular coasts. Its great resort, however, seems to be within the Arctic circle, where it resides in innumerable troops, grows to a larger size than elsewhere, and is supposed to find its favourite food, consisting chiefly of marine insects, in far greater plenty than in warmer latitudes. During the severity of the northern winter it is said to lie imbedded in the soft mud, beneath the vast crusts of ice surrounding the polar coasts, being thus sufficiently protected from the effects of frost; and, on the return of spring, is generally believed to migrate in enormous shoals, of many miles in length and breadth, and to visit the coasts of more temperate climates in order to deposit its spawn. Its route has been supposed nearly similar to that of the herring, passing between Iceland and Norway, and proceeding towards the northern part of our own island, where a part throws itself off into the Baltic, while the grand column passes downwards, and enters the Mediterranean through the straits of Gibraltar.

This long migration of the mackrel, as well as of the herring, seems at present to be greatly called in question; and it is thought more probable that the shoals which appear in such abundance round the more temperate European coasts, in reality reside during the winter at no very great distance; immersing themselves in the soft bottom, and remaining in a state of torpidity; from which they are awakened by the warmth of the returning spring, and gradually recover their former activity. At their first appearance their eyes are observed to appear remarkably dim, as covered with a kind of film, which passes off as the season advances, when they appear in their full perfection of colour and vigour.

The shape of the mackrel is highly elegant, and it is justly considered as one of the most beautiful of the European species. Its merit as an article of food is universally established, and it is one of those fishes which have maintained their reputation through a long succession of ages; having been highly esteemed by the antients, who prepared from it the particular condiment or sauce known to the Romans by the title of garum, and made by salting the fish, and after a certain period straining the liquor from it. This preparation, once so famous, has been long superseded by the introduction of the anchovy for similar purposes.

2. Scomber thynnus, tunny. The tunny is a very large species, growing to the length of eight, or even ten feet, but much more commonly seen of about the length of two feet. It is an inhabitant of the Mediterranean, Northern, Indian, and American seas, and is of a gregarious nature, frequently assembling in large shoals. It is an animal of great strength and fierceness, preying on all kinds of smaller fishes, and is said to be the peculiar persecutor of the mackrel and the flying-fish. Its flesh, though rather coarse, was much esteemed by the antient Greeks, and Romans, who established their tunny-fisheries as in modern times, on many parts of the Mediterranean coasts, where this fish still continues to be taken in great plenty, more especially round the island of Sicily. In the British seas it is rarely observed in shoals; the individuals which occur being rather considered as accidental stragglers. Mr. Pennant records an instance of one which he saw on the northern coasts of Scotland, weighing 460 pounds, and measuring seven feet ten inches in length. Much larger specimens, however, are occasionally taken in the Sicilian sea. In the Indian ocean this species is said to be seen of an enormous size, and to assemble in vast shoals.

The tunny-fishery is of equal importance to the inhabitants of the Mediterranean coasts as the herring-fishery to those of the more northern parts of Europe. The smaller fishes are chiefly sold fresh, while the larger are cut in pieces and salted, and barrelled up for sale.

The general colour of the tunny is a dark or dull blue on the upper parts, and silvery with a cast of flesh-colour on the sides and abdomen.

3. Scomber trachurus, shad, horse-mackrel, inhabits the European, American, and Pacific seas. See Plate Nat. Hist. fig. 356.

SCOPARIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadripartite; the corolla the same, and rotaceous; the capsule unilocular, bivalved, and polyspermous. There are three species.

SCOPOLIA, a genus of the octandria order, in the gynandria class of plants; and in the natural method ranking under the 11th class, sarmentaceæ. The calyx is diphyllous; the corolla quadrifid; the antheræ coalesce in two columns, one placed above the other. There are two species.

SCORE, in music, the original and entire draught, or its transcript, of any composition. In the score all the parts of the piece are ranged perpendicularly under each other, so that the eye, catching the corresponding bars of the several staves, sees at a glance the whole construction and design of the harmony.

As in this disposition, one single line of music comprehends as many staves as there are parts; these staves are held together by a brace drawn down the margin at the beginning of the line.

The use of the score is indispensable in composition; to the conductor of any performance it is also highly requisite, in order to his knowing whether each performer follows his part, and to enable him to supply any accidental omission with the piano-forte, or organ, at which he presides.

SCORIA, or DROSS, is that mass which is produced by melting metals and ores, and when cold is brittle, and not unsoluble in water; being properly a kind of glass.

SCORING, the art of forming a score by collecting and properly arranging under each other the several detached parts of any composition.

SCORPÆNA, a genus of fishes of the order thoracici: the generic character is, head large, aculeated, cirrhose, obtuse, without scales, subcompressed; eyes placed near each other; teeth in the jaws, palate, and throat; gill-membrane seven-rayed: body fleshy; dorsal fin single, with the rays of the fore part spiny. There are nine species; the most remarkable are:

1. Scorpæna porcus, porcine scorpæna. The genus scorpæna is distinguished by a peculiar uncouthness of appearance; the head, in some species, being abruptly truncated in front, of vast size, and armed with various protuberances and spines. Among the most common of the European species is the scorpæna porcus, which is frequently seen in considerable numbers in various parts of the Mediterranean, where it chiefly frequents the shores, lying in ambush among stones, sea-weeds, &c. and preying on the smaller fishes and sea-insects; the head is large; the mouth wide, with many rows of small sharp teeth; the eyes large; the gill-covers armed with strong spines intermixed with cirri; the body covered with small rough scales, of a dusky colour, varied with black on the back, and beneath pale, with a reddish cast; the dorsal fin is furnished with very strong spiny rays, which the fish, when caught, erects, and thus wounds its adversary; its general length is about twelve or fifteen inches.

2. Scorpæna scrofa, rufous scorpæna, in general appearance so nearly allied to the preceding, that at first view it might be mistaken for the same species; but differs in its superior size, as well as in its larger scales; and particularly in having several cirri or processes disposed along the lateral line; the colour also is rather rufous than brown as in the former kind. Of this species it is reported that it preys not only on the smaller fishes, but even occasionally seizes on such of the marine birds as happen to swim in its way. It grows to a very considerable size, and is said to have been seen of the length of four feet; it must consequently prove a very formidable enemy to the smaller marine animals. Notwithstanding its forbidding appearance, it is considered as an edible fish.

3. Scorpæna horrida, horrid scorpæna. Of all the species yet discovered, the present exhibits the most uncouth and forbidding appearance, resembling rather some imaginary monster of deformity than any regular production of nature. The head is very large, perfectly abrupt in front, and marked by numerous tubercles, depressions, and spines; on the top is a semilunar cavity; the mouth opens from the upper part, and is large and of a shape somewhat resembling a horseshoe, and when closed the lower jaw is in a perpendicular direction; both jaws are armed with numerous small teeth; and the upper is furnished with three cirri, viz. one on each side, and one in the middle. The general colour of this hideous fish is a ferruginous brown, deepest on the upper parts; the abdomen being much paler. It is a native of the Indian seas, and measures twelve or fifteen inches in length. See Plate Nat. Hist. fig. 357.

4. Scorpæna volitans, flying scorpæna, a fish of a highly singular appearance: general length ten or twelve inches; colour brownish-yellow, variegated by very numerous, deep brown, transverse stripes; native of the rivers of Japan, Amboina, &c. and considered as an excellent food; it probably uses its pectoral fins for the purposes of occasional flight, like the fishes of the genus exocœtus and some of the triglæ.

5. Scorpæna didactyla, didactyle scorpæna. General length about a foot; form extremely grotesque; general colour dusky brown, varied above by transverse yellow streaks, and beneath by roundish spots of the same colour; skin destitute of scales; head depressed, and furnished on different parts with several abrupt fleshy cirri; eyes large, and situated on two approximated protuberances; snout truncated, and marked on the sides by several angular wrinkles, as are also the lower parts of the gill-covers; lower jaw longer than the upper; tongue prominent, and marked with yellow granules and black streaks; on the lower mandible are strong fleshy beards; lateral line near the back; fins furnished with many far-projecting radii, as in the volitans and antennata: it preys on the smaller fishes, sea-insects, &c. and, notwithstanding its forbidding appearance, is considered as an excellent fish for the table.

SCORPIO, SCORPION, a genus of insects of the order aptera; the generic character is, body ovate-elongated; legs eight, besides two frontal claspers; eyes eight, three on each side the thorax, and two on the back: tail elongated, jointed, and terminated by a curved piercer; combs or toothed processes two, situated beneath, between the thorax and abdomen. The malignant genus scorpio (about six), so proverbially remarkable for the effect of its poisonous sting, seems chiefly confined to the warmer parts of the globe, and may be considered as a stranger to the northern regions. 1. The common Italian scorpion usually measures something more than an inch in length from the head to the setting on of the tail; but, if measured from the tips of the claspers to the tip of the tail, about three inches; its colour is brown, with considerable variation in different individuals, some inclining to a reddish, and some to a yellowish cast. This animal is found in neglected places, beneath boards, stones, &c. and frequently makes its appearance in houses: its sting is painful, but seldom productive of any very serious consequences, and the usual remedy is sweet oil, well rubbed on the punctured part. Like the rest of the genus, this insect preys on other insects, and particularly on spiders.

2. Scorpio Americanus or the American scorpion, is of somewhat smaller size than the preceding, and of a more slender or lengthened form; its colour is a yellowish brown. It is a native of many parts of America.

3. The largest and by far the most formidable of the genus, is the scorpio Afer of Linneus, or great African scorpion. This species is of so large a size as often to measure four inches from the head to the beginning of the tail, and ten inches if measured from the tip of the claspers to that of the tail. Its colour is a dark brown, inclining to yellow beneath, and in the interstices of the joints; and the claspers have often a reddish cast. This species is found in many parts of Africa, where it is held in great dread; the effect of its sting producing very severe symptoms, and sometimes even proving fatal.

The poison of the scorpion is evacuated through two very small oblong foramina situated on each side the tip of the sting. It is well known that a diversity of opinion has subsisted among authors relative to this particular. The celebrated Redi, assisted by the best microscopes he could procure, was not able to detect any orifice, though he was well convinced of the existence of such, from observing a minute drop of poison exsude from near the tip. Others have denied the existence of any foramen; but Vallisneri and Lewenhoek have properly described two foramina, viz. one on each side; so that the sting of the scorpion can with greater facility discharge its poisonous fluid than that of any other insect. A third foramen is said to have been sometimes observed.

The part in scorpions which is situated beneath the breast, bearing the appearance of two minute combs, has been fixed upon by Linnæus as a criterion of the species; the number of teeth, however, varying occasionally in the same species, renders this character uncertain. The use of these organs remains as yet uninvestigated.

Scorpions are viviparous insects, producing a very considerable number of young at once; these are at first entirely white, but acquire their dusky colour in the space of a few days. They are observed to cast their skin from time to time, in the manner of spiders. There are 10 species.

Scorpio. See Astronomy.

SCORPION, in the antient art of war, an engine chiefly used in the defence of the walls of fortified places, by throwing arrows, fireballs, or great stones.

Marcellinus describes the scorpion as consisting of two beams bound together by ropes. From the middle of the two, rose a third beam, so disposed, as to be pulled up and let down at pleasure; and on the top of this were fastened iron hooks, where a sling was hung, either of iron or hemp; and under the third beam lay a piece of hair-cloth full of chaff, tied with cords. It had its name scorpio, because when the long beam or tiller was erected, it had a sharp top in manner of a sting.

To use the engine, a round stone was put into the sling; and four persons on each side, loosening the beams bound by the ropes, drew back the erect beam to the hook; then the engineer, standing on an eminence, gave a stroke with a hammer on the cord to which the beam was fastened with its hook, which set it at liberty; so that hitting against the soft hair-cloth, it struck out the stone with a great force.

SCORPIURUS, Caterpillar, in botany, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The legumen is contracted by incisions on the inside betwixt every two seeds, revoluted round. There are four species; the most remarkable of which is the vermiculata, a native of Italy and Spain. It is an annual plant, with trailing herbaceous stalks, which at each joint have a spatular-shaped leaf with a long footstalk. From the wings of the leaves come out the footstalks of the flowers, which sustain at the top one yellow butterfly-flower, succeeded by a thick twisted pod having the size and appearance of a large caterpillar, whence it had this title. This has long been preserved in the gardens of this country, more on account of its odd shape than for any great beauty.

SCORZA, a mineral of a green-coloured sand, the specific gravity of which is 3.35. It is found in Transylvania, and is composed of

43.00	silica
21.00	alumina
14.00	lime
16.50	oxide of iron
0.25	oxide of manganese
94.75	

SCORZONERA, Viper's grass; a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus plumy; the calyx imbricated, with scales membranaceous on their margins. There are 19 species; the most remarkable is the hispanica, or common scorzonera, which is cultivated in the gardens of this country, both for culinary and medicinal purposes. The root is carrot-shaped, about the thickness of a finger, covered with a dark-brown skin, is white within, and has a milky juice. The stalk rises three feet high, is smooth, and branching at the top. The flowers are of a bright yellow colour.

SCOTLAND. By 5 Anne c. 8, the union of England and Scotland was effected, and the twenty-five articles of union agreed to by the parliaments of both nations, were ratified and confirmed as follows; viz. the succession to the monarchy of Great Britain, shall be the same as was before settled with regard to that of England. The united kingdoms shall be represented by one parliament. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. When England raises 2,000,000*l.* by land-tax, Scotland shall raise 48,000*l.*; the standards of the coin, of weights and measures, shall be reduced to those of England, throughout the united kingdoms. The laws relating to the trade, customs, and the excise, shall be the same in Scotland as in England; but all the other laws of Scotland shall remain in force, though alterable by the parliament of Great Britain; and particularly laws relating to public policy, are alterable at the discretion of parliament; laws relating to private right are not to be altered, but for the evident utility of the people of Scotland. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the house of commons.

The sixteen peers of Scotland shall have all privileges of parliament, and all peers of Scotland shall be peers of Great Britain, ranking next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.

It was formerly resolved by the house of lords, that a peer of Scotland, claiming and having a right to sit in the British house of peers had no right to vote in the election of the sixteen Scotch peers; but it seems now settled, that a Scotch peer, made a peer of Great Britain, has a right to vote in the election of the sixteen Scotch peers; and that if any of the sixteen Scotch peers are created peers of Great Britain, they thereby cease to sit as representatives of the Scotch peerage, and new Scotch peers must be elected in their room.

SCREW. See Mechanics.

Screw, *Archimedes'*. See Hydraulics.

SCRIBING, in joinery, &c. is a term used when one side of a piece of stuff is to be fitted to another that is irregular. In order to make these join close all the way they scribe it, that is, they lay the piece to be scribed close to the other they intend to scribe it to, and opening their compasses to the widest distance these two pieces stand from each other, they bear the point of one of the legs against the side they intend to scribe to, and with the other point draw a line on the stuff to be scribed. Thus they form a line on the irregular piece parallel to the edge of the regular one; and if the stuff is cut exactly to the line, when these pieces are put together they will seem a joint.

SCRIPTURE. All profane scoffing at the holy scripture, or exposing any part thereof to contempt or ridicule, is punishable by fine and imprisonment. 1 Haw. 7.

SCROPHULA. See Medicine.

SCROPHULARIA, Figwort; a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is quinquefid; the corolla almost globose, and resupinated; the capsule bilocular. There are 22 species, of which the most remarkable are: 1. Nodosa, or the common figwort, which grows in woods and hedges. The leaves have a fetid smell and bitter taste. A decoction of them is said to cure hogs of the measles. An ointment made of the root was formerly used to cure the piles and scrophulous sores, but is at present out of practice. 2. Aquatica, water-figwort, or betony. It grows on the sides of rivulets and other wet places, and has a fetid smell, though not so strong as the preceding. The leaves are used in medicine as a corrector of senna, and in powder to promote sneezing. 3. Scorodonia, or balm-leaved figwort. It grows on the banks of rivulets, &c. in Cornwall. 4. Vernalis, or yellow figwort. It grows in hedges in Surry.

SCROTUM. See Anatomy.

SCRUPLE, a weight equal to the third part of a drachm, or to twenty grains. See Weight.

SCULPTURE. Sculpture is an art, in which, by means of taking away, or adding to, matter, all sorts of figures are formed, either in clay or wax, wood, marble or other stones, or metal.

The art of sculpture, in its most extensive sense, comprehends not only carving in wood, stone, or marble, but also enchasing, engraving in all its kinds, and casting in bronze, or lead, wax, and plaister of Paris, as well as modelling in clay, wax, or stucco.

All these are branches of sculpture (of which we shall occasionally make mention); but as they are ranged in their respective practice, under different denominations, we propose to treat here principally of the first branch (and chiefly of carving in stone and marble, which is at present peculiarly considered as the sculptor's art), and of its necessary preliminary, modelling in clay or wax.

Powers of sculpture. Sculpture is not only able, in common with other imitative arts, to express the forms of visible objects and the conceptions of the mind, but it possesses this superior distinction, that by means of its various branches, it is eminently capable of transmitting the most durable records of men's actions to distant ages. Were it not for this art, we should at the present moment be ignorant of every event which has distinguished the course of time in the long period of earthly existence; at least our only knowledge would be gathered from tradition, whose fallacy and inaccuracy are every hour evinced. Without this art, we could form no conjecture of the permanency or variation even of human forms, much less of human passions and taste; nor is it to be forgotten, that the first communication of the laws of God was made to the Israelites by the means of sculpture.

The art of sculpture, like its sister, painting, is imitative, not for the gratification of the eye only, but also of the intellect. It is capable of expressing all forms that fall under our inspection, and also of conveying more select expressions of beauty than are to be found, either by ordinary observation, or are generally united in one body, and which are therefore called ideal forms.

Sculpture, in its confined and proper sense (in which we here proposed to treat of it), divides itself into the carving of bas-reliefs, and of statues, or groups: and its productions may be classed generally, like those of painting, under the respective terms, *historical, allegorical, portraiture,* &c. See Painting.

Bas-relief has been already described (see Relievo). Works of this kind seem to have been invented for the purpose of representing subjects of history or fancy, and may be regarded as a species of painting in stone. They are chiefly used to adorn the pediments, friezes, and pannels of buildings, as well as the pedestals of statues, &c.

Statues are defined to be figures in full or insulated relievo. They are of various descriptions. (See Statues.) They have chiefly been employed for the purposes of religious worship, as among the heathen nations and the Roman-catholics; and for the commemoration of heroic characters, or of men distinguished by any remarkable achievements.

Groups are an assemblage and union of statues, and are generally employed to the same purposes as single statues.

Of the methods of study. The studies necessary for the young sculptor, towards the attainment of his art, are so similar to those which form the painter (with the obvious exceptions arising from the difference of materials employed in the two arts), that very little remains here to be enlarged on, under the head of studies. The principal acquisitions to which the student must direct his endeavours, are, a knowledge of composition, form (including anatomy), and expression; to which, as in painting, must be added the difficult study of grace. These have been already treated of, under the articles painting, design or drawing, and expression. See Drawing, Expression, and Painting.

The method of study most recommended to young sculptors is, to begin with copying, and end with rivalling, the forms of the Greek statues.

——— "Vos exemplaria Græca
Nocturnâ versate manu, versate diurnâ;"

says Du Fresnoy: nor can it be questioned that the sculptors are, generally speaking, the safest guides to the study of nature. But it should not pass unnoticed, that although the forms of the Greek sculpture are, in general, not only more beautiful, but more appropriately so than any other; yet in some instances they have been surpassed by modern sculptors, as in the forms of infants by Fiamingo. See Statues, *antique.*

The method of execution in the Greek statues and other works of sculpture, seems to have been extremely different from that which is generally in use among modern artists. In the antient statues, we frequently find striking proofs of the freedom and boldness that accompanied each stroke of the chisel, and which resulted from the artist's being perfectly sure of the accuracy of the method which he pursued. Even in the most minute parts of the figure, no indication of timorousness or diffidence appears; nothing that can induce us to believe, that the artist feared he might have occasion to correct his strokes. It is difficult to find, even in the second-rate productions of the Grecian artists, any mark of a false stroke or a random touch. This firmness and precision of the Grecian chisel, were certainly derived from a more determined and perfect set of rules, than those of which we are masters.

Besides studying, therefore, in the productions of the Grecian masters, their choice and expression of select nature, whether beautiful, sublime, or graceful, together with that sedate grandeur and simplicity which pervade all their works, the artist will do well to investigate the manual and mechanical part of their operations, as this may lead to the perception of their mode of progress.

It is certain that the antients, almost always formed their first models in wax; to this modern artists have substituted clay, which they prefer on account of its yielding nature, and its sticking in some measure to every thing it touches. We must not, however, imagine from hence, that the method of forming models of wet clay, was either unknown or neglected among the Greeks; on the contrary, it was in Greece that models of this kind were invented. Their author is said by Pliny to have been Dibutades, of Sicyon; and by others Rhæcus, of Samos; and it is well known that Arcelaus, the friend of Lucullus, obtained a higher degree of reputation by his clay models, than by all his other productions.

Clay was, therefore, the first material employed by the Grecians in statuary; an instance of which may be seen in a figure of Alcamenes in bas-relief, in the Villa Albani. The antients used their fingers, and especially their nails, to render certain parts more delicate and lively; hence arose the phrase, ad unguem factus homo, "an accomplished man." It was the opinion of count Caylus, that the antients did not use models in forming their statues. But to disprove this, it is only necessary to mention an engraving on a stone, in the cabinet of Hosch, which represents Prometheus engraving the figure of a man, with a plummet in his hand, to measure the proportions of his model.

As soon as the artist has rendered himself familiarly acquainted with the beauties of the Grecian statues, and formed his taste on the admirable models they exhibit, he may then proceed with advantage and assurance to the imitation of nature. The ideas he has already formed of the perfection of nature, by observing her dispersed beauties combined and collected in the compositions of the antient artists, will enable him to acquire with facility, and to employ with advantage, the detached and partial ideas of beauty which will be exhibited to his view in a survey of nature, in her actual state. When he discovers these partial beauties, he will be capable of combining them with those perfect forms of beauty, with which he is already acquainted. In a word, by having always present to his mind the noble models already mentioned, he will form an accurate judgment of the powers of his art, and will draw rules from his own mind.

There are, however, two ways of imitating nature. In the one, a single object occupies the artist, who endeavours to represent it with precision and truth; in the other, certain lines and features are taken from a variety of objects, and combined and blended into one regular whole. All kinds of copies belong to the first kind of imitation; and productions of this sort must necessarily be executed in a confined and servile manner, with high finishing, and little or no invention. But the second kind of imitation leads directly to the investigation and discovery of true beauty, of that beauty whose perfect idea is only to be found within the mind.

Of the different modes of process in sculpture.—Works of sculpture are performed, either by hollowing or excavating, as in metals, agates, and other precious stones, and in marbles of every description; or by working in relief, as in bas-reliefs in the materials just mentioned, or in statues in metal, clay, wood, wax, marble, or stone.

The excavation of precious stones forms a particular branch of art called intaglio, which, together with the working them in relievo, when the term camayeu is applied to them, belongs to the art of seal-engraving. See Engraving.

The excavation of metals constitutes the art of engraving, in its various branches, on metal of any kind; and its relief comprises enchasing, casting in bronze, &c.

Of the last only, viz. casting in bronze, we take this opportunity of observing, in addition to the account given under the head bronzes, that a highly improved method has lately been put in practice by professor Zauner, an eminent sculptor at Vienna, in the casting of an equestrian statue of the emperor Joseph II. The student may find an accurate detail of Zauner's mode of process, in the Academic Annals of Painting, &c. published by the royal academy of London.

We proceed, as before proposed, to the other more immediate and proper parts of the sculptor's art.

The process of hollowing hard stone or marble, will need no particular description; especially as it is now wholly in disuse, except for the forming of letters in monumental or other inscriptions.

In working in relief, the process is necessarily different, according to the materials in which the work is performed.

As not only the beginning of sculpture was in clay, for the purpose of forming statues, but as models are still made in clay or wax, for every work undertaken by the sculptor; we shall first consider the method of modelling figures in clay or wax.

Few tools are necessary for modelling in clay. The clay being placed on a stand or sculptor's easel, the artist begins the work with his hands, and puts the whole into form by the same means. The most expert practitioners of this art seldom use any other tool than their fingers, except in such small or sharp parts of their work as the fingers cannot reach. For these occasions, they are provided with three or four small tools of wood, about seven or eight inches in length, which are rounded at one end, and at the other flat and shaped into a sort of claws. These tools are called by the French ebauchoirs. In some of these the claws are smooth, for the purpose of smoothing the surface of the model; and in others are made with teeth, to rake or scratch the clay, which is the first process of the tool on the work, and in which state many parts of the model are frequently left by artists, to give an appearance of freedom and skill to their work.

If clay could be made to preserve its original moisture, it would undoubtedly be the fittest substance for the models of the sculptor; but when it is placed either in the fire, or left to dry imperceptibly in the air, its solid parts grow more compact, and the work shrinks, or loses a part of its dimensions. This diminution in size would be of no consequence, if it affected the whole work equally, so as to preserve its proportions. But this is not always the case: for the smaller parts of the figure drying sooner than the larger; and thus losing more of their dimensions in the same space of time, than the latter do; the symmetry and proportions of the work inevitably suffer.

This inconvenience, however, is obviated by forming the model first in clay, and moulding it in plaister of Paris before it begins to dry, and the taking a plaister cast from that mould, and the repairing it carefully from the original work; by which means you have the exact counterpart of the model in its most perfect state; and you have, besides, your clay at liberty for any other work.

In order to model in wax, you must prepare the wax in the following manner: to a pound of wax add half a pound of scammony (some mix turpentine also), and melt the whole together with oil of olives; putting more or less oil as you would have your modelling wax harder or softer. Vermilion is sometimes mixed with this composition, to give it a reddish colour, in imitation of flesh.

In modelling in wax, the artist sometimes uses his fingers, and sometimes tools of the same sort as those described for modelling in clay. It is at first more difficult to model in wax than in clay, but practice will render it familiar and easy.

Of the use of the model. Whatever considerable work is undertaken by the sculptor, whether bas-relief, or statue, &c. it is always requisite to form a previous model, of the same size as the intended work; and the model being perfected, according to the method before described, whether it is in clay, or in wax, or a cast in plaister of Paris, becomes the rule, whereby the artist guides himself in the conduct of his work, and the standard from which he takes all its measurements. In order to regulate himself more correctly by it, he puts over the head of the model an immoveable circle, divided into degrees, with a moveable rule fastened in the centre of the circle, and likewise divided into parts. From the extremity of the rule hangs a line with a lead, which directs him in taking all the points, which are to be transferred from the model to the marble; and from the top of the marble is hung also a line, tallying with that which is hung from the model; by the correspondence of which two lines, the points are ascertained in the marble.

Many eminent sculptors prefer measurements taken by the compasses to the method just described; for this reason, that if the model is moved but ever so little from its level, the points are no longer the same.

This method, however, offers the best means, by which mechanical precision may be attained; but it is manifest, that enough yet remains to exercise and display the genius and skill of the artist. For, first, as it is impossible, by the means of a straight line, to determine with precision the procedure of a curve, the artist derives from this method no certain rule to guide him, as often as the line which he is to describe deviates from the direction of the plumb-line. It is also evident, that this method affords no certain rule to determine exactly the proportion, which the various parts of the figure ought to bear to each other, considered in their mutual relation and connections. This defect, indeed, may be partly supplied by intersecting the plumb-lines by horizontal ones; but even this resource has its inconveniences; since the squares formed by transversal lines that are at a distance from the figure (though they are exactly equal), yet represent the parts of the figure as greater or smaller, according as they are more or less removed from our point of view.

Of sculpture in wood. A sculptor in wood should first take care to choose wood of the best quality, and the most proper for the work which he intends to execute. If he undertakes a large work, requiring strength and solidity, he ought to choose the hardest wood, and that which keeps best, as oak and chesnut; but for works of moderate size, pear or apple-tree serve very well. As even these latter woods are still of considerable hardness, if the work consists only of delicate ornaments, the artist will find it preferable to take some more tender wood, provided it is at the same time firm and close: as, for instance, the Indian tree, which is excellent for this purpose, as the chisel cuts it more neatly and easily than any other wood.

The ancients made statues out of almost every different kind of wood. At Sicyon was a statue of Apollo, made of box; the statue of Diana at Ephesus, was of cedar. As these two sorts of wood are extremely hard and undecaying; and as cedar, in particular, is of such a nature, that, according to Pliny, it ought never to come to an end; the antients preferred them for the images of their divinities.

In the temple built on mount Cyllene in honour of Mercury, Pausanias relates, that there was a statue of that god made of citron-wood, eight feet in height. This wood was also much esteemed.

The cypress likewise, being a wood not apt to spoil, nor to be damaged by worms, was also used for statues; as were the palm-tree, olive, and ebony, of which latter, according to Pliny's account, there was another statue of Diana at Ephesus.

Several other kinds of wood were equally employed for this purpose, even the vine, of which the same author says, there were statues of Jupiter, Juno, and Diana.

Felibien speaks of a French artist at Florence, of the name of Janni, who executed several statues in wood, in a style of finishing equal to marble, and particularly one of St. Rocque, which Vasari considered as a marvellous production.

The beauty of sculpture in wood consists in the tender manner of cutting the wood, free from all appearance of hardness or dryness.

For any work of large dimensions, even though it consists of a single figure, it is better to join together several smaller pieces of wood than to make the whole of a single large piece; which is more able to warp and crack, on account of its not being always dry at heart, although it appears perfectly dry on the outside.

No wood can be properly fit for works of this kind, that has not been cut at least ten years before.

The tools used for sculpture in wood, are the same as those of the joiner or cabinet-maker.

Of sculpture in stone and marble. For sculpture in marble and other stone, the artist must make use of tools of good steel, well tempered, and of strength proportioned to the hardness of the material.

The first thing to be done is, to saw out from a larger block of marble, a block proportioned to the size of the work which is undertaken. After this, the sculptor shapes the gross masses of the forms he designs to represent, by knocking off the superfluous parts of marble with a strong mallet or beel, and a strong steel tool called a point.

When the block is thus hewn out agreeably to the measures previously taken for the performance of the work, the sculptor brings it nearer to the intended form by means of a finer point; and sometimes of a tool called a dog's tooth, having two points, but less sharp than the single one.

After this he uses the gradine, which is a flat cutting tool, with three teeth, but is not so strong as the point.

Having advanced his work with the gradine, he uses the chisel to take off the ridges left by the former tools; and by the dexterous and delicate use of this instrument, he gives softness and tenderness to the figure, till at length, by taking a rasp, which is a sort of file, he brings his work into a proper state for being polished.

Rasps are of several kinds, some straight, some curved, and some harder or softer than others.

When the sculptor has thus far finished his work with the best tools he can procure, wherever certain parts or particular works require polishing, he uses pumice-stone to make all the parts smooth and even. He then goes over them with tripoli, and when he would give a still higher gloss, he rubs them with leather and straw-ashes.

Besides the tools already mentioned, sculptors use also the pick, which is a small hammer pointed at one end, and at the other formed with teeth made of good steel and squared, to render them the stronger. This serves to break the marble, and is used in all places where the two hands cannot be employed to manage the mallet and chisel.

The bouchard, which is a piece of iron, well steeled at the bottom, and formed into several strong and short points like a diamond, is used for making a hole of equal dimensions, which cannot be done with cutting tools. The bouchard is driven with the mallet or beetle, and its points bruise the marble and reduce it to powder. Water is thrown into the hole from time to time, in proportion to the depth that is made, to bring out the dust of the marble, and to prevent the tool from heating, which would destroy its temper; for the free-stone dust on which tools are edged, is only moistened with water to prevent the iron from heating and taking off the temper of the tool by being rubbed dry; and the trepans are wetted for the same reason.

The sculptor uses the bouchard to bore or pierce such parts of his work as the chisel cannot reach without danger of spoiling or breaking them. In using it, he passes it through a piece of leather, which leather covers the hole made by the bouchard, and prevents the water from spirting up in his face.

The other tools necessary for sculpture on marble or stone, are the roundel, which is a sort of rounded chisel; the hougnet, which is a chisel squared and pointed; and various compasses to take the requisite measures.

The process of sculpture in stone is the same as in marble, excepting that the material being less hard than marble, the tools used are not so strong, and some of them are of a different form, as the rasp, the hand-saw, the ripe, the straight chisel with three teeth, the roundel, and the grater.

If the work is executed in free-stone, tools are employed which are made on purpose, as the free-stone is apt to scale, and does not work like hard stone or marble.

Sculptors in stone have commonly a bowl in which they keep a powder composed of plaister of Paris, mixed with the same stone in which their work is executed. With this composition they fill up the small holes, and repair the defects which they meet with in the stone itself.

HISTORY OF SCULPTURE.

Antient art.

The art of sculpture is of such immemorial antiquity, that it has been by some conceived to have had its being from eternity; but without regarding it in this exalted light, St. Augustin has attributed a date to its invention as early as the time of the Protoplast, our common father Adam, who, he affirms, was the inventor of letters. Sculpture, therefore, may trace its pedigree from the infancy of the world, and contend for pre-eminence with the most remote antiquities which it has been employed to celebrate. Josephus, Cedrenus, and some other authors, make mention of some antediluvian sculptures in stone and brick erected at Joppa, which are imagined to have contained the system of sidereal and celestial sciences, and to have remained unhurt for some thousands of years after the universal cataclysm.

Cham, who is supposed to be the same as Zoroaster, is spoken of by the author of the scholastic work on Genesis, as having engraved the liberal arts on fourteen columns, seven of brass, and seven of brick. Serenus also mentions the same circumstance, with this variation, that he says they were engraved on plates of different metals (diversorum metallorum laminis).

Concerning the art of sculpture immediately after the Flood, it is scarcely to be questioned that it was transmitted by Noah to his descendants. About three hundred years after the Deluge, Mercurius Trismegistus reports of himself, that he engraved his most abstruse mysteries on stone, reforming all that had been depraved by Cham. Some of these records were in letters, some in figures and enigmatical characters, probably not unlike to those contained in the stupendous obelisks erected by Misra, the first Egyptian Pharaoh, about four hundred years (according to Kircher) before Moses.

The first mention that is made of the art of sculpture in the writings of Moses, is in the book of Genesis, where we are informed that when Jacob, in obedience to the divine command, was returning to Canaan, his wife Rachel carried along with her the theraphim, or idols, of her father's house. These must certainly have been very small images, since Rachel found it so easy to conceal them from her father, notwithstanding his anxious search; but we are ignorant in what form they were made, or of what materials they were composed. The first persons mentioned in the Bible as artists, are Aholiab and Bezaleel, who formed the cherubim which covered the mercy-seat, and wrought the ornaments of the pectoral to be worn by the high priest.

As Chaldea, therefore, was the first peopled region of the earth after the Flood, and as it appears from various accounts that the art of engraving upon bricks baked in the sun was there carried to a considerable degree of perfection at a very early period, it appears highly probable that the Chaldeans derived the rudiments of the art of sculpture immediately from their antediluvian ancestors.

The origin of idolatrous worship is generally thought to be derived from images first made to preserve the memory of the dead, and, in process of time, converted by the flatterers of great men into objects of adoration. This also affords presumptive evidence that the Chaldeans were the first who invented the art of hewing blocks of wood and stone into the figures of men and other animals; for the Chaldeans were unquestionably the first idolaters, and their early progress in sculpture is confirmed by the united testimonies of Berosus, Alexander, Polyhistor, Apollodorus, and Pliny.

Against this conclusion some plausible arguments have been urged on the authority of a theory established by a French writer, who maintains that in the year of the world 1949, about 300 years after the Deluge, the Scythians under Brouma, a descendant of Magog, extended their conquests over the greater part of Asia; and that Brouma was not only the civilizer of India, and the author of the Braminical doctrines, but also diffused the principles of the Scythian mythology over Egypt, Phœnicia, Greece, and the continent of Asia.

Leaving the consideration of this question, as too extensive for our present purpose, we shall endeavour to trace the progress of the art of sculpture through some other nations of antiquity, till we bring it to Greece, where it was carried to the highest perfection to which it has yet attained.

Phœnicia, in the immediate vicinity of Chaldea, must necessarily have very early acquired a knowledge of sculpture. The Phœnicians possessed both a character and situation highly favourable to the cultivation of this art. They beheld the most beautiful models in their own persons, and their industrious character qualified them to attain perfection in every art for which they had a taste. But as their situation raised a spirit of commerce, it is at all times questionable whether commerce induced them to cultivate the arts. Their temples shone with statues and columns of gold, and a profusion of emeralds were every where scattered; but the beauties of art do not consist in finery or ostentation of wealth. The greatest works of the Phœnicians have been unfortunately destroyed; many Carthaginian models indeed are still preserved, ten of which were deposited in the cabinet of the grand duke of Florence. But though the Carthaginians were a colony of Phœnicians, we should probably deduce from their works a very unfair estimate of the merit of their ancestors.

Very high pretensions to antiquity of every kind are made by the Persians; but we do not find that they ever made any distinguished figure in either of the arts of sculpture or painting. They were indeed sensible to the charms of beauty, but they did not study to imitate them. Their dress, which consisted of long flowing robes, concealing the whole person, prevented them from attending to the beauties of form. Their religion too, which taught them to worship the divinity in the emblem of fire, and that it was impious to represent him under a human form, seemed almost to prohibit the exercise of this art, by taking away the strongest incentives to art during the reign of superstition; and as it was not customary among them to raise statues to great men, it was impossible that statuary could flourish in Persia

The Persians, however, represented in their bas-reliefs many symbolical expressions of the powers of the Divinity, as well as of their religious ceremonies or heroic achievements. The bas-reliefs on the palace of Persepolis and the tombs of the Persian sovereigns, are arranged in horizontal and perpendicular lines, answering the double purpose of description and architectural decoration. The style of drawing in these bas-reliefs resembles that of later hieroglyphics, except in the dresses of the figures, which are different from those either of the Egyptians or Hindoos. The Persians are represented with long beards and ringlets, caps, full tunics, with regular folds and large sleeves. The Medes, in the same ruins of Persepolis, have close tunics. The drapery in these bas-reliefs is superior to that of the Egyptians, as bearing a greater resemblance to nature.

In Hindostan and Egypt the art of sculpture has been exercised in a similar manner in the shaping or adorning large rude masses of the hardest materials, and the works of these two nations may not improperly be considered together. The reader will find some accounts of their sculpture under the article ANTIQUITIES.

In India, bas-reliefs have been found in great numbers in the caves of Ellora and Elephantis: the subjects are religious. The drawing of the figures bears a strong resemblance to the Egyptian style, but they are less correct in their forms, the heads being generally very large, and the limbs disproportioned to the bodies. It may be questioned, from the greater simplicity of execution, whether the Egyptian hieroglyphics are not also more antient than the Hindoo; the ground in the former being level with the highest relievo, and in the latter cut down to the lowest outline of the figure.

The character and style of design among the Egyptians have been more fully noticed by writers, because the first progress of the art among that people is conceived to elucidate that of most other antient nations.

In the Egyptian idols, composed of parts of different animals, each part appears to have been distinctively studied from nature. In the human figure, the body and limbs were represented by general forms: the face, as being the most interesting part, was more minutely expressed. The form of a face was a rounded egg; the lines of the eye-brows and lids were simple curves, inclining upwards from the nose; and the bottom of the nose and the line of the mouth were also in a similar direction. The eyes were full, nearly on a level with the forehead and cheeks, and the lines of the eye-brows, lids, and borders of the lips, marked with precision. The chin appears small and bony, the neck round, the shoulders high and broad, and the muscles of the breast are almost the only ones that are distinguished in the whole body. The loins are narrow, the limbs in general round and slender, the joints slightly indicated, the hands and feet flattish, and the fingers and toes rounded without any appearance of joints, and nearly of the same length. This, with the allowance of some national peculiarities of form, may serve for the description of early sculpture in general among the antients.

The quadrupeds on Egyptian monuments are represented in profile, and in the simplest attitudes. The Egyptians excelled more in these than in the human figure; but the anatomy of these also is insufficient and incorrect. The lion and the sphinx are particularly to be noticed in their works.

The larger Egyptian hieroglyphics (whether engraven on the surface of their architecture, or on the forms of animals), in which the figure is cut or sunk, in such a manner that the surface of the ground is level with its highest projection, may be considered as a species of bas-relief, more simple, and consequently more antient, than any other. The greater part of their temples, and other public edifices, were covered with hieroglyphics, or sacred figure-writing, in this kind of bas-relief; the largest of which formed regular ornaments in the friezes, centres over the doors, and other architectural parts.

Besides the hieroglyphics, the Egyptians worked in bas-relief, with the ground levelled to the lowest part of the figures. In these they represented the great actions of their heroes, as may be seen in the palace of Karnac, engraved by Denon, and in those described in the Bird's Well, of which there is a specimen in the hall of the British Museum.

Winckelmann thought he discovered two different styles of Egyptian sculpture, which prevailed at different periods. The first of these ends with the conquest of Egypt by Cambyses. The second begins at that time, and extends beyond the reign of Alexander the Great. In the first style, the lines are straight, or projecting very little; the position is stiff and unnatural. In sitting figures, the legs are parallel, the feet squeezed together, and the arms fixed to the sides; but in the figures of women, the left arm is folded across the breast. The forms of the head and body are such as have been already described. The statues of men are naked, excepting only that they have a short apron, and a few folds of drapery surrounding their waist. The vestments of women are only distinguishable by the border which rises a little above the surface of the statue. In this age it is evident the Egyptians knew little of drapery.

Of the second style of sculpture practised among the Egyptians, Winckelmann found specimens in the two figures of basaltes in the capitol, and in another figure in the Villa Albani, the head of which has been restored. The two first of these, he remarks, bear visible traces of the former style, which appear especially in the form of the mouth and shortness of the chin. The hands possess more elegance; and the feet are placed at a greater distance from one another than was customary in more antient times. In the first and third figures the arms hang down close to the sides. In the second they hang more freely. Winckelmann suspects that these three statues were made after the conquest of Egypt by the Greeks. They are clothed with a tunic, a robe, and a mantle. The tunic, which is pleated in numerous folds, descends from the neck to the ground. The robe in the first and third statues appears to be every where close to the body, and is only perceptible by some little folds. It is tied under the breast, and covered by the mantle, the two buttons of which are placed under the epaulet.

The Antinous of the capitol is composed of two pieces, which are joined under the haunches; but as all the Egyptian statues which now remain have been hewn out of one block, we must believe that Diodorus, in saying the stone was divided, and each half finished by a separate artisan, spoke only of a Colossus. The same author informs us that the Egyptians divided the human body into 24¼ parts; but it is to be regretted that he has not given a more minute detail of that division.

The Egyptian statues were not only formed by the chisel; they were also polished with great care. Even those on the summit of an obelisk, which could only be viewed at a distance, were finished with as much labour as if they had admitted a close inspection. As they are generally executed in granite or basaltes, stones of a very hard texture, it is impossible not to admire the indefatigable patience of the artists.

The eyes were often of different materials from the rest of the statue; sometimes they were composed of precious stones or metal. We are assured that the valuable diamond of the empress of Russia, the largest and most beautiful hitherto known, formed one of the eyes of the famous statue of Scheringham in the temple of Brama.

After the Egyptian works of art, the most antient are those of the Etrurians or antient Tuscans, who, in the opinion of the same learned writer Winckelmann, made advances in sculpture at an earlier period than the Greeks. The art is said to have been introduced among them before the siege of Troy, by Dedalus; who, in order to escape the resentment of Minos, king of Crete, took refuge in Sicily, from whence he passed into Italy, where he left many monuments of his art. Pausanias and Diodorus Siculus inform us, that some works ascribed to him were to be seen when they wrote, and that these possessed that character of majesty by which the Etrurian sculpture was afterwards distinguished.

A character strongly marked forms the chief feature of those productions of Etruria which have descended to us. Their style was indeed harsh and overcharged; for it is not to be supposed that a people of such rude manners as the Etrurians could communicate to their works that refinement and beauty which the elegance of Grecian manners inspired. On the other hand, there are many of the Tuscan statues which bear so close a resemblance to those of Greece, that antiquarians have thought it probable that they were conveyed from that country or Magna Grecia into Etruria, about the time of the Roman conquest, when Italy was adorned with the spoils of Greece.

Among the monuments of Etrurian art, two different styles have also been observed. In the first the lines are straight, the attitude stiff, and the shape of the head without beauty. The general form of the figure is likewise too slender: the head is oval, the chin peaked, the eyes flat, and looking obliquely.

All these are evidently the defects of an art in a state of infancy, and some of them are equally conspicuous in the early statues of all nations. The style of the Etrurian sculpture is so similar to that of the Egyptians, that one is almost induced to suppose that there had once been a communication between these two nations; but the introduction of this style by Dedalus is generally credited.

Winckelmann supposes that the second epoch of the art commenced in Etruria about the time at which it had reached its greatest perfection in Greece, in the age of Phidias; but this conjecture is not supported by any proofs. To describe the second style of sculpture among the Etrurians, is almost the same as to describe the style of the modern restorers of the art in Tuscany. The joints are strongly marked, the muscles raised, the bones distinguishable, but the whole appearance is harsh, particularly in the representation of ordinary life. The statues of the gods are designed with more delicacy. In forming them the artists were anxious to show that they could exercise their power without that violent distension of the muscles which they conceived necessary in the exertions of beings merely human; but in general their attitudes are unnatural, and the actions strained. If a statue, for instance, holds any thing with its fore fingers, the rest are stretched out in a stiff position.

Greece. The earliest examples of Grecian sculpture remind us still more of the Egyptian, in the principles of design, than those of any other nation. The face of the human figure has the same kind of oval, the features are described by the same curves, the eye full, and the body and limbs represented nearly in the same general forms. The works of the early Greeks may, however, be justly said to be equal to the Egyptians in the proportions of their figures, and superior in the drawing of the body and limbs.

It is probable that sculpture preceded the use of letters in Greece, as in other nations; but the small bronze figures with inscriptions on them in Cadmean letters, are such weak and barbarous resemblances of the human form, that it is needless to trace its origin in any more remote period.

The Grecians began very early to study the proportions of the human form. Vitruvius informs us that "as the height of the human figure was six times the length of the foot, that was made the rule of proportion for the Doric column." Their knowledge, therefore, in this part of art, was antecedent to their architectural proportions.

Whether Greece received the principles of the arts from Egypt and Phœnicia, or, as they asserted, were the original inventors of them, it is certain that the native genius of the Grecians, combined with other peculiarly favourable circumstances, very soon raised sculpture from a state of barbarism.

In the earliest æra of sculpture in Greece, schools of design were established in the island of Ægina, at Corinth, and at Sicyon. This last city was styled the mother of the arts, as Diapænus and Scillides, and their disciples also, had flourished there; and after seven generations, Aristocles, the brother of Canacus, likewise a sculptor of eminence, presided over the same establishment with undiminished fame. The school of Ægina traced its origin to Dedalus, of fabulous renown: and his cotemporary Smilis made two statues of Juno; one for her temple at Samos, and the other for that at Argos.

From these auspicious dawnings of the art of sculpture, three distinct schools arose, one of which was peculiar to Ionia; the others were in Greece, at Athens, and at Sicyon, each of them shining with nearly equal splendour for several ages.

At the head of the first Grecian artists, stands Myron, whose statues in bronze attracted universal admiration. A Discobulus made by Myron, is particularly noticed by Quinctilian.

Phidias, whose name is better known in the present day than that of any other sculptor, was the disciple of Eladas and Ageladas, the probable cotemporaries of Myron, and who flourished in the sixteenth olympiad. We collect from Quinctilian, that he excelled in imparting a celestial dignity to his figures of the deities, two of which are celebrated in this respect, the Minerva at Athens, and Jupiter Olympius at Elis. Many of his most beautiful works were in ivory, frequently less than the natural size. He cast likewise in bronze.

In the same age lived Polycletus, whose works were distinguished by exquisite grace and most correct finishing: the latter quality was the effect of his singular diligence. To the human figure he is said to have given more than human beauty, but he failed in expressing the majestic character of the gods.

The works of Egesias were of a sublime style, but hard manner.

Of the school of Phidias, the most distinguished sculptors were Alcamenes of Athens, and Agoracritus of the island of Paros. Their rival skill was exerted in finishing a statue of Venus, and the palm was adjudged by the Athenians to their own citizen.

Polycletus of Sicyon was the competitor with Phidias in an undertaking of more grandeur and consequence than his general works. He was employed by the inhabitants of Argos to make a colossal statue of Juno, composed of gold and ivory, in order to emulate, rather than to imitate, the Olympic Jupiter of Phidias. Two figures in bronze by Polycletus representing the canephoræ or nymphs bearing in baskets the symbols of Ceres to a sacrifice, were taken from the Thespians by Verres, and brought to Rome. They were esteemed beyond any bronze figures existing at that time. Such was the skill of this eminent master, that he completed so perfect a human figure that it served as a model to his successors, and was considered by Lysippus as the acme of his art.

While Phidias in gold and ivory, and Polycletus in bronze, engrossed to themselves every excellence, Scopas acquired a scarcely inferior celebrity for his statues in marble. The groupe of Niobe and her children is attributed by Pliny to Scopas or Praxiteles, he does not decide which.

The last sculptor (of whose works we have any knowledge) coeval with Phidias, was Ctesilaus, who, jointly with him and Polycletus, finished one of the three Amazons designed to decorate the temple of Diana at Ephesus, and the statue of Pericles, commended by Pliny, who allows to Ctesilaus the felicity of giving to his heroes a still more noble air than they possessed.

The names of Policles, Cephisodorus, Leochares, and Hippodotus, are preserved from oblivion by Pliny, but none of their works remain. Leochares was one of the four artists employed in adorning the mausoleum built by the celebrated Artemisia, queen of Caria, to the memory of her husband.

Menestratus, Socrates, Philiscus, Lysias, Mirmecides, and many others, are also spoken of with praise by various writers; but we have unfortunately no other remaining testimonies of their merits.

Of the first style of the Grecian sculptors, so remarkable for simplicity and grandeur, the æra was circumscribed to the limits of fifty years, during which period the art had arrived at its meridian of sublimity. The succeeding age introduces Praxiteles, who may be called the father of the second manner, and whose works were discriminated by their flowing outline and delicate finishing. The elevation of Thebes by Epaminondas above the other states of Greece, produced a complete change in her whole system; but as soon as the Athenians recovered their former splendour, the arts, which had ever accompanied the vicissitudes of her fortunes, revived with unabated splendour. The works of Praxiteles are celebrated by historians and poets. His Venus of Gnidus in marble, attracted then no less admiration than the Medicean Venus has done in the modern world; and his Apollo in bronze, called (from the lizard in the trunk of the tree against which he leans) Sauroctonos, is still among the most admired productions of sculpture.

Not long after Praxiteles had signalized himself in statuary, and particularly in bronze, Lysippus appeared, whose great merit consisted in following nature more scrupulously than any of his immediate predecessors. If, as Pliny reports, his works were so numerous as to amount to not less than fifteen hundred, we have the more cause to regret that they were all of bronze, and are irretrievably destroyed. He flourished under the reign of Alexander.

To Agesander, Polydorus, and Athenodorus, is ascribed (by Pliny) the celebrated group of the Laocoon and his sons, and conjecture has been frequently busied in endeavouring to discriminate the particular portion of each artist; but conjecture only has hitherto been produced. Abbé Winckelmann conjectures that Agesander was the father of the other two artists, and that he himself finished the statue of Laocoon, leaving the children to be wrought by his sons.—"Credat Judæus apella." No authentic document remains by which the time in which these artists flourished can be ascertained.

Neither do we know the precise date of Apollonius and Tauriscus, the authors of a no less celebrated group representing Dirce tied to the horns of a bull (in order to be precipitated into the sea) by Zethus and Amphion, the sons of Antiopa. This work is generally supposed to have been cotemporary with the rival group of Laocoon. In an inscription on it, now obliterated, was traced the name of another artist, Menecrates. This vast mass of sculpture is said to have been formed out of a single block, in the island of Rhodes. It has suffered greatly in the course of time.

Greece, after the death of Alexander the Great, lapsing into a state of dependance little better than slavery, the arts were for a time wholly neglected; and might have been nearly annihilated, had they not found refuge in Asia, under the patronage of the Seleucidæ. Men of talents also in every profession, sought at that time in Egypt the encouragement afforded them by Ptolemy Soter, who exhibited a munificence worthy of Alexander, his predecessor in that kingdom. But when the Roman consul, Quintus Flaminius, proclaimed, at Corinth, universal liberty to Greece (about a hundred and ninety-four years before Christ), the public tranquillity, consequent on that event, renewed the spirit of the arts, and introduced another of their most memorable æras.

Callistratus, Athenæus, and Policles, were immediately at this period the most renowned masters of sculpture. Policles distinguished himself by the statue of the Hermaphrodite, so long admired in the Borghese Villa at Rome.

To Apollonius the Athenian, at the same period, is attributed the wonderful Torso of the Hercules, preferred by the judgment of Michael Angelo beyond the most perfect statues of Rome.

Causes of the excellence of sculpture among the Greeks.

The great superiority of the Greeks in the art of sculpture, may be ascribed to a variety of causes. Their love of beauty was so great, that the Lacedemonian women kept in their chambers the statues of Nereus, of Narcissus, of Hyacinthus, and of Castor and Pollux; hoping that by often contemplating them, they might have beautiful children.

The noble and virtuous freedom of the Grecian manners likewise contributed in a more peculiar degree to the cultivation of the fine arts. There were no laws, as among the Egyptians, to check their progress. The artist had the best opportunities to study them in the public places, where the youth, who needed no other veil than chastity and purity of manners, performed their various exercises quite naked.

The strongest motives were also held forth for the cultivation of sculpture, for a statue was the highest honour which public merit could attain. It was an honour ambitiously sought, and granted only to those who had distinguished themselves in the eyes of their fellow-citizens. As statues were often raised to those who excelled in the public exercises, the most eminent men of Greece, in their youth, sought renown in the gymnasia. Here Chrysippus and Cleanthes distinguished themselves before they were known as philosophers. Plato appeared as a wrestler both at the Isthmian and Pythian games; and Pythagoras carried off the prize at Elis. The number of statues erected on different occasions was immense; of course, the number of artists must have been great, their emulation ardent, and their progress rapid. Moreover, at these public games, the artists could not fail of seeing the most excellent models; for those who surpassed in running, boxing, and wrestling, must not only, in general, have been well formed, but would exhibit different kinds of beauty.

The high estimation in which sculptors were held, was also very favourable to their art. An artist could be a legislator, a commander of armies, and might hope to have his statue placed at the side of those of Miltiades and Themistocles, or those of the gods themselves. The productions of art were estimated and rewarded by the general assembly of Greece; and the sculptor who had executed his work with ability, was confident of obtaining immortality.

Character of Grecian sculpture.

Winckelmann has assigned four different styles to this art among the Greeks. The antient style, which continued until the time of Phidias; the grand style, formed by that celebrated statuary; the beautiful, introduced by Praxiteles, Apelles, and Lysippus; and the imitative style practised by those artists who copied the works of the antient masters.

The most authentic monuments of the antient style have been already described. The statues formed in this style were neither distinguished by beauty of shape, nor by proportion, but bore a close resemblance to those of the Egyptians and Etrurians. The eyes were long and flat; the section of the mouth not horizontal; the chin was pointed; the curls of the hair were ranged in little rings, and it was impossible by inspecting the head to distinguish the sex.

The character of the antient style was energetic, but harsh; it was animated, but without gracefulness; and the violence of the expression deprived the whole figure of beauty.

The grand style was brought to perfection by Phidias, Polycletus, Scopas, Alcamanes, Myron, and other illustrious artists. It is probable, from some passages of antient writers, that in this style were preserved some characters of the antient manner, such as the straight lines, the squares, and angles. The antient masters, such as Polycletus, being the legislators of proportion, says Winckelmann, and of consequence thinking they had a right to distribute the measures and dimensions of the parts of the human body, have undoubtedly sacrificed some degree of the form of beauty to a grandeur which is harsh, in comparison of the flowing lines and graceful forms of their successors. The most considerable monuments of the grand style, are the statues of Niobe and her daughters; and a figure of Pallas, to be seen in Villa Albani; which, however, must not be confounded with another statue, modelled according to the first style, and also found in the same place; the head of which possesses all the characters of dignified beauty, at the same time exhibiting the rigidness of the antient style. The figures of Niobe and her daughters have not, in the opinion of Winckelmann, that austerity of appearance which marks the age of the last-mentioned statue of Pallas. They are particularly characterised by grandness and simplicity.

The third style was the graceful or beautiful. Lysippus was, perhaps, the artist who introduced this style. Being more conversant than his predecessors with the flowing and beautiful lines of nature, he avoided the square forms which the masters of the second style had too frequently admitted. He was of opinion that the art ought rather to please than to astonish, and that the aim of the artist should be to raise admiration by giving delight. The artists who cultivated this style, did not, however, neglect to study the sublime works of their predecessors. They knew that grace is consistent with the most dignified beauty; and that while it possesses charms which must ever please, those charms are enhanced by dignity. Grace is inspired into all the movements and attitudes of their statues. It appears in the delicate turn of the hair, and even in the adjusting of the drapery.

The last, or imitative style, is of an inferior degree of excellence to that which has just been mentioned. The great reputation of Praxiteles and Apelles raised an ardent emulation in their successors, who, despairing to surpass such illustrious masters, were satisfied with imitating their works.

Every species of beauty of form appears to have been well known to the antients; and great as the ravages of time have been amongst the works of art, specimens are still preserved in which can be distinguished dignified beauty, attractive beauty, and a beauty peculiar to tender age. A specimen of dignified beauty may be seen in the statue of one of the muses in the palace Barberini at Rome, and in the garden of the pope. On the Quirinal is a statue of another muse, which affords a fine instance of attractive beauty. Winckelmann says that the most excellent model of infant beauty which antiquity has transmitted to us, is a satyr of a year old, which is preserved, though a little mutilated, in the Villa Albani.

Nor were the sculptors who represented with such success the most perfect beauty of the human form, regardless of the drapery of their statues. They clothed their figures in the most proper stuff, which they wrought into that shape which was best calculated to give effect to their design.

The vestments of women in Greece generally consisted of linen cloth, or some other light stuff, and in latter times of silk, and sometimes of woollen cloth. They had also garments embroidered with gold. In the works of sculpture, as well as in those of painting, one may distinguish the linen by its transparency and small folds. The other light stuffs which were worn by the women, were generally of cotton, sometimes striped, and sometimes embellished with a profusion of flowers. Silk was also employed; but whether it was known in Greece before the time of the Roman emperors, cannot easily be determined.

The vestments of the Greeks, which deserve particular attention, are the tunic, the robe, and the mantle.

The tunic was that part of the dress which was next to the body. It may be seen in the Flora Farnese, and in the statues of the Amazons in the capitol. The youngest of the daughters of Niobe, who throws herself into her mother's arms, is clothed only with a tunic. It was of linen, or some other light stuff, without sleeves, fixed to the shoulders by a button, so as to cover the whole breast. None but the tunics of the goddess Ceres, and of comedians, have long straight sleeves.

The robes of women commonly consisted of two long pieces of woollen cloth, without any particular form, attached to the shoulders by a great many buttons, and sometimes by a clasp. They had straight sleeves, which came down to the wrists. The young girls, as well as the women, fastened their robe to their side by a cincture, fastened on the side in a knot, as it is still done in many parts of Greece; a knot of ribbons sometimes resembling a rose in shape, which has been particularly remarked in the two beautiful daughters of Niobe. In the younger of these, the cincture is seen passing over the shoulders.

and the back. Venus has two cinctures, the one passing over the shoulder, and the other surrounding the waist. The latter is the cestus so celebrated by the poets.

The mantle was called peplon by the Greeks, which signifies properly the mantle of Pallas. The name was afterwards applied to the mantles of the other gods, as well as to those of men. This part of the dress was not square, as some have imagined, but of a roundish form. The antients, indeed, speak in general of square mantles, but they received this shape from four tassels which were affixed to them: two of these were visible, and two were concealed under the mantle. The mantle was brought under the right arm, and over the left shoulder: sometimes it was attached to the shoulder by two buttons, as may be seen in the beautiful statue of Leucothoe at Villa Albani.

With respect to the head, women generally wore no covering but their hair; when they wished to cover their head, they used the corner of their mantle. Sometimes we meet with veils of a fine transparent texture. Old women wore a kind of bonnet upon their head, an example of which may be seen in a statue in the capitol, called the Præsica; but Winckelmann thinks it is a statue of Hecuba.

The covering of the feet consisted of shoes or sandals. The sandals were generally an inch thick, and composed of more than one sole of cork. Those of Pallas in Villa Albani have two soles, and other statues had no less than five.

But in no part of art are the Grecian sculptors more eminently excellent than in the general characteristic expression which they gave to their figures.

The most elevated species of tranquillity and repose was studied in their figures of the gods. The father of the gods, and even inferior divinities, are represented without emotion or resentment. But Jupiter is not always exhibited in this tranquil state. In a bas-relief belonging to the marquis Rondini, he appears seated with a melancholy aspect. The Apollo, once called of the Belvedere, in the Vatican, represents the god in the act of discharging from his bow the mortal shaft against the serpent Python.

To express the action of a hero, the Grecian sculptors delineated the countenance of a noble virtuous character repressing his groans, and allowing no expression of pain to appear.

Philoctetes is introduced by the poets shedding tears, uttering complaints, and rending the air with his groans and cries; but the artist exhibits him silent, and bearing his pains with dignity; in the same manner as the Ajax of the celebrated painter Timomachus was not drawn in the act of destroying the sheep which he took for the Grecian chiefs, but in the moments of reflection which succeeded that frenzy.

Illustrious men, and those invested with offices of dignity, are represented with a noble assurance and firm aspect. The statues of the Roman emperors (executed by Greek artists) resemble those of heroes, and are far removed from every species of flattery, in the gesture, in the attitude, and action. They never appear with haughty looks, or with the splendour of royalty. None but captives are ever represented as offering any thing to them with bended knee.

The Greek works of ivory and silver were not always of a small size. The colossal Minerva of Phidias, which was composed of these materials was twenty-six cubits high. It is indeed scarcely possible to believe that statues of such a size could entirely consist of gold and ivory. The quantity of ivory necessary to a colossal statue is beyond conception. M. de Pauw calculates, that the statue of Jupiter Olympus, which was 54 feet high, would consume the teeth of 300 elephants.

The Greeks generally hewed their marble statues out of one block, though they afterwards worked the heads separately, and sometimes the arms. The heads of the famous group of Niobe and her daughters appear to have been adapted to their bodies after being separately finished. It is proved by a large figure representing a river, which is preserved in Villa Albani, that the antients first hewed their statues roughly, before they attempted to finish any part. When the statue had received its perfect figure, they next proceeded to polish it with pumice-stone, and again carefully retouched every part with the chisel.

The antients, when they employed porphyry, usually made the head and extremities of marble. It is true, that at Venice there are four figures entirely composed of porphyry; but these are the productions of the Greeks of the middle age. They also made statues of basaltes and alabaster.

The antients, as well as the moderns, made works in plaister; but no specimens remain, except some figures in bas-relief, of which the most beautiful were found at Baiæ, near Naples.

We have been thus minute in our account of the Grecian sculpture, because it is the opinion of the ablest critics, that modern artists have been more or less eminent, as they have studied with the greater or less attention the models left us by that ingenious people. Winckelmann goes so far as to contend, that the most finished works of the Grecian masters ought to be studied in preference even to the works of nature. The reason assigned by the abbé for his opinion is, that the fairest lines of beauty are more easily discovered, and make a more striking and powerful impression, by their reunion in these sublime copies, than when they are scattered far and wide in the original of nature. Allowing, therefore, the study of nature the high degree of merit it so justly claims, it must nevertheless be granted, that it leads to true beauty by a much more tedious, laborious, and difficult path, than the study of the antique, which presents immediately to the artist's view the object of his researches, and combines in a clear and strong point of light the various rays of beauty that are dispersed through the wide domain of nature. But this reasoning is too paradoxical to be admitted, without great allowances for the peculiar creed of the writer.

Decline of Greek sculpture.

When the restless genius of the Grecians, and the aggressive spirit of the Romans, conspired to the second thraldom of the Greek states, and L. Mummius was directed to lay siege to Corinth, the capture of a city so famed as the repository of all that was most perfect in the arts, provoked the avarice of the conqueror; who, by transporting many of the most superb works of taste to Rome, to grace his triumph, excited in his fellow-citizens so insatiable an ardour of possessing treasures of the same kind, as totally transferred the seat of the arts from Athens to the growing metropolis of the world.

Sicyon, at the same period, had been ravaged by M. Scaurus, and Sparta by Muræna and Varro: and Greece began thus to be exhausted of all it once boasted in art. Nor was the fate of the arts in Egypt more auspicious; whence, after the defeat of the Seleucidæ, they took refuge in the court of Attalus; but their security was there of short duration. On the death of Attalus, his territory devolved to the Romans; and the treasures of sculpture which adorned his palace, were also transferred to Rome.

Rome. After taking a view of the extinction of the arts in Greece, we may find some satisfaction in directing our minds to the introduction of them at Rome, and to the liberal encouragement which men of talents experienced even from their haughty and rapacious conquerors.

Pasiteles, a name which has been confounded with Praxiteles, was a native of Calabria; and cast in silver a statue of Roscius, the celebrated actor, as an infant lying in a cradle, and entwined by a serpent, a situation of danger from which his nurse is said to have preserved him. Nearly about the same time, Archesilaus and Evander were in great request at Rome. Archesilaus was patronized by the profuse and wealthy Lucullus; and both these artists had gained celebrity by their works in chalk, modelled probably from the finest antiques, as well as being specimens of their own invention. A Venus, made for Julius Cæsar, and the restoration of a head of Diana for a statue, the original work of Timotheus, the contemporary of Scopas, by the command of Augustus, are noticed by Pliny as their work, and ascertain their æra, and their fame. Horace alludes to the superior style of Evander in bas-reliefs.

Among the monuments of sculpture made at Rome, in these last days of her republic, and certainly by Grecian artists, are the two statues of the Thracian kings, as prisoners at a triumph, in grey marble. These were kings of the Scordisci, a rude people, who were defeated by M. Licinius Lucullus. Exasperated by their repeated perfidy, he commanded their hands to be cut off, a circumstance of cruelty represented in the marble, which now remains in the museum of the capitol.

The statue of Pompey (now in the hall of the Spada palace, but originally standing in the curia or basilica of Pompey), at the base of which Cæsar fell, affords a singular proof of a deviation from the known custom of the Romans, who represented their living heroes in armour. But the great triumvir is sculptured as a deified hero, naked, and of colossal proportions.

Abbate Winckelmann, with great ingenuity, asserts the statue denominated Cincinnatus at Versailles, and another called Marcus Agrippa at Venice, to have been of an earlier æra than that of those celebrated Romans; and shews, with sufficient evidence, that the style in which they are executed is of a prior date.

We must now consider the arts as transplanted to Rome, although still professed, almost exclusively, by Greek sculptors. Julius Cæsar, who, while in a private station, had made an extensive collection of intaglios, and small figures in ivory and bronze; and who, when dictator, dedicated them as a public benefaction in the temple of Venus Genitrix; may be said to have left the love of the arts as an inheritance to the Romans.

Augustus, after he assumed the imperial government, dispatched Memmius Regulus to collect from every city of Greece the statues yet remaining in them. His orders were so well observed, that the finest pieces of sculpture were brought to Rome, with a profusion by which his palaces were crowded; and many were distributed in his numerous villas. The Olympian Jupiter, of Phidias, composed of gold and ivory, was almost the only statue that escaped; the artists of Greece asserting, that from the state of its materials, it would not bear removal.

Augustus encouraged also the prevailing mode of representing in statuary the most distinguished characters of the age, and placed many of their statues in public situations of eminence.

Succeeding emperors followed the example of Augustus. We are informed by Pausanias, that from the temple of Delphos only, five statues were transported to Rome by Nero, who also emplyed Zenodorus to cast a colossal statue of him in bronze 110 feet high.

Nero, however, indulged the perverseness of his taste in gilding, and otherwise disfiguring, many of these exquisite works.

The triumphal arch built by Titus, and the frieze in the temple of Minerva, built by Domitian, give a very favourable idea of the arts under those emperors.

In the sculpture of triumphal bas-reliefs and trophies, the artists were particularly eminent. The architectural plans adopted by Trajan were of such magnitude, that men of every kind of talents were invited to signalize themselves under his munificent patronage. His bridge over the Danube, his triumphal arch at Ancona, his forum including the column which now bears his name, appear to have given employment to all the powers of human skill.

Under the auspices of Hadrian, the successor of Trajan, the arts maintained a progressive degree of excellence. He was eminently accomplished, not only as an admirer, but was himself an artist. Every province in Greece enjoyed his munificence; and the temple of Jupiter at Athens, which he restored, and that of Cyzicum, on the shores of Propontis, which he built, were stupendous monuments of imperial splendour. Having for eighteen years been engaged in visiting the most distant parts of the Roman empire, he resolved to construct his villa at Tivoli; in which, not only exact models of the most celebrated buildings he had seen, should be erected, but that they should be furnished with originals, or the finest copies, of the most admirable statues. His correct judgment in all works of art contributed more to the absolute superiority of this collection, than the mere power of expending unlimited treasures to procure it.

It was by Hadrian that the fashion of having portraits in statuary was so generally extended amongst the noble and opulent citizens of Rome. In his own villa at Tivoli were placed, by his command, the statues and busts not only of all his living, but of his deceased, friends. Of his favourite Antinous, in various characters, there are infinite repetitions. That most valued was found on the Esquiline hill, and was placed by Leo X. in the Vatican: but it has lately been described as Mercury, by the abate Visconti. Another was found about 1770, in the Thermæ Maritimæ of Hadrian, near Ostia. It represents Antinous in the mythological character of Abundance, and is now in the collection of the Hon. J. Smith Barry, at Beaumont, in Cheshire.

Some curiosity will be excited to enquire the names of those artists who were so constantly employed, and so amply patronised, by Hadrian. Those only of Aristæus, Papias, and Zeno, occur on the plinths of fragments discovered amongst the Tiburtine ruins.

We are now advancing rapidly to the decline of sculpture among the Romans. Of the two Antonines, M. Aurelius appears to have been the greater friend of the arts. His equestrian statue in bronze in the area of the capitol, still defies the competition of the modern artists. This last epoch includes the reigns of Trajan, Hadrian, and the Antonines, and terminates within that of Commodus. It was most remarkable for the character and high-finishing of heads intended as portraits, particularly of the imperial busts, as of M. Aurelius, Commodus when young, and of Lucius Verus.

A statue, said to be of that degenerate monster Commodus, in the character of a young Hercules, is in the Belvedere; but the superior style of the hair is a decisive proof, according to the judicious Winckelmann, that it is a genuine Hercules of much higher antiquity.

But a far inferior state of sculpture, in which none of its pristine elegance could be traced, is apparent in the bas-reliefs of two triumphal arches, erected at Rome in the reign of Septimius Severus. The arts, however, cannot be supposed to have declined so suddenly from a scarcity of those persons who professed them; for many portraits in marble, both of this emperor and his favourite minister Plautianus, afford a convincing proof, that the sculptors were many, yet that the art was in decay.

The several authors who have pursued this inquiry with the most ample and critical investigation, are undecided in fixing the exact period of the extinction of the arts at Rome. Some allow no proofs of their existence later than the Gordians; and by others they are extended to the reign of Licinius Gallienus, in the 268th year of Christianity. Why the profession of the arts should, in a great measure, cease, several causes have been given; but the principal and most obvious one is, that when Constantine determined to establish at Byzantium another capital of the Roman world, he pillaged the old metropolis of its most valuable statuary, to embellish a rival city. Those cities of Greece also which were contiguous, supplied, of course, an easy prey. Implicit credit perhaps is not to be given to an author of such questionable veracity as Cedrenus; but from him we learn, that Constantine had collected the Olympic Jupiter of Phidias, the Gnidian Venus of Praxiteles, and a colossal Juno, in bronze, from her temple at Samos; not to detail more of his catalogue. These, according to Nicætas, were broken in pieces, or melted down, at the surrender of the Eastern empire, and its metropolis, in 1204, to the French and Venetians. The four bronze horses in the Duomo of St. Mark at Venice, were preserved from destruction, and transported in triumph.

From the reigns of the first Byzantine emperors, to the immediate successors of Theodosius, we may perceive a ray of their former genius still animating the Greek artists. The historical column of Arcadius rose in no very unequal emulation of those of Trajan and Antonine at Rome. But from many epigrams of the Anthologia, it is evident that able artists were to be found; and it may be candid to suppose, that such praise was not, in every instance, extravagant or unmerited. At the same time that Rome was laid waste by the Goths, the works in bronze by the artists at Constantinople were held in considerable estimation.

In the conclusion of his History of the Decline and Fall of the Roman Empire, the erudite Gibbon has given a perspicuous account of the causes to which the ruins of Rome may be ascribed.

During the fifteenth century, Petrarch and Poggius, the celebrated Florentine rhetorician and lawyer, very eloquently describe the dilapidation by which they were surrounded in their view of the imperial city, after many centuries of injury sustained from the Goths, the zeal of the primitive Christians, the civil wars of her own nobility, and the waste of materials, or the gradual decay of time.

Poggius asserts, that six perfect statues only remained, of all the former splendour of the mistress of the world. Four were extant in the baths of Constantine; the others were that now on the Monte-cavollo, and the equestrian statue of M. Aurelius. Of these, five were of marble; the sixth and last is of bronze.

Poggius was the first collector of antique statues; and from him the great Cosmo de Medici acquired a love of the arts, and learned to enrich his cabinet with their productions. His successors, with hereditary emulation, exerted every power of wealth and influence, to render that cabinet the envy of Europe.

An investigation of the remains of Roman grandeur, so long and sedulously pursued, was rewarded by frequent discoveries of the finest antique sculptures; and the artists of the modern schools established at the Florence, gave the first proofs of their ingenuity in restoring and adapting those precious fragments.

Many curious particulars relative to the discovery of antique statues in the sixteenth century, may be found in Ficoroni, in an account by Flaminius Vacca, printed at the end of Nardini's Roma Antica, and in Montfaucon. Several of these are also to be found in Dallaway's Anecdotes, from which many parts of this account of the arts have been selected.

Modern art of sculpture.

Of the sculptors of the modern school, the first who are deserving of notice are Niccolo Pilani, and his son Giovanni, whose works in bas-relief became the principal ornaments of the cathedrals which were built in Italy in their time. They were born at Pisa, and flourished in the middle of the 13th century. To their names is to be added that of Niccolo dell' Arca.

To these succeeded Donatello, born at Florence, in 1393, whom an Italian author calls the reviver of sculpture: and Lorenzo Ghiberti, celebrated for his admirable bas-reliefs in bronze on the gates of the Baptistery of St. John at Florence, of which Michael Angelo said, that they deserved to be the gates of Paradise. The compartments of these gates are filled with subjects taken from the Old Testament. The accompanying ornaments of fruits, flowers, &c. are of the most exquisite workmanship.

The list of succeeding sculptors, in Tuscany, is very numerous. Those of the greatest celebrity are Michael Angelo Buonaroti, no less eminent in sculpture than in painting; Baccio Bandinelli; Niccolo, called il Tribolo; Gulielmo della Porta; Jacopo Sansovino; Annibale Fontana; Benvenuto Cellini; Mont Orsoli; Giambologna, &c. &c.

To these is to be added the name of Propertia di Rossi distinguished as much by her misfortunes as her talents. Her history is singularly interesting, if the circumstances related of her are authentic.

Propertia di Rossi was born at Bologna, at the close of the fifteenth century. She was not only versed in sculpture, but had reached also no common excellence in music. Her first works were carvings in wood, and on peach-stones, eleven of which were in the museum of the marquis Grassi at Bologna, each representing on one side one of the apostles, and on the other several saints. In these minute attempts having gained universal applause, she then gave a public proof of her genius in a work of considerable importance, which she finished in marble, for the front of the cathedral of St. Petronius. A bust of count Guido Pepoli was likewise greatly admired. The rules of perspective and architecture were equally familiar to her. With all these talents, and a fame unrivalled by her sex, Propertia was most unfortunate. In early life she had been married without sympathy, and had fixed her affections on one whose heart was totally insensible. While her health was daily yielding to despair, she undertook the bas-relief, representing the story of Joseph and Potiphar's wife, which forms the principal subject of the work above-mentioned, belonging to the church of St. Petronius. It was at once a monument of her hopeless passion, and of her admirable skill.

The juvenile talents of Michael Angelo were displayed in the imitation, first of Donatello, and next of the antique; but he soon formed his own distinct style, consistent with the character of his native genius. This style was, like his painting, invariably grand. His anatomical knowledge was at all times conspicuous, and the display of it sometimes exceded the just bounds. His works in various cities of Italy are numerous. The principal ones are at Rome and Florence. In the former city, the monument of Julius II. in the church of St. Pietro in Vincoli, (which comprises the well-known statue of Moses) and the celebrated work of the Pieta, in a chapel in St. Peter's, are worthy of the highest admiration. At Florence, his greatest work is in the sacristy of St. Lorenzo, where he has placed the statues of the dukes Lorenzo and Giuliano Medici, together with four emblematic figures of Night, Day, Twilight, and Dawn.

The superior genius of this great artist established the school of sculpture in Florence; and his successors were, for a long period, little more than imitators of his style. But although they succeeded in giving to their figures an appearance of anatomical knowledge, they were far from equalling their great exemplar in his profound conception of the principles of art. They may of course all be considered as his inferiors in a line which he had marked out for them.

With the decline of the republic of Florence, the arts also sunk into decay, or took their flight to Rome, where Algardi became the author of a new style, by studying to unite the effects of painting with those of sculpture, and thus deserting the real intent of his art; which is to imitate the forms, not the appearances, of objects, the latter being the province of painting.

By these means sculpture assumed, under the hands of Algardi, a mannered air, which it has never since wholly lost.

One of the most extraordinary works of Algardi, is a large bas-relief, placed over an altar in St. Peter's church; in which he has represented St. Peter and St. Paul in the air, averting by their menaces the haughty Attila, who was advancing to the attack of Rome. The principal figures in this singular work are of the highest relievo; those which are supposed less in front are in mezzo-relievo; and in the others the degree of relief is proportionally diminished, until the most distant figures are only marked with a simple line. This was considered in his time as the mode of perfecting bas-relief; and Pope Innocent the Tenth rewarded the artist with a present of 30,000 Roman crowns.

To Algardi succeeded Lorenzo Bernini, born in 1598, who, pursuing the track which Algardi had begun, and distinguishing himself at an early age by extraordinary maturity of talents, consulted ever afterwards no other rules than the indulgence of his own fancy, and sought celebrity from the flights of caprice and extravagance. His first group was Apollo and Daphne, at the moment that the nymph begins to exhibit the change from her natural form to that of the laurel-tree. The figures are remarkably light and graceful, and the fame which this work acquired for its author was of the most excessive degree. His latter works at Rome were the celebrated chair of St. Peter's church, the monument of the popes Urban the Eighth and Alexander the Seventh, the equestrian statue of Constantine, and the fountain in the Piazza Navona.

The sculptors who followed were the imitators sometimes of one, and sometimes of the other, of these two masters.

At the same period flourished Francois du Quesnoy, called Fiammingo, unrivalled in the beautiful and tender forms of his infantine figures. In his statue of Saint Susanna, he proposed to imitate the simplicity of the antique; and succeeded (says Mengs) in imitating the superficial appearance, but not the essential maxims, of the antients.

Rusconi is the last sculptor worthy of particular notice, until the appearance of Antonio Canova, a Venetian, now living, and whose productions exhibit talents of a very extraordinary rank. Many accounts of his works are to be found in the relations of modern travellers.

Of a date very little later than the revival of art at Florence, is the commencement of its cultivation in France. While Michael Angelo was disclosing his wonderful powers at Rome, under the pontificate of Leo the Tenth, Jean Goujon attracted the admiration of Paris, in the reign of Francis the First, and continued to receive it in that of Henry the Second. His name is frequently placed in competition with the sculptors of the Italian school. "The works of Goujon (says a French writer) recal to our view the simple and sublime beauties of the antique." His figures were however more esteemed on the score of grace than of correctness. He excelled particularly in works of mezzo-relievo. The Fontaine des Saints Innocens, in the Rue St. Denis at Paris, is an instance of his merit in this kind; as is also the tribune, supported by colossal Caryatides, in the Salle des Cent Suisses at the Louvre.

Girardon, born in 1627, was at once (like the preceding artist) a sculptor and architect. His works were admired for the correctness of design, and beauty of composition; and he was said by his countrymen to have produced chefs-d'œuvres only. The magnificent mausoleum of cardinal Richelieu in the church of the Sorbonne, the equestrian statue of Louis the Fourteenth in the Place Vendome, and numerous statues and groups in the gardens of Versailles, are testimonials of his merit.

Cotemporary in age and fame with Girardon, was Puget, born at Marseilles, in 1622, and denominated by Louis the Fourteenth "the Inimitable." He studied from the age of 16 to 21, in Italy, where he distinguished himself equally for the quickness of his talents, and his extraordinary diffidence in them. Soon after his return to his own country, he was invited to Paris by M. Colbert, and executed many admirable works, particularly the groups of Milo, and of Andromeda rescued by Perseus, in the park of Versailles. His works are celebrated by the French for their elevated taste, correctness of drawing, nobleness of character, and in general the most happy fertility of genius. His artful disposition of drapery for the display of the form beneath it, is much admired. Puget's reputation was at its height when Bernini became eminent at Rome; and it is not more creditable to one than to the other of these sculptors, that when Louis the Fourteenth sent an invitation to Bernini to come to Paris, that artist replied, that the king of France had no occasion for his talents, while he had such a sculptor as Puget in his dominions.

The other countries on the continent having chiefly received the rudiments of art from the two already mentioned, have cultivated a similar taste in most of their works of sculpture. Many artists, however, have appeared worthy of high praises: and in modern days the names of Zauner in Vienna, Sergel in Stockholm, and Koslovski in Petersburgh, stand high in estimation.

It is now requisite to turn our attention to England; where, although the early period of the kingdom have left many memorials of the talents of our artists, the present school of sculpture is of a very recent date. From the time of the Reformation, the art of sculpture has been almost wholly in the hands of foreign artists. Cibber, Gibbons, Rysbrack, Scheemaker, Roubillac, and some others, were employed on all public occasions to the exclusion of native artists.

The principal works of Cibber are the statues on the front of Bedlam, those of several of our kings round the Royal Exchange, and others at Chatsworth and Cambridge. He was the father of the celebrated dramatic writer Colley Cibber.

Of Grinling Gibbons is a statue in bronze of James II. now in Scotland-yard, in the Roman costume. In minute ornaments, carved in wood, Gibbons has few equals. His works of that kind are frequent: some of the best are at lord Egrement's at Petworth, Windsor, and the duke of Norfolk's at Holm Lacey. In the chapel of Trinity-college, Oxford, are other striking proofs of his genius.

Rysbrack's first appearance in England was about the year 1720, when the statuaries of Paris, particularly Le Paûtre, Vancleve, Bouchardon, and Le Gros, enjoyed the first reputation, and had many scholars, whose invention was exhausted in the classical fopperies of the royal gardens. Wherever he acquired the elements of his art, he displayed talents of a masterly artist in England. His bronze equestrian statue of king William at Bristol, and his monument of bishop Hough in Worcester-cathedral, are counted among his superior works.

Some of the busts by his hand are, John Baliol, king of Scots, at Baliol college; Alfred, at the university, finished by Wilton; Gibbs, the architect, in the Radcliff library; Dr. R. Friend, archbishop Boulter, and probably the busts of George I. and II. at Christchurch.

Scheemakers has left many valuable works: his statue of Shakspeare, on the monument of our immortal bard, in Westminster-abbey, procured him the greatest celebrity.

Roubillac was a native of Lyons, a city which has given birth to several French sculptors; to Coysevox, N. Coustou, and l'Amoureux, the cotemporary of Roubillac, and with some probability his fellow-scholar under Coustou. There is a want of simplicity in the works of this artist, from which the celebrated statue of Newton at Trinity-college, Cambridge, is by no means exempt. Mr. Nightingale's monument in Westminster-abbey, says Walpole, although finely thought and well executed, is more theatric than sepulchral.

At Christchurch are fine busts of Dr. Matthew Lee, Dr. R. Frewen, and one of the founders at All-souls.

Since the time of the foreign artists above mentioned, many eminent English sculptors have appeared, whose works are to be found in our churches and other public buildings. Wilton, Nollekens, Banks, Bacon, Flaxman, Westmacott, are some of the most conspicuous names of our modern school. Wilton executed some good monuments in Westminster-abbey; Nollekens has established a fame which has stood the test of a long life of constant practice, and remains undiminished.

The characteristic merits of Banks and Bacon are thus described by Mr. Hoare, in his inquiry into the State of The Arts in England. "Banks was among those who most zealously sought the enlargement of professional knowledge in the stores of Rome. A mind ardently roused to competition with the works of excellence which he beheld, and a hand trained from infancy to a ready expression of his conceptions, imparted to his productions an air of antient art.

"Bacon's genius was of native growth; he traversed no distant regions for improvement of his art, but drew from the researches of others sufficient food for an active and ready fancy. His conceptions were quick and sparkling, his execution polished, and his whole work characteristically graceful."

The sculpture of Flaxman denotes a chaste and correct taste, founded on the most critical study of the works of Grecian art.

Westmacott is an able pupil of the Venetian Canova.

England also boasts her female sculptors. The Hon. Mrs. Damer, and the illustrious a tress Siddons, have shewn distinguished talents in this art.

SCURVY. See Medicine, Vol. II. p. 154, col. 2.

SCUTAGE was antiently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army: hence scutagio habendo was a writ that lay for the king, or other lord, against tenants holding by knight's service, to serve in person, or send a sufficient man in their room, or pay a certain sum, &c.

SCUTELLARIA, *scull-cap*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is short, tubulated, has the mouth entire, and close after flowering. There are two species in Britain, the galericulata and minor. 1. The galericulata, blue scull-cap, or hooded willow-herb. It grows on the banks of rivers and lakes, is bitter, and has a garlic smell. 2. Minor, little red scull-cap, or willow-herb. The stalks are about eight inches high; the leaves are heart-shaped, oval; the flowers are purple. It grows in fens, and on the sides of lakes. There are fourteen other species.

SCUTTLES, in a ship, square holes cut in the deck, big enough to let in the body of a man, serving to let people down into any room below upon occasion, or from one deck to another. They are generally before the main-mast, before the knight in the fore-castle; in the gun-room, to go down to the stern-sheets; in the round-house, to go down into the captain's cabin, when forced by the enemy in a fight aloft. There are also some smaller scuttles, which have gratings over them: and all of them have covers that people may not fall down through them in the night.

Scuttle is also a name given those little windows and long holes which are cut out in cabins to let in light.

SCYLLARUS, a genus of insects, according to Fabricius, of the order aptera; but by the Linnæan system it is ranked with the genus cancer. See Plate Nat. Hist. fig. 358.

SCYLLÆA, a genus of insects of the order vermes mollusca. The generic character is, body compressed, and grooved along the back; mouth consisting of a terminal toothless aperture; tentacula three on each side, and placed beneath. There are two species.

SCYTHROPS, a genus of birds of the order picæ. The generic character is, bill large, convex, sharp-edged, channelled at the sides, hooked at the point; nostrils naked, rounded at the base of the bill; tongue cartilaginous, split at the point; feet climbers. There is but a single species, viz. the psittacus, which inhabits New South Wales; the size of a crow, but from the length of the tail measures 26 inches long.

SEA, in a strict sense, signifies a large portion of water almost surrounded by land, as the Baltic and Mediterranean seas; but it is frequently used for that vast body of water which encompasses the whole earth. See Ocean.

What proportion the superficies of the sea bears to that of the land, cannot easily be ascertained. Buffon has supposed that the surface of our globe is equally divided between land and water, and has accordingly calculated the superficies of the sea to be 85,490,506 square miles. But it is now well known that the ocean covers much more than half of the earth's surface. Buffon believed the existence of a vast southern continent, which captain Cook has shewn to be visionary. It was this circumstance which misled him. According to the most accurate observations hitherto made, the surface of the sea is to the land as three to one; the ocean, therefore, extends over 128,235,759 square miles, supposing the superficies of the whole globe to be 170,981,012 square miles. To ascertain the depth of the sea is still more difficult than its superficies; both on account of the numerous experiments which it would be necessary to make, and the want of proper instruments for that purpose. Beyond a certain depth the sea has hitherto been found unfathomable; and though several very ingenious methods have been contrived to obviate this difficulty, none of them has completely answered the purpose. We know in general that the depth of the sea increases gradually as we leave the shore; but if this continued beyond a certain distance, the depth in the middle of the ocean would be prodigious. Indeed the numerous islands every where scattered in the sea demonstrate the contrary, by showing us that the bottom of the water is unequal like the land; and that, so far from uniformly sinking, it sometimes rises into lofty mountains. If the depth of the sea is in proportion to the elevation of the land, as has generally been supposed, its greatest depth will not exceed five or six miles, for there is no mountain six miles perpendicular above the level of the sea. The sea has never been actually sounded to a greater depth than a mile and sixty-six feet; every thing beyond that therefore rests entirely upon conjecture and analogical reasoning, which ought never to be admitted to determine a single point that can be ascertained by experiment, because, when admitted, they have too often led to false conclusions. Along the coasts, where the depth of the sea is in general well known, it has always been found proportioned to the height of the shore: when the coast is high and mountainous, the sea that washes it is deep; when, on the contrary, the coast is low, the water is shallow. Whether this analogy holds at a distance from the shore, experiments alone can determine.

To calculate the quantity of water contained in the sea, while its depth is unknown, is impossible. But if we suppose with Buffon that its medium depth is the fourth part of a mile, the ocean, if its superficies is 128,235,759 square miles, will contain 32,058,939,75 cubic miles of water.

Let us now endeavour to compute the quantity of water which is constantly discharged into the sea. For this purpose let us take a river whose velocity and quantity of water are known, the Po, for instance, which, according to Riccioli, is 1000 feet (or 100 perches of Boulogne) broad, ten feet deep, and runs at the rate of four miles in an hour; consequently that river discharges into the sea 200,000 cubic perches of water in an hour, or 4,800,000 in a day. A cubic mile contains 125,000,000 cubic perches; the Po therefore will take twenty-six days to discharge a cubic mile of water into the sea. Let us now suppose, what is perhaps not very far from the truth, that the quantity of water which the sea receives from the rivers in any country is proportioned to the extent of that country. The Po from its origin to its mouth traverses a country 380 miles long, and the rivers which fall into it on every side rise from sources about sixty miles distant from it. The Po, therefore, and the rivers which it receives, water a country of 45,600 square miles. Now since the whole superficies of the dry land is about 42,745,253 square miles, it follows, from our supposition, that the quantity of water discharged by all the rivers in the world, in one day, is thirty-six cubic miles. If, therefore, the sea contains 32,058,939 cubic miles of water, it would take all the rivers in the world 2439 years to discharge an equal quantity.

It may seem surprising that the sea, since it is continually receiving such an immense supply of water, does not visibly increase, and at last cover the whole earth. But our surprise will cease, if we consider that the rivers themselves are supplied from the sea, and that they do nothing more than carry back those waters which the ocean is continually lavishing upon the earth. Dr. Halley has demonstrated that the vapours raised from the sea and transported upon land are sufficient to maintain all the rivers in the world. The simplicity of this great process is astonishing: the sea not only connects distant countries, and renders it easy to transport the commodities of one nation to another, but its waters rising in the air descend in showers to fertilise the earth and nourish the vegetable kingdom, and collecting into rivers flow onwards, bringing fertility and wealth and commerce along with them, and again return to the sea to repeat the same round.

As the sea covers so great a portion of the globe, we should no doubt, by exploring its bottom, discover a vast number of interesting particulars. Unfortunately, in the greater part of the ocean this has hitherto been impossible. Part, however, has been examined; and the discoveries which this examination has produced may enable us to form some idea at least of the whole. The bottom of the sea, as might have been conjectured indeed beforehand, bears a great resemblance to the surface of the dry land, being, like it, full of plains, rocks, caverns, and mountains; some of which are abrupt and almost perpendicular, while others rise with a gentle declivity, and sometimes tower above the water and form islands. Neither do the materials differ which compose the bottom of the sea and the basis of the dry land. If we dig to a considerable depth in any part of the earth, we uniformly meet with rock; the same thing holds in the sea. The strata too are of the same kind, disposed in the same manner, and form indeed but one whole. The same kind of mineral and bituminous substances are also found interspersed with these strata; and it is to them probably that the sea is indebted for its bitter taste. Over these natural and original strata an artificial bed has pretty generally been formed, composed of different materials in different places. It consists frequently of muddy tartareous substances firmly cemented together, sometimes of shells or coral reduced to powder, and near the mouths of rivers it is generally composed of fine sand or gravel.

The ocean differs more in saltness in different climates towards the equator than nearer the poles. This seems to arise from the different quantities of water which are evaporated, in proportion to those which fall in rain. One pound of sea-water in the Baltic yields about a quarter of an ounce of salt; near Holland half an ounce; and in the British seas about two ounces. Boyle has also observed, that in places of great depth the water is saltest at the bottom.

In the voyage made towards the north pole in 1773, it was found that the sea-water at the Nore contained not quite one thirty-sixth of salt; at the back of Yarmouth sands, not quite one thirty-second; off Flamborough Head, rather more than one twenty-ninth; off Scotland, rather less than one twenty-ninth; latitude 74°, at sea, one twenty-ninth; and in latitude 78°, rather less than one twenty-eighth.

The cause of the saltness of the ocean has been a subject of investigation among philosophers in almost all ages, but it still remains in great obscurity. There can be little doubt that a large quantity of saline matter existed in this globe from the creation; and, at this day, we find immense beds of sal gem, or common salt, buried in the earth, particularly at Cracow; but whether these collections have been derived from the ocean, and deposited in consequence of the evaporation of its waters in certain circumstances; or whether the ocean was itself originally fresh, and received its salt from collections of saline matter situated at its bottom, or from that brought by the influx of rivers; cannot now be ascertained. No accurate observations on the degree of saltness of the ocean in particular latitudes were made till the present century, and it is not possible, therefore, to ascertain what was the state of the sea at any considerable distance of time, nor, consequently, whether its degree of saltness increases, decreases, or is stationary. From differences among aquatic animals, however, some of which seem adapted to salt water, and some to fresh, it is probable, that both these states of water existed from the creation of the world. We know, it is true, that some kinds of fish, as salmon, are capable of existing both in fresh and in salt water, and that habit has a powerful influence over all animals; but this is not sufficient to refute the main fact, that some kinds of fish thrive only in salt water, others in fresh; some in standing pools, and others in rapid currents.

That excellent philosopher and chemist, the bishop of Landaff, has recommended a most simple and easy mode of ascertaining the saltness of the sea in any latitude; and as the language, in point of perspicuity and correctness, cannot be improved, we take the liberty of inserting it in his own words:

"As it is not every person who can make himself expert in the use of the common means of estimating the quantity of salt contained in sea-water, I will mention a method of doing it which is so easy and simple, that every common sailor may understand and practise it, and which, from the trials I have made of it, seems to be as exact a method as any that has yet been thought of. Take a clean towel or any other piece of cloth, dry it well in the sun or before the fire, then weigh it accurately, and note down its weight; dip it in the sea water, and when taken out, wring it a little till it will not drip, when hung up to dry; weigh it in this wet state, then dry it either in the sun or at the fire, and, when it is perfectly dry, weigh it again. The excess of the weight of the wetted cloth above its original weight, is the weight of the sea-water imbibed by the cloth; and the excess of the weight of the cloth after being dried, above its original weight, is the weight of the salt retained by the cloth; and by comparing this weight with the weight of the sea-water imbibed by the cloth, we obtain the proportion of salt contained in that species of sea-water.

"Whoever undertakes to ascertain the quantity of salt, contained in sea-water, either by this or any other method, would do well to observe the state of the weather preceding the time when the sea-water is taken out of the sea, for the quantity of salt contained in the water near the surface may be influenced both by the antecedent moisture and the antecedent heat of the atmosphere."

Whether the sea is salter or not at different depths, notwithstanding Mr. Boyle's observations before quoted, has not yet been properly ascertained; but that its temperature varies considerably in proportion to the depth we have decisive proof.

"With respect to the temperature," says bishop Watson, "of the sea at different depths, it seems reasonable enough to suppose, that in summer time it will be hotter at the surface than at any considerable depth below it, and that in winter it will be colder.

"Mr. Wales describes the instrument he made use of for trying the temperature of the sea at different depths, in the following terms: 'The apparatus for trying the sea-water at different depths consisted of a square wooden tube of about eighteen inches long and three inches square externally. It was fitted with a valve at the bottom, and another at the top, and had a contrivance for suspending the thermometer exactly in the middle of it. When it was used it was fastened to the deep sea-line, just above the lead, so that all the way as it descended the water had a free passage through it, by means of the valves which were then both open; but the instant it began to be drawn up, both the valves closed by the pressure of the water, and of course the thermometer was brought up in a body of water of the same temperature with that it was let down to.' With this instrument, which is much the same with one formerly described by Mr. Boyle, in his observations about the saltness of the sea, water was fetched up from different depths, and its temperature accurately noticed, in different seasons and latitudes.

"August 27, 1772, south latitude 24°. 40′. The heat of the air was 72½,—of the water at the surface 70,—of water from the depth of 80 fathoms 68.

"December 27, 1772, south latitude 58°, 21′. The heat of the air was 31,—of the water at the surface 32,—of water from the depth of 160 fathoms 33¼.

"In the voyage to the high northern latitudes before mentioned, they made use of a bottle to bring up water from the bottom, which is thus described: 'The bottle had a coating of wool, three inches thick, which was wrapped up in an oiled skin, and let into a leather purse, and the whole inclosed in a well-pitched canvas bag, firmly tied to the mouth of the bottle, so that not a drop of water could penetrate to its surface. A bit of lead shaped like a cone, with its base downwards, and a cord fixed to its small end, was put into the bottle; and a piece of valve leather, with half a dozen slips of thin bladder, were strung on the cord, which, when pulled, effectually corked the bottle on the inside.' We have here put down two of the experiments which were made during that voyage.

"August 4, 1773, north latitude 80°. 30′. The heat of the air was 32,—of the water at the surface 36,—of water fetched up from the depth of 60 fathoms under the ice 39.

"September 4, 1773, north latitude 65°. The heat of the air was 66½, of the water at the surface 55,—of water from the depth of 683 fathoms 40.

"It appears from all these experiments that, when the atmosphere was hotter than the surface of the sea, the superficial water was hotter than that at a great depth; and when the atmosphere was colder than the surface of the sea, it is evident that the superficial water was somewhat colder than at a considerable distance below it."

Sea-water may be rendered fresh by freezing, which excludes or precipitates the saline particles; or by distillation, which leaves the salt in a mass at the bottom of the vessel. Upon these principles, a mode of obtaining a supply of fresh water at sea was recommended some years ago to the admiralty, by Dr. Irving. It consisted in only adapting a tin tube of suitable dimensions to the lid of the common ship's kettle, and condensing the steam in a hogshead which served as a receiver. By this mode a supply of twenty-five gallons of fresh water per hour might be obtained from the kettle of one of our ships of war.

The sea shall be open by the laws of England, to all merchants. The main sea beneath the low-water mark, and round England, is part of England, for there the admiralty has jurisdiction. 1 Inst. 260.

SEAL, is either in wax, impressed with a device and attached to deeds, &c. or the instrument with which the wax is impressed. Sealing of a deed, is an essential part of it; for if a writing is not sealed, it cannot be a deed. See DEED.

SEALER, an officer in chancery, appointed by the lord chancellor or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEALING, in architecture, the fixing a piece of wood or iron in a wall with plaister, mortar, cement, lead, and other solid binding.

SEAMEN: by various statutes, sailors having served the king for a limited time, are free to use any trade or profession, in any town of the kingdom, except in Oxford or Cambridge.

By 2 Geo. II. c. 36, made perpetual by 2 Geo. III. c. 31, no master of any vessel shall carry to sea any seaman, his own apprentices excepted, without first entering into an agreement with such seaman for his wages: such agreement to be made in writing, and to declare what wages such seaman is to receive during the whole of the voyage, or for such time as shall be therein agreed upon; and such agreement shall also express the voyage for which such seaman was shipped to perform the same. The provisions of this act are enforced by a penalty of ten pounds for each mariner carried to sea without such agreement, to be forfeited by the master to the use of Greenwich-hospital. This agreement is to be signed by each mariner within three days after entering on board such ship, and is, when executed, binding on all parties.

SEAM or SEME *of corn*, is a measure of eight bushels.

SEAM *of glass*, the quantity of 120 pound, or 24 stones each five pounds weight. The seam of wood is a horse-load.

SEAMS *of a ship*, are places where her planks meet and join together. There is also a kind of peculiar seam in the sowing of sails, which they call monk-seam; the other seam of a sail is the round seam, so called from its being round like the common seams.

SEARCHER, an officer of the customs, whose business is to search and examine all ships outward-bound, to see whether they have any prohibited or unaccustomed goods on board.

SEASIN, or SEASING, in a ship, the name of a rope by which the boat rides by the ship's side when in the harbour, &c.

SEBATS. As the sebacic acid was, strictly speaking, unknown till the late experiments of Thenard, the description of the sebats published by former chemists cannot be admitted as exact till they are verified by a new examination. These salts of course are unknown, if we except the few facts pointed out by Thenard. This chemist, however, has announced his intention of publishing a detailed account of them.

1. When sebacic acid is dropt into barytes water, lime water, or strontian water, it does not render these liquids turbid. Hence we learn, that the sebats of the alkaline earths are soluble in water.

2. The alkaline sebats are likewise soluble. Sebat of potass has little taste, does not attract moisture from the air; and when sulphuric, nitric, or muriatic acid is poured upon it, sebacic acid is deposited. When the concentrated solution of this salt is mixed with any of these acids, it becomes solid from the crystallization of the sebacic acid.

SEBACIC ACID. Chemists had long suspected that an acid could be obtained from tallow, on account of the acrid nature of the fumes which it emits at a high temperature; but it was M. Grutzmacher who first treated of it particularly in a dissertation De Ossium Medulla, published in 1748. Mr. Rhodes mentioned it in 1753; Segner published a dissertation on it in 1754; and Crell examined its properties very fully in two dissertations published in the Philosophical Transactions for 1780 and 1782. It was called at first acid of fat, and afterwards sebacic acid.

But at the period when these chemists made their experiments, the characteristic properties of the different acids were not sufficiently known to enable them to distinguish acids from each other with precision. Thenard examined the subject in 1801, tried all the processes of Crell and Guyton Morveau, and found that the acids procured by them were either acetic, or the acid employed in the process. Real sebacic acid had hitherto escaped the examination of chemists. It may be procured by the following method, for which we are indebted to Thenard.

1. Distil hog's lard, wash the product with hot water, separate this water, and drop into it acetat of lead. A flaky precipitate appears, which is to be washed and dried, mixed with sulphuric acid, and heated. A melted substance analogous to fat, swims on the surface, which is to be carefully separated. This substance is sebacic acid. It may be dissolved in hot water, and on cooling crystalline needles are deposited. This acid may be obtained also by evaporating the water employed in washing the product of distilled hog's lard. Or this water may be saturated with potass, and afterwards precipitated with acetat of lead as above. Its properties are the following.

2. It has no smell, its taste is slightly acid, and it reddens the tincture of turnsole. When heated it melts like tallow. It is soluble in cold, but much more soluble in hot water. Boiling water saturated with it becomes solid on cooling; alcohol also dissolves it abundantly. It crystallizes in needles; but by proper precautions it may be obtained in long, large, and very brilliant plates.

It occasions a precipitate in the acetat and nitrat of lead, the nitrat of silver, the acetat and nitrat of mercury. It forms peculiar salts with the alkalies and earths. It does not render lime water, barytes, or strontian water turbid. Sebat of potass has little taste, does not attract moisture from the air; and when sulphuric, nitric, or muriatic acid is poured upon it, sebacic acid is deposited: when its solution is concentrated and mixed with any one of these acids it becomes solid.

SECALE, *rye*, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is a glume of two leaves, which are opposite to one another, erect, linear, pointed, and less than the corolla. The corolla consists of two valves, the exterior of which ends in a beard. There are four species: the villosum, orientale, creticum, and cercale. The villosum, or wood rye-grass, is distinguished by a calyx with wedge-shaped scales, and by the fringe of the glume being woolly. The glumes of the orientale are shaggy, and the scales of the calyx are shaped like an awl. The glumes of the creticum are fringed on the outside. The cereale, or common rye, has glumes with rough fringes. It is a native of the island of Candia, was introduced into England many ages ago, and is the only species of rye cultivated in this kingdom. There are, however, two varieties, the winter and spring rye.

The winter rye, which is larger in the grain than the spring rye, is sown in autumn at the same time with wheat, and sometimes mixed with it; but as the rye ripens sooner than the wheat, this method must be very exceptionable. The spring rye is sown along with the oats, and usually ripens as soon as the winter rye; but the grain produced is lighter, and it is therefore seldom sown except where the autumnal crop has failed.

Rye is commonly sown on poor, dry, limestone, or sandy soils, where wheat will not thrive. By continuing to sow it on such a soil for two or three years, it will at length ripen a month earlier than that which has been raised for years on strong cold ground.

Rye is commonly used for bread either alone or mixed with wheat. This mixture is called meslin, and was formerly a very common crop in some parts of Britain. Mr. Marshall tells us, that the farmers in Yorkshire believe that this mixed crop is never affected by mildew, and that a small quantity of rye sown among wheat will prevent this destructive disease. Rye is much used for bread in some parts of Sweden and Norway by the poor people. About a century ago rye-bread was also much used in England; but being made of a black kind of rye, it was of the same colour, clammy, very detergent, and consequently not so nourishing as wheat.

Rye is subject to a disease which the French call ergot, and the English horned rye; which sometimes happens when a very hot summer succeeds a rainy spring. According to Tissot, horned rye is such as suffers an irregular vegetation in the middle substance between the grain and the leaf, producing an excrescence of a brownish colour, about an inch and a half long, and two-tenths of an inch broad. Bread made of this kind of rye has a nauseous acrid taste, and produces spasmodic and gangrenous disorders.

SECANT, in geometry, is a line that cuts another, or divides it into two parts. See TRIGONOMETRY.

SECHIUM, a genus of the syngenesia order, in the monœcia class of plants; and in the natural method ranking under the 34th order, cucurbitaceæ. The male calyx is quinquedentate and monophyllous; the corolla monopetalous; the five filaments are united in an erect tube. In the female flower the pistillum is cylindrical and erect; the stigma large, peltated, and reflected; the pericarpium large, oval, unequal, fleshy, and unilocular, containing one seed, which is smooth, compressed, and fleshy. Of this there is only one species, viz. the edulis, or chocho vine. This is cultivated and grows very luxuriantly in many places in Jamaica. The vines run and spread very much. The fruit is boiled, and served up at table by way of greens; and the root of the old vine is somewhat like a yam (dioscorea), and on being boiled or roasted tastes farinaceous and wholesome.

SECOND, in geometry, chronology, &c. the sixtieth part of a prime or minute, whether of a degree, or of an hour: it is denoted by two small accents, thus (″).

SECOND, in music, an interval of a conjoint degree. There are four kinds of seconds. The diminished second, containing four commas; the minor second, consisting of five commas; the major second, consisting of nine commas; and the redundant second, composed of a whole tone and a minor semitone.

SECONDARY, in general, something that acts as second, or in subordination to another. Secondary circles of the sphere, are circles passing through the poles of some great circle: thus the meridians and hour-circles are secondaries to the equinoctial. There are also secondaries passing through the poles of the ecliptic, by means of which all stars are referred to the ecliptic.

SECONDARY, an officer who is second, or next to the chief officer; as the secondaries to the prothonotaries in the courts of B. R. and C. B.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders authentic by his signet. Of these there are several kinds; as, 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king: they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign: which when read, are returned to them; all which they dispatch according to the direction of the king in council. They have authority to commit persons for treason, and other offences against the state, as conservators of the peace at common law, or as justices of the peace throughout the kingdom. They are members of the privy and cabinet council, which is seldom or never held without one of them being present; as to the business and correspondence in all parts of this kingdom, it is managed by the secretary for the home department. With respect to foreign affairs, the business is in the foreign office. There has been lately established a secretary of state for the war department, which must not be confounded with the secretary at war. The secretaries have each two under-secretaries, and one chief clerk. To the secretaries of state belong the custody of that seal properly called the signet, and the direction of two other offices, one called the paper-office, and the other the signet-office. See PAPER-OFFICE and SIGNET-OFFICE.

2. Secretary of an embassy, a person attending an ambassador for writing dispatches relating to the negotiation. There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or menial of the ambassador, and the first, a servant or minister of the prince. 3. The secretary at war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger. There are also secretaries in most of the other offices.

SECRETION, in the animal economy, the separation of some fluid mixed with the blood by means of the glands. See PHYSIOLOGY.

SECRETIONS, *morbid*. In different diseases to which the animal body is subject, various fluids make their appearance which did not previously exist, at least under the forms which they assume. Thus in the dropsy the cellular substance, frequently the cavities of the head, breast, or abdomen, are filled with a whitish liquid. Where any part of the skin is irritated into a blister, the interval between the cutis and cuticle is filled with a transparent fluid; and when any part of the muscles or skin is wounded, the ulcer is soon covered with a matter called pus. See PUS. A thin sanies exudes from cancers and carious bones. The liquor of the dropsy is found upon examination to agree almost exactly with the serum of the blood. The liquor of blisters is composed also of the same constituents as the serum of blood: from 200 parts has been obtained by chemical analysis

36 albumen,
4 muriat of soda,
2 carbonat of soda,
2 phosphat of lime,
156

200.

SECTION, in geometry, denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

The common section of two planes is always a right line; being the line supposed to be drawn on one plane by the section of the other, or by its entrance into it.

SECTION *of a building*, in architecture, is the same with its profile; or a delineation of its heights and depths raised on a plane, as if the fabric was cut asunder to discover its inside.

SECTIONS, *conic*, in geometry. See CONIC SECTION.

SECTOR, in geometry, is a part of a circle, comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle.

SECTOR. See INSTRUMENTS MATHEMATICAL.

SECUNDINES. See MIDWIFERY.

SECURIDACA, a plant belonging to the class of diadelphia, and to the order of octandria. The calyx has three leaves, which are small, deciduous, and coloured. The corolla is papilionaceous. The vexillum, consisting of two petals, is oblong, straight, and conjoined to the carina at the base. The carina is of the same length with the alæ. The legumen is ovated, unilocular, monospermous, and ending in a legulated ala. There are three species. The erecta has an upright stem: the scandens is a climbing plant, and is a native of the West Indies.

SECUTORES, in antiquity, a kind of gladiators among the Romans, who fought against the retiarii. The secutores were armed with a sword and buckler, to keep off the net or noose of their antagonists, and they wore a cask on their head.

SEDATIVES. See Materia Medica, vol. II. p. 110, col. 2, *Narcotics*.

SE DEFENDENDO, in law, a plea used for him that is charged with the death of another, by alleging that he was under a necessity of doing what he did in his own defence; as that the other assaulted him in such a manner, that if he had not done what he did, he must have been in hazard of his own life. But here the danger must appear so great, as to be inevitable. See Homicide.

SEDITION, among civilians, is used for a factious commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of the society. This offence is of different kinds: some seditions more immediately threatening the supreme power, and the subversion of the present constitution of the state; others tending only towards the redress of private grievances. Among the Romans, therefore, it was variously punished, according as its end and tendency threatened greater mischief. See lib. i. God. de Seditiosis, and Mat. de Crimin. lib. ii. n. 5. de Læsa Majestate. In the punishment, the authors and ringleaders were justly distinguished from those who, with less wicked intentions, joined and made part of the multitude.

The same distinction holds in the law of England and in that of Scotland. Some kinds of sedition in England amount to high treason, and come within the stat. 25 Edw. III. as levying war against the king. And several seditions are mentioned in the Scotch acts of parliament as treasonable. Bayne's Crim Law. of Scotland, p. 33, 34. The law of Scotland makes riotous and tumultuous assemblies a species of sedition. But the law there, as well as in England, is now chiefly regulated by the riot act, made 1 Geo. I. only it is to be observed, that the proper officers in Scotland, to make the proclamation thereby enacted, are sheriffs, stewards, and bailies of regalities, or their deputies; magistrates of royal boroughs, and all other inferior magistrates; high and petty constables, or other officers of the peace, in any county, stewartry, city, or town. And in that part of the island, the punishment of the offence is any thing short of death which the judges, in their discretion, may appoint.

SEDUM, *orpine*, a genus of the pentagynia order, in the decandria class of plants; and in the natural method ranking under the 13th order, succulentæ. The calyx is quinquefid; the corolla is pentapetalous, pointed, and spreading; there are five nectariferous squamæ, or scales, at the base of the germen. The capsules are five.

The species are 30. The most noted are, 1. The verticillatum; 2. Telephium; 3. Anacampseros; 4. Aizoon; 5. Hybridum; 6. Populifolium; 7. Stellatum; 8. Cepaea, 9. Libanoticum; 10. Dasyphyllum; 11. Reflexum; 12. Rupestre; 13 Lineare; 14. Hispanicum; 15. Album; 16. Acre; 17. Sexangulare; 18. Annuum; 19. Villosum; 20. Atratum.

All these species of sedum are hardy herbaceous succulent perennials, durable in root but mostly annual in stalk, &c. which, rising in spring, flower in June, July, and August, in different sorts; the flowers consisting universally of five spreading petals, generally crowning the stalks numerously in corymbose and cymose bunches and spikes, appearing tolerably conspicuous, and are succeeded by plenty of seeds in autumn, by which they may be propagated, also abundantly by parting the roots, and by slips or cuttings of the stalks in summer; in all of which methods they readily grow, and spread very fast into tufted bunches: being all of succulent growth, they consequently delight most in dry soils, or in any dry rubbishy earth.

As flowering plants, they are mostly employed to embellish rock-work, ruins, and the like places; planting either the roots or cuttings of the shoots in a little mud or any moist soil at first, placing it in the crevices, where they will soon root and fix themselves, and spread about very agreeably. For economical purposes, the reflexum and rupestre are cultivated in Holland and Germany, to mix with lettuce in sallads. The wall-pepper is so acrid, that it blisters the skin when applied externally. Taken inwardly, it excites vomiting. In scorbutic cases and quartan agues, it is said to be an excellent medicine under proper management. Goats eat it; cows, horses, sheep, and swine, refuse it.

SEED. See Plants, Physiology, and Semen.

SEELING, at sea, is used in the same sense nearly with heeling: when a ship lies down constantly, or steadily on one side, the seamen say, she heels; and they call it seeling when she tumbles violently and suddenly, by the sea forsaking her, as they call it, that is, the waves leaving her for a time in a bowling sea.

SEGMENT *of a circle*. See Geometry.

Segment *of a sphere*, is a part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the centre; being more properly called the section of a sphere.

The base of a segment is always a circle. And the convex surfaces of different segments, are to each other as their altitudes, or versed sines. And as the whole convex surface of the sphere is equal to four of its great circles, or four circles of the same diameter; so the surface of any segment is equal to four circles on a diameter equal to the chord of half the arc of the segment. So that if d denotes the diameter of the sphere, or the chord of half the circumference, and c the chord of half the arc of any other segment, also a the altitude or versed sine of the same; then,

$3.1416d^2$ is the surface of the whole sphere, and

$3.1416c^2$, or $3.1416d$, the surface of the segment.

For the solid content of a segment, there are two rules usually given; viz. 1. To three times the square of the radius of its base, add the square of its height; multiply the sum by the height, and the product by .5236. Or, 2dly, From three times the diameter of the sphere, subtract twice the height of the frustum; multiply the remainder by the square of the height, and the product by .5236.

That is, in symbols, the solid content is either $= .5236a \times \overline{3r^2 + a^2}$, or $= \cdot 5236a^2 \times \overline{3d - 2a}$; where a is the altitude of the segment, r the radius of its base, and d the diameter of the whole sphere.

SEGUERIA, in botany, a plant belonging to the class of polyandria and the order of monogynia. The calyx is pentaphyllous; the phylla are oblong, concave, coloured, and permanent; there is no corolla. The capsule is oblong and monospermous, the large ala terminating in small lateral alæ. There are two species, the Americana and Asiatic.

SEIGNIORY, dominium, in our law, is used for a manor or lordship of a seigneur, or lord of the fee or manor.

SEIGNORAGE, signifies the right, or due belonging to a seigneur, or lord; but it is particularly used for a duty belonging to the prince, for the coining of money, called also coinage; which under our antient kings was five shillings for every pound of gold brought in the mass to be coined, and a shilling for every pound weight of silver. At present the king claims no seignorage at all, but the subject has his money coined at the public expence; nor has the king any advantage, but what he has from the alloy. See Coining.

SEISIN, in law, signifies possession. Seisin is two-fold; seisin in law, and seisin in fact. Seisin in fact, is when an actual possession is taken; seisin in law, when something is done which the law accounts a seisin, as an enrollment.

SEIZE, Seaze, or Sease, in the sea-language, is to make fast, or bind, particularly to fasten two ropes together, with rope-yarn. The seizing of a boat is a rope tied to a ring, or little chain in the foreship of the boat, by which means it is fastened to the side of the ship.

SEIZURE, in commerce, an arrest of some merchandize, moveable, or other matter, either in consequence of some law, or of some express order of the sovereign. Contraband goods, those fraudulently entered, or landed without entering at all, or at wrong places, are subject to seizure. In seizures, among us, one half goes to the informer, and the other half to the king.

SELAGO, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 48th order, aggregatæ. The calyx is quinquefid: the tube of the corolla capillary, with the limb nearly equal, and a single seed. There are 20 species.

SELENITE, in chemistry. See Sulphat of Lime.

Selenites, in natural history, the name of a large class of fossils, the characters of which are these: they are bodies composed of slender and scarce visible filaments, arranged into fine, even, and thin flakes; and those disposed into regular figures in the several different genera, approaching to a rhomboid or hexangular column, or a rectangled parallelogram; fissile, like the talcs, but they not only lie in a horizontal, but also in a perpendicular direction; they are flexile in a small degree, but not at all elastic; they do not ferment with acid menstrua, but readily calcine in the fire. Of this class there are seven orders of bodies, and under those ten genera. The selenitæ of the first order are those composed of horizontal plates, and approaching to a rhomboidal form: of the second are those composed of horizontal plates, arranged into a columnar and angular form: of the third are those whose filaments are scarce visibly arranged into plates, but which, in the whole masses, appear rather of a striated than of a tubulated structure: of the fourth are those which are flat, but of no determinately angular figure: of the fifth are those formed of plates perpendicularly arranged: of the sixth are those formed of congeries of plates, arranged into the figure of a star; and of the seventh are those of a complex and indeterminate figure.

The structure of the selenitæ of all the genera of the first order is exactly alike; they are all composed of a great number of broad flakes or plates, in a great measure externally resembling the flakes of the foliaceous talcs: these are of the length and breadth of the whole mass; the top and bottom being each only one such plate, and those between them, in like manner, each complete and single; and the body may always be easily and evenly split, according to the direction of these flakes. These differ, however, extremely from the talcs; for they are each composed of a number of parallel threads or filaments, which are usually disposed parallel to the sides of the body, though sometimes parallel to its ends. In many of the species they are also divided by parallel lines, placed at a considerable distance from each other, and the plates in splitting often break at these lines; add to this, that they are not elastic, and that they readily calcine. The structure of those of the second is the same with that of the first: but that in many of the specimens of them, the filaments of which the plates are composed run in two directions, and meet in an obtuse angle; and in the middle there is generally seen in this case a straight line running the whole length of the column; and small parcels of clay insinuating themselves into this crack, represent in it the figure of an ear of grass so naturally, as to have deceived many into a belief that there was really an ear of grass there. The other orders consisting only of single genera, the structure of each is explained under the generical name. See Plate Nat. Hist. fig. 359.

SELEUCIDÆ, in chronology: æra of the Seleucidæ, or the Syro-Macedonian æra, is a computation of time, commencing from the establishment of the Seleucidæ, a race of Greek kings, who reigned as successors of Alexander the Great, in Syria, as the Ptolemies did in Egypt. This æra we find expressed in the book of Maccabees, and on a great number of Greek medals, struck by the cities of Syria, &c. The rabbins call it the æra of contracts; and the Arabs therik dilkarnain, that is, the æra of the two horns. According to the best accounts, the first year of this æra falls in the year 311 before Christ, being twelve years after Alexander's death.

SELF-HEAL, the prunella vulgaris of Linnæus. The stem is erect, and about eight or ten inches high. The leaves grow on footstalks, are ovato-oblong, slightly indented, and somewhat hairy. The bracteæ are heart-shaped, opposite, and fringed. The flowers are white or purplish, grow in dense spikes, and are terminal. This plant is perennial, grows wild in meadows and pasture-grounds, and flowers in June and July. This herb is recommended as a mild restringent and vulnerary in spittings of blood, and other hemorrhages and fluxes; and in gargarisms against aphthæ and inflammations of the fauces. Its virtues do not appear to be very great; to the taste it discovers a very slight austerity or bitterishness, which is more sensible in the flowery tops than the leaves.

SELINUM, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is oval, oblong, compressed, plane, and striated in the middle: the involucrum is reflexed; the petals cordate and equal. There are nine species, the sylvestre, palustre, austriacum, carufolia, chabraci, seguieri, monnieri, sibiricum, and deceprens.

SELL, in building, is of two kinds, viz. ground-sell, which denotes the lowest piece of timber, in a timber building, and that on which the whole superstructure is raised; and the window-sell, called also window-soil, is the bottom pi ce in a window-frame.

SELLA EQUINA. See Anatomy.

SELTZER-WATER. See Waters, Mineral.

SEMECARPUS, a genus of the trigynia order, in the pentandria class of plants. The corolla is quinquepetalous; the drupa is heart-shaped, cellulous, and monospermous. There is but one species.

SEMEN, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. The peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is known by the name of semen. The human semen alone has hitherto been subjected to chemical analysis. Nothing is known concerning the seminal fluid of other animals. Vauquelin published an analysis of the human semen in 1791.

Semen, when newly ejected, is evidently a mixture of two different substances: the one, fluid and milky, which is supposed to be secreted by the prostate gland; the other, which is considered as the true secretion of the testes, is a thick mucilaginous substance, in which numerous white shining filaments may be discovered. It has a slight disagreeable odour, an acrid irritating taste, and its specific gravity is greater than that of water. When rubbed in a mortar it becomes frothy, and of the consistence of pomatum, in consequence of its enveloping a great number of air-bubbles. It converts paper stained with the blossoms of mallows or violets to a green colour, and consequently contains an alkali.

As the liquid cools, the mucilaginous part becomes transparent, and acquires greater consistency; but in about twenty minutes after its emission, the whole becomes perfectly liquid. This liquefaction is not owing to the absorption of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere; nor is it owing to the action of the air, for it takes place equally in close vessels.

Semen is insoluble in water before this spontaneous liquefaction, but afterwards it dissolves readily in it. When alcohol or oxymuriatic acid is poured into this solution, a number of white flakes are precipitated. Concentrated alkalies facilitate its combination with water. Acids readily dissolve the semen, and the solution is not decomposed by alkalies; neither indeed is the alkaline solution decomposed by acids.

Lime disengages no ammonia from fresh semen; but after that fluid has remained for some time in a moist and warm atmosphere, lime separates a great quantity from it. Consequently ammonia is formed during the exposure of semen to the air.

When oxymuriatic acid is poured into semen, a number of white flakes precipitate, and the acid loses its peculiar odour. These flakes are in oluble in water, and even in acids. If the quantity of acid is sufficient, the semen acquires a yellow colour. Thus it appears that semen contains a mucilaginous substance analogous to that of the tears, which coagulates by absorbing oygen. M. Vauquelin obtained from 100 parts of semen six parts of this mucilage.

When semen is exposed to the air about the temperature of 60°, it becomes gradually covered with a transparent pellicle, and in three or four days deposits small transparent crystals, often crossing each other in such a manner as to represent the spokes of a wheel. These crystals, when viewed through a microscope, appear to be four-sided prisms, terminated by very long four-sided pyramids. They may be separated by diluting the liquid with water, and decanting it off. They have all the properties of phosphat of lime. If, after the appearance of these crystals, the semen is still allowed to remain exposed to the atmosphere, the pellicle on its surface gradually thickens, and a number of white round bodies appear on different parts of it. These bodies also are phosphat of lime, prevented from crystallizing regularly by the too rapid abstraction of moisture. M. Vauquelin found that 100 parts of semen contain three parts of phosphat of lime. If at this period of the evaporation the air becomes moist, other crystals appear in the semen, which have the properties of carbonat of soda. The evaporation does not go on to complete exsiccation, unless at the temperature of 77°, and when the air is very dry. When all the moisture is evaporated, the semen has lost 0.9 of its weight; the residuum is semitransparent like horn, and brittle.

When semen is kept in very moist air, at the temperature of about 77°, it acquires a yellow colour, like that of the yolk of an egg; its taste becomes acid, it exhales the odour of putrid fish, and its surface is covered with abundance of the byssus septica.

When dried semen is exposed to heat in a crucible, it melts, acquires a brown colour, and exhales a yellow fume, having the odour of burnt horn. When the heat is raised, the matter swells, becomes black, and gives out a strong odour of ammonia. When the odour of ammonia disappears, if the matter is lixiviated with water, an alkaline solution may be obtained, which, by evaporation, yields crystals of carbonat of soda. M. Vauquelin found that 100 parts of semen contain one part of soda. If the residuum is incinerated, there will remain only a quantity of white ashes, consisting of phosphat of lime.

Thus it appears that semen is composed of the following ingredients:

90	water
6	mucilage
3	phosphat of lime
1	soda
100.	

SEMEN, *seed.* See BOTANY; and PLANTS, *physiology of.* With respect to number, plants are either furnished with one seed, as sea-pink and bistort; two, as wood-roof, and the umbelliferous plants; three, as spurge four, as the lip-flowers of Tournefort, and rough-leaved plants of Ray; or many, as ranunculus, anemone, and poppy. The form of seeds is likewise extremely various, being either large or small, round, oval, heart-shaped, kidney-shaped, angular, prickly, rough, hairy, wrinkled, sleek, or shining, black, white, or brown. Most seeds have only one cell or internal cavity; those of lesser burdock, valerian, lamb's lettuce, carnelian cherry, and sebesten, have two. With respect to substance, seeds are either soft, membranaceous, or of a hard bony substance; as in gromwell, tamarind, and all the nuciferous plants. In point of magnitude, seeds are either very large, as in the cocoa-nut, or very small, as in campanula, ammannia, rampions, and throatwort.

With respect to situation, they are either dispersed promiscuously through the pulp (semina nidulentia), as in water-lily; affixed to a suture or joining of the valves of the seed-vessel, as in the cross-shaped and pea-bloom flowers; or placed upon a placenta or receptacle within the seed-vessel, as in tobacco and thornapple.

Seeds are said to be naked, (semina nuda) which are not contained in a cover or vessel. Such are those of the lip and compound flowers, the umbelliferous and rough-leaved plants; covered seeds (semina tecta) are contained in some vessel, whether of the capsule, pod, berry, apple, or cherry kind.

A simple seed is such as bears neither crown, wing, nor downy pappus; the varieties in seeds arising from these circumstances are particularly enumerated under their respective heads.

In assimilating the animal and vegetable kingdoms, Linnæus denominates seeds the eggs of plants. The fecundity of plants is frequently marvellous; from a single plant or stalk of Indian Turkey wheat, are produced, in one summer, 2000 seeds; of elecampane 3000; of sun-flower 4000; of poppy 32,000; of a spike of cat's-tail 10,000, and upwards; a single fruit, or seed-vessel, of tobacco, contains 1000 seeds; that of white poppy 8000. Mr. Ray relates, from experiments made by himself, that 1012 tobacco-seeds are equal in weight to one grain; and that the weight of the whole quantum of seeds in a single tobacco-plant is such as must, according to the above proportion, determine their number to be 360,000. The same author estimates the annual produce of a single stalk of spleenwort to be upwards of one million of seeds.

The dissemination of plants respects the different methods or vehicles by which nature has contrived to disperse their seeds for the purpose of increase. These by naturalists are generally reckoned four:

1. Rivers and running waters. 2. The wind. 3. Animals. 4. An elastic spring, peculiar to the seeds themselves.

1. The seeds which are carried along by rivers and torrents are frequently conveyed many hundreds of leagues from their native soil, and cast upon a very different climate, to which, however, by degrees they render themselves familiar.

2. Those which are carried by the wind are either winged, as in fir-tree, trumpet-flower, tulip-tree, birch, arbor-vitæ, meadow-rue, and jessamine, and some umbelliferous plants, furnished with a pappus, or downy crown, as in valerian, poplar, reed, succulent swallow-wort, cotton-tree, and many of the compound flowers, placed within a winged calyx or seed-vessel, as in scabious, sea-pink, dock, dioscorea, ash, maple, and elm-trees, logwood, and woad; or, lastly, contained within a swelled calyx or seed-vessel, as in winter-cherry, cucubalus, melilot, bladder-nut, fumitory, bladder-sena, heart-seed, and chick-peas.

3. Many birds swallow the seeds of vaneloe, juniper, misletoe, oats, millet, and other grasses, and void them entire. Squirrels, rats, parrots, and other animals, suffer many of the seeds which they devour to escape, and thus in effect disseminate them. Moles, ants, earthworms, and other insects, by ploughing up the earth, admit a free passage to those seeds which have been scattered upon its surface. Again, some seeds attach themselves to animals, by means of hooks, crotchets, or hairs: which are either affixed to the seeds themselves, as in hound's-tongue, mouse-ear, vervain, carrot, bastard-parsley, sanicle, water-hemp, agrimony, arctopus, and verbesina; to their calyx, as in burdock, agrimony, rhexia, small wild bugloss, dock, nettle, pellitory, and lead-wort; or to their fruit or seed-vessel, as in liquorice, enchanter's nightshade, cross-wort, clivers, French honeysuckle, and arrow-headed grass.

4. The seeds which disperse themselves by an elastic force, have that force resident either in their calyx, as in oats, and the great number of ferns; in their pappus, as in centaurea crupina; or in their capsule, as in geranium, herb-bennet, African spiræ, fraxinella, horse-tail, balsam, Malabar-nut, cucumber, elaterium, and male balsam-apple.

SEMI-CIRCLE, in geometry, half a circle, or that figure comprehended between the diameter of a circle and half the circumference.

SEMI-COLON, in grammar, one of the points or stops used to distinguish the several members of sentences from each other.

SEMI-CUBICAL parabola, in the higher geometry, a curve of the second order, wherein the cubes of the ordinates are as the squares of the abscisses. Its equation is $axx = y$.

SEMI-DIURNAL. Of any of those circles which the sun appears to perform each daily revolution, that portion which is above the horizon is called the diurnal arch, and that which is below the horizon is called the nocturnal arch, the halves of which are called the semi-diurnal and the semi-nocturnal arches.

SEMI-OPAL. See OPAL.

SEMI-PARABOLA, in geometry, a curve defined by the equation $ax^{m-1} = y^m$; as $ax^2 = y^3$, and $ax^3 = y^4$. See the article PARABOLA.

In semi-parabolas, $y^m : v^m :: ax^{m-1} : az^{m-1} = x^{m-1} : z^{m-1}$; or the powers of the semi-ordinates are, as the powers of the semi-abscisses, one degree lower: for instance, in cubical semi-parabolas the cubes of the ordinates are as the squares of the abscisses; that is, $^3y : v :: x^2 : z^2$.

SEMI-PELAGIANS, in church history, a branch of the pelagians, so called because they pretended to keep a medium between the pelagians and the orthodox.

SEMPERVIVUM, *house-leek,* a genus of plants belonging to the order of dodecagynia, and to the class of dodecandria, and in the natural method ranking under the 13th order, succulentæ. The calyx is divided into 12 parts; the petals are twelve; and the capsules twelve, containing many seeds. There are fourteen species; the arboreum, canariense, glutinosum, glandulosum, tectorum, globiferum, villosum, tortuosum, arachnoideum, montanum, fedeforme, menanthus, stellatum, and histum. The tectorum alone is a native of Britain. It is frequent on the tops of houses, and flowers in July.

SENATUS AUCTORITAS, a vote of the Roman senate, drawn up in the same form with a decree, but without its force, as having been hindered from passing into a decree by some of the tribunes of the people.

SENATUS CONSULTUM, a decree of the Roman senate, pronounced on some question or point of law, which, when passed, made a part of the Roman law. See CIVIL LAW.

SENECIO, *groundsel,* a genus belonging to the class of syngenesia, and to the order of polygamia superflua, and in the natural classification ranked under the 49th order, compositæ. The receptacle is naked; the pappus simple; the calyx cylindrical and calyculated. The scales are equal and contiguous, so as to seem entire; those at the base are few, and have their apices or points decayed. There are 75 species. Of these, seven are British; the vulgaris, viscosus, sylvaticus, crucifolius, jacobæa, paludosus, and saracenicus.

SENTENCE, in grammar, a period or set of words comprehending some perfect sense or sentiment of the mind.

SEPIA, the *cuttle-fish,* a genus belonging to the order of vermes mollusca. There are eight brachia interspersed on the interior side, with little round serrated cups, by the contraction of which the animal lays fast hold of any thing. Besides these eight arms, it has two tentacula longer than the arms, and frequently pedunculated. The mouth is situated in the centre of the arms, and is horny and hooked. The eyes are below the tentacula, towards the body of the animal. The body is fleshy, and received into a sheath as far as the breast. Their food are tunnies, sprats, lobsters and other shell-fish. With their arms and trunks they fasten themselves, to resist the motion of the waves. Their beak is like that of a parrot. The females are distinguished by two paps. They copulate as the polypi do, by a mutual embrace, and lay their eggs upon sea-weed and plants, in parcels like bunches of grapes. Immediately after they are laid they are white, and the males pass over and impregnate them with a black liquor, after which they grow larger. On opening the egg, the embryo cuttle is found alive. The males are very constant, accompany their females every where, face every danger in their defence, and rescue them intrepidly at the hazard of their own lives. The timorous females fly as soon as they see the males wounded. The noise of a cuttle-fish, on being dragged out of the water, resembles the grunting of a hog. When the male is pursued by the sea-wolf, or other ravenous fish, he shuns the danger by stratagem. He squirts his black liquor, sometimesto the quantity of a dram, by which the water becomes black as ink, under shelter of which he baffles the pursuit of his enemy. This ink, or black liquor, has been denominated by M. Le Cat æthiops animal, and is reserved in a particular gland. In its liquid state it resembles that of the choroïd in man, and would then communicate an indelible dye; when dry, it might be taken for the product of the black liquor in negroes dried, and made a precipitate by spirit of wine. This æthiops animal, in negroes as well as in the cuttle-fish, is more abundant after death than even during life. It may serve either for writing or printing; in the former of which ways the Romans used it. It is said to be an ingredient in the composition of Indian ink, mixed with rice. There are five species.

1. The loligo, or great cuttle, with short arms and long tentacula; the lower part of the body rhomboid and pinnated, the upper thick and cylindric. They inhabit all our seas, where having blackened the water by the effusion of their ink, they abscond, and with their tail leap out of the water. They are gregarious, and swift in their motions: they take their prey by means of their arms, and embracing it, bring it to their central mouth. They adhere to the rocks, when they wish to be quiescent, by means of the concave discs that are placed along their arms.

2. The octopodia, with eight arms, connected at their bottom by a membrane. This is the polypus of Pliny, which he distinguishes from the loligo and sepia by the want of the tail and tentacula. They inhabit our seas, but are most at home in the Mediterranean. In hot climates these are found of an enormous size. The Indians affirm that some have been seen two fathoms broad over their centre, and each arm nine fathoms long. When the Indians navigate their little boats, they go in dread of them; and lest these animals should fling their arms over and sink them, they never sail without an ax to cut them off. When used for food they are served up red from their own liquor, which from boiling with the addition of nitre becomes red. Barthol. says, upon cutting one of them open, so great a light broke forth, that at night, upon taking away the candle, the whole hou e seemed to be in a blaze.

3. The media, or middle cuttle, with a long, slender, cylindric body; tail finned, pointed, and carinated on each side; two long tentacula; the body almost transparent, green, but convertible into a dirty brown; confirming the remark of Pliny, that they change their colour through fear, adapting it, chameleon-like, to that of the place they are in. The eyes are large and smaragdine.

4. The sepiola, or small cuttle, with a short body, rounded at the bottom, has a round fin on each side and two tentacula. They are taken off Flintshire, but chiefly inhabit the Mediterranean.

5. The officinalis, or officinal cuttle, with an ovated body, has fins along the whole of the sides, almost meeting at the bottom, and two long tentacula. The body contains the bone, the cuttle-bone of the shops, which was formerly used as an absorbent. The bones are frequently flung on all our shores; the animal very rarely. The conger-eels bite off their arms, or feet, but they grow again, as does the lizard's tail. They are preyed upon by the plaise. This fish emits (in common with the other species), when frightened or pursued, the black liquor which the antients supposed, by darkening the circumambient wave, concealed it from the enemy; and which they sometimes made use of instead of ink.

This animal was esteemed a delicacy among them; and is eaten even at present by the Italians. Rondeletius gives us two receipts for the dressing, which may be continued to this day. Athenæus also leaves us the method of making an antique cuttle-fish sausage; and we learn from Aristotle, that those animals are in highest season when pregnant.

SEPIARIÆ, (from sepes, a hedge), the name of the 44th order of Linnæus's Fragments of a natural Method, consisting of a beautiful collection of woody plants, some of which, from their size and elegance, are very proper furniture for hedges. See Botany.

SEPTARIÆ, in natural history, a large class of fossils, commonly known by the names of ludus helmontii and waxen veins. They are defined to be fossils not inflammable, nor soluble in water; of a moderately firm texture and dusky hue, divided by several septa or thin partitions, and composed of a sparry matter greatly debased by earth; not giving fire with steel; fermenting with acids, and in great part dissolved by them; and calcining in a moderate fire. Of this class there are two distinct orders of bodies, and under those six genera. The septariæ of the first order are those which are usually found in large masses, of a simple uniform construction, but divided by large septa either into larger and more irregular proportions, or into smaller and more equal ones, called talc. The genera of this order are four: 1. Those divided by septa of spar, called secomiæ: 2. Those divided by septa of earthy matter, called gaiophragmia: 3. Those divided by septa of the matter of the pyrites, called pyritercia: and 4. Those divided by septa of spar, with an admixture of crystal, called diaugophragmia. Those of the second order are such as are usually found in smaller masses, of a crustated structure, formed by various incrustations round a central nucleus, and divided by very thin septa. Of this order there are only two genera: 1. Those with a short roundish nucleus, inclosed within the body of the mass: and, 2. Those with a long nucleus, standing out beyond the ends of the mass.

SEPTAS, a genus of plants belonging to the order of heptagynia, and the class of heptandria, and in the natural system ranged under the 13th order, succulentæ. The calyx is divided into seven parts; the petals are seven; the germens seven; the capsules are also seven, and contain many seeds. There is only one species, the capensis, which is a native of the Cape of Good Hope, is round-leaved, and flowers in August or September.

SEPTENTRIO, in astronomy, a constellation more usually called ursa minor. See Astronomy.

SEPTUM. See Anatomy.

SEQUESTRATION, is the separating or setting aside of a thing in controversy from the possession of both those who contend for it. And it is of two kinds, voluntary or necessary; voluntary is that which is done by consent of each party; necessary is that which the judge does of his authority, whether the parties will or not. It is used also for the act of the ordinary disposing of the goods and chattels of one deceased, whose estate no man will meddle with. A sequestration is also a kind of execution for debt, especially in the case of a beneficed clerk, of the profits of the benefices, to be paid over to him that had the judgment till the debt is satisfied.

Sequestration, in the civil law, is used in various senses; it is taken for the act of the ordinary in disposing of the goods of a deceased person, which nobody will meddle with. A widow is said to sequester, when she disclaims having any thing to do with the estate of her deceased husband. Sequestration is also used to signify the gathering up the fruits of a vacant benefice, for the use of the next incumbent of the church.

SEQUESTRO HABENDO, a writ judicial, for dissolving a sequestration of the fruits of a benefice made by a bishop at the king's command, thereby to compel the parson to appear at the suit of another; for the parson upon his appearance may have this writ for the discharge of the sequestration.

SERAPIAS, a genus of plants belonging to the order of diandria, and to the class of gynandria, and in the natural system arranged under the 7th order, orchideæ. The nectarium is egg-shaped and gibbous, with an egg-shaped lip. The species are 14, of which three are natives of Britain. 1. The latifolia, or broad-leaved helleborine. 2. The palustris, or marsh helleborine, grows in rough boggy pastures and marshes, and flowers in July. 3. The grandiflora, or white-flowered helleborine, grows in woods, and flowers in June.

SERGE, in commerce, a woollen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London serge, which is highly valued abroad.

In the manufacture of London serges, the longest wool is chosen for the warp, and the shortest for the woof. But before either kind is used, it is first scoured, by putting it in a copper of liquor, somewhat more than lukewarm, composed of three parts of fair water, and one of urine. After it has staid in it long enough for the liquor to take off the grease, &c. it is stirred briskly about with a wooden peel, taken out, drained, washed in a running water, and dried in the shade; beaten with sticks on a wooden rack, to drive out the coarser dust and filth, and then picked clean with the hands. It is then greased with oil of olives; and the longest wool combed with large combs, heated in a little furnace, for that purpose: to clear it from the oil, it is put into a vessel of hot soap-water, whence being taken out, wrung, and dried, it is spun on the wheel. As to the shorter wool, intended for the woof, it is only carded on the knee, with small fine cords, and then spun on the wheel, without being scoured of its oil: and here it is to be observed, that the thread for the warp is always to be spun finer, and much better twisted, than that of the woof.

The wool both for the warp and woof being spun, and the thread reeled into skains, that of the woof is put on spools, fit for the cavity of the shuttle; and that for the warp is wound on a kind of wooden bobbins, to fit it for warping; and when warped, it is stiffened with a size, usually made of the shreds of parchments; and when dried, put into the loom, and mounted so as to be raised by four treadles, placed under the loom, which the workman makes to act transversely, equally, and alternately, one after another, with his feet; and as the threads are raised, throws the shuttle. See WEAVING.

The serge, on being taken from the loom, is carried to the fuller, who fulls or scours it, in the trough of his mill, with fuller's-earth; and after the first fulling, the knots, ends, straws, &c. sticking out on either side of the surface, are taken off with a kind of pliers or iron pincers, after which it is returned into the fulling-trough, where it is worked with warm water, in which soap has been dissolved; when quite cleared, it is taken out, the knots are again pulled off; it is then put on the tenter to dry; taking care, as fast as it dries, to stretch it out, both in length and breadth, till it is brought to its just dimensions; then being taken off the tenter, it is dyed, shorn, and pressed.

SERGEANT, or SERJEANT, at law, is the highest degree taken in that profession, as that of a doctor is in the civil law. To these serjeants, as men of great learning and experience, one court is set apart for them to plead in by themselves, which is the court of common pleas, where the common law of England is most strictly observed; yet though they have this court to themselves, they are not restrained from pleading in other courts, where the judges (who cannot be elevated to that dignity till they have taken the degree of serjeant at law) call them brothers, and hear them with great respect, next to the king's attorney and solicitor general. These are made by the king's mandate, or writ.

There are also serjeants at arms, whose office is to attend on the person of the king, to arrest persons of condition offending.

SERGEANT, or *Serjeant*, in war, is an inferior officer in a company of foot, or troop of dragoons, armed with a halberd, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straighten, and form, ranks, files, &c.

SERJEANTY, signifies in law a service that cannot be due from a tenant to any lord, but to the king only; and it is either grand serjeanty or petit serjeanty.

Grand serjeanty, is a tenure whereby a person holds his lands of the king by such services as he ought to do in person; as to carry the king's banner, or his lance, or to carry his sword before him at his coronation, or to do other like services; and it is called grand serjeanty, because it is a more worthy service than the service in the common tenure of escuage.

Petit serjeanty is where a person holds his land of the king, to furnish him yearly with some small thing towards his wars, as a bow, lance, &c. And such service is but socage in effect, because such tenant by his tenure ought not to go nor do any thing in his proper person.

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connection with each other: in this sense we say, a series of emperors, kings, bishops, &c.

SERIES, in mathematics, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion, the doctrine of which has already been given under the article PROGRESSION.

SERIES, *infinite*, is a series consisting of an infinite number of terms, that is, to the end of which it is impossible ever to come; so that let the series be carried on to any assignable length, or number of terms, it can be carried yet farther, without end or limitation.
